

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

DISCUSSION OF THE WORKING HYPOTHESIS THAT THE SO-CALLED ELEMENTS ARE COMPOUND BODIES.*

By J. NORMAN LOCKYER, F.R.S.

It is known to many Fellows of the Society that I have for the last four years been engaged upon the preparation of a map of the solar spectrum on a large scale, the work including a comparison of the Fraunhofer lines with those visible in the spectrum of the vapour of each of the metallic elements in the electric arc.

To give an idea of the thoroughness of the work, at all events in intention, I may state that the complete spectrum of the sun, on the scale of the working map, will be half a furlong long; that to map the metallic lines and purify the spectra in the manner which has already been described to the Society, more than 100,000 observations have been made and about two thousand photographs taken.

In some of these photographs we have vapours compared with the sun; in others vapours compared with each other; and others again have been taken to show which lines are long and which are short in the spectra.

I may state, in way of reminder, that the process of purification consisted in this:—When, for instance, an impurity of manganese was searched for in iron, if the longest line of Mn was absent, the short lines must also be absent on the hypothesis that the elements are elementary; if the longest line were present, then the impurity was traced down to the shortest line present.

The Hypothesis that the Elements are Simple Bodies does not include all the Phenomena.

The final reduction of the photographs of all the metallic elements in the region 39-40—a reduction I began in the early part of the present year, and which has taken six months, summarised all the observations of metallic spectra compared with the Fraunhofer lines accumulated during the whole period of observation. Now this reduction has shown me that the hypothesis that identical lines in different spectra are due to impurities is not sufficient. I shall show in detail in a subsequent paper the hopeless confusion in which I have been landed. I limit myself on the present occasion to giving tables showing how the hypothesis deals with the spectra of iron and titanium.

We find short line coincidences between many metals, the impurities of which have been eliminated or in which the freedom from mutual impurity has been demonstrated by the absence of the longest lines.

Evidences of Celestial Dissociation.

It is five years since I first pointed out that there are many facts and many trains of thought suggested by solar and stellar physics which point to another hypothesis—namely, *that the elements themselves, or at all events some of them, are compound bodies.*

In a letter written to M. Dumas, December 3, 1873, and printed in the *Comptes Rendus*, I thus summarised a memoir which has since appeared in the *Philosophical Transactions*.

“Il semble que plus une étoile est chaude plus son spectre est simple, et que les éléments métalliques se font voir dans l'ordre de leurs poids atomiques.”

“Ainsi nous avons :

“1. Des étoiles très-brillantes où nous ne voyons que l'hydrogène, *en quantité énorme*, et le magnésium ;

“Des étoiles plus froides, comme notre Soleil, où nous trouvons :—

dans ces étoiles, pas de métalloïdes ;

“Des étoiles plus froides encore, dans lesquelles tous les éléments métalliques sont associés, où leurs lignes ne sont plus visibles, et où nous n'avons que les spectres des métalloïdes et des composés.

“4. Plus une étoile est âgée, plus l'hydrogène libre disparaît ; sur la terre, nous ne trouvons plus d'hydrogène en liberté.

“Il me semble que ces faits sont les preuves de plusieurs idées émises par vous. J'ai pensé que nous pouvions imaginer une ‘dissociation céleste,’ qui continue le travail de nos fourneaux, et que les métalloïdes sont des composés qui sont dissociés par la température solaire, pendant que les éléments métalliques monatomiques, dont les poids atomiques sont les moindres, sont précisément ceux qui résistent, même à la température des étoiles les plus chaudes.”

Before I proceed further, I should state that while observations of the sun have since shown that calcium should be introduced between hydrogen and magnesium for that luminary, Dr. Huggins's photographs have demon-

strated the same fact for the stars, so that in the present state of our knowledge, independent of all hypotheses, the facts may be represented as follows, the symbol indicating the spectrum in which the lines are visible.

Hottest stars	Fluted	H + Ca + Mg	
Sun	Bands of	H + Ca + Mg + Na + Fe	
Cooler Stars	Lines of	— — — Mg + Na + Fe + Bi + Hg	
		— — — — — — — — — —	
Coollest..		— — — — — — — — — —	Metalloids

Following out these views, I some time since communicated a paper to the Society on the spectrum of calcium, to which I shall refer more expressly in the sequel.

Differentiation of the Phenomena to be Observed on the Two Hypotheses.

When the reductions of the observations made on metallic spectra, on the hypothesis that the elements were really elementary, had landed me in the state of utter confusion to which I have already referred, I at once made up my mind to try the other hypothesis, and therefore at once sought for a critical differentiation of the phenomena on the two hypotheses.

Obviously the first thing to be done was to inquire whether one hypothesis would explain these short line coincidences which remained after the reduction of all the observations on the other. Calling for simplicity sake the short lines common to many spectra basic lines,

the new hypothesis, to be of any value, should present us with a state of things in which basic molecules representing bases of the so-called elements should give us their lines, varying in intensity from one condition to another, the conditions representing various compoundings.

Suppose A to contain B as an impurity and as an element, what will be the difference in the spectroscopic result?

A in both cases will have a spectrum of its own;

B as an impurity will add its lines according to the amount of impurity, as I have shown in previous papers.

B as an element will add its lines according to the amount of dissociation, as I have also shown.

The difference in the phenomena, therefore, will be that, with gradually increasing temperature, the spectrum of A will fade, if it be a compound body, as it will be increasingly dissociated, and it will not fade if it be a simple one.

Again, on the hypothesis that A is a compound body, that is, one compounded of at least two similar or dissimilar molecular groupings, then the longest lines at one temperature will not be the longest at another, the whole fabric of "impurity elimination," based upon the assumed single molecular grouping, falls to pieces, and the origin of the basic lines is at once evident.

This may be rendered clearer by some general considerations of another order.

General Considerations.

Let us assume a series of furnaces A . . . D, of which A is the hottest.

FIG. 1.*

Let us further assume that in A there exists a substance α by itself competent to form a compound body β by union with itself or with something else when the temperature is lowered.

Then we may imagine a furnace B in which this compound body exists alone. The spectrum of the compound β would be the only one visible in B, as the spectrum of the assumed elementary body α would be the only one visible in A.

A lower temperature furnace C will provide us with a more compound substance γ , and the same considerations will hold good.

Now if into the furnace A we throw some of this doubly compounded body γ we shall get at first an integration of the three spectra to which I have drawn attention; the lines of γ will first be thickest, then those of β , and finally α would exist alone, and the spectrum would be reduced to one of the utmost simplicity.

This is not the only conclusion to be drawn from these considerations. Although we have by hypothesis β , γ , and δ all higher, that is, more compound forms of α , and although the strong lines in the diagram may represent the true spectra of these substances in the furnaces B, C, and D respectively, yet, in consequence of incomplete dissociation, the strong lines of β will be seen in furnace C, and the strong lines of γ will be seen in furnace D, *all as thin lines*. Thus, although in C we have no line which is not represented in D, the intensities of the lines in C and D are entirely changed.

In short, the line of α strong in A is *basic* in B, C, and D, the lines of β strong in B are *basic* in C and D, and so on.

I have prepared another diagram which represents the facts on the supposition that the furnace A, instead of having a temperature sufficient to dissociate β , γ , and δ into α is far below that stage, although higher than B.

FIG. 2.

* The figures between the hypothetical spectra point to the gradual change as the spectrum is observed near the temperature of each of the furnaces.

It will be seen from this diagram that then the only difference in the spectra of the bodies existing in the four furnaces would consist merely in the relative thicknesses of the lines. The spectrum of the substances as they exist in A would contain as many lines as would the spectrum of the substances as they exist in D; each line would in turn be *basic* in the whole series of furnaces instead of in one or two only.

Application of these General Considerations to Impurity Elimination.

Now let us suppose that in the last diagram (FIG. 2) the four furnaces represent the spectra of say, iron, broken up into different finenesses by successive stages of heat. It is first of all abundantly clear that the relative thicknesses of the iron lines observed will vary according as the temperature resembles that of A, B, C, or D. The positions in the spectra will be the same, but the intensities will vary; this is the point. *The longest lines, represented in the diagram by the thickest ones, will vary as we pass from one temperature to another.* It is on this ground that I have before stated that the whole fabric of impurity elimination must fall to pieces on such an hypothesis. Let us suppose, for instance, that manganese is a compound of the form of iron represented in furnace B, with something else; and suppose again that the photograph of iron which I compare with manganese represents the spectrum of the vapour at the temperature of the furnace D. To eliminate the impurity of iron in manganese, as I have eliminated it, we begin the search by looking for the longest and strongest lines shown in the photograph of iron, in the photograph of manganese taken under the same conditions. I do not find these lines. I say, therefore, that there is no impurity of iron in manganese, but although the longest iron lines are not there, some of the fainter basic ones are. This I hold to be the explanation of the apparent confusion in which we are landed on the supposition that the elements are elementary.

Application of these Considerations to Known Compounds.

Now to apply this reasoning to the dissociation of a known compound body into its elements—

A compound body, such as a salt of calcium, has as definite a spectrum as a simple one; but while the spectrum of the metal itself consists of lines, the number and thickness of some of which increase with increased quantity, the spectrum of the compound consists in the main of channelled spaces and bands, which increase in like manner.

In short, the molecules of a simple body and a compound one are affected in the same manner by quantity in so far as their spectra are concerned; *in other words, both spectra have their long and short lines*, the lines in the spectrum of the element being represented by bands or fluted lines in the spectrum of the compound; and in each case the greatest simplicity of the spectrum depends upon the smallest quantity, and the greatest complexity (a continuous spectrum) upon the greatest.

The heat required to act upon such a compound as a salt of calcium so as to render its spectrum visible, dissociates the compound according to its volatility; the number of true metallic lines which thus appear is a measure of the quantity of the metal resulting from the dissociation, and as the metal lines increase in number, the compound bands thin out.

I have shown in previous papers how we have been led to the conclusion that binary compounds have spectra of their own, and how this idea has been established by considerations having for a basis the observations of the long and short lines.

It is absolutely similar observations and similar reasoning which I have to bring forward in discussing the compound nature of the chemical elements themselves.

In a paper communicated to the Royal Society in 1874,

referring, among other matters, to the reversal of some lines in the solar spectrum, I remarked "—

"It is obvious that greater attention will have to be given to the precise character as well as to the position of each of the Fraunhofer lines, in the thickness of which I have already observed several anomalies. I may refer more particularly at present to the two H lines 3933 and 3968 belonging to calcium, which are much thicker in all photographs of the solar spectrum [I might have added that they were by far the thickest lines in the solar spectrum] than the largest calcium line of this region (4226'3), this latter being invariably thicker than the H lines in all photographs of the calcium spectrum, and remaining, moreover, visible in the spectrum of substances containing calcium in such small quantities as not to show any traces of the H lines.

"How far this and similar variations between photographic records and the solar spectrum are due to causes incident to the photographic record itself, or to variations in the intensities of the various molecular vibrations under solar and terrestrial conditions, are questions which up to the present time I have been unable to discuss."

An Objection Discussed.

I was careful at the very commencement of this paper to point out that the conclusions I have advanced are based upon the analogies furnished by those bodies which, by common consent and beyond cavil and discussion, are compound bodies. Indeed, had I not been careful to urge this point the remark might have been made that the various changes in the spectra to which I shall draw attention are not the results of successive dissociations, but are effects due to putting the same mass into different kinds of vibration or of producing the vibration in different ways. Thus the many high notes, both true and false, which can be produced out of a bell with or without its fundamental one, might have been put forward as analogous with those spectral lines which are produced at different degrees of temperature with or without the line, due to each substance when vibrating visibly with the lowest temperature. To this argument, however, if it were brought forward, the reply would be that it proves too much. If it demonstrates that the *h* hydrogen line in the sun is produced by the same molecular grouping of hydrogen as that which gives us two green lines only when the weakest possible spark is taken in hydrogen inclosed in a large glass globe, it also proves that calcium is identical with its salts. For we can get the spectrum of any of the salts alone without its common base, calcium, as we can get the green lines of hydrogen without the red one.

I submit, therefore, that the argument founded on the overtones of a sounding body, such as a bell, cannot be urged by any one who believes in the existence of any compound bodies at all, because there is no spectroscopic break between acknowledged compounds and the supposed elementary bodies. The spectroscopic differences between calcium itself at different temperatures is, as I shall show, as great as when we pass from known compounds of calcium to calcium itself. There is a perfect continuity of phenomena from one end of the scale of temperature to the other.

Inquiry into the Probable Arrangement of the Basic Molecules.

As the results obtained from the above considerations seemed to be so far satisfactory, inasmuch as they at once furnished an explanation of the *basic lines* actually observed, the inquiry seemed worthy of being carried to a further stage.

The next point I considered was to obtain a clear mental view of the manner in which, on the principle of evolution, various bases might now be formed, and then become basic themselves.

It did not seem unnatural that the bases should increase their complexity by a process of continual multiplication, the factor being 1, 2, or even 3, if conditions were available under which the temperature of their environment should decrease, as we imagined it to do from the furnace A down to furnace D. This would bring about a condition of molecular complexity in which the proportion of the molecular weight of a substance so produced in a combination with another substance would go on continually increasing.

Another method of increasing molecular complexity would be represented by the addition of molecules of different origins. Representing the first method by $A + A$, we could represent the second by $A + B$. A variation of the last process would consist in a still further complexity being brought about by the addition of another molecule of B, so that instead of $(A + B)_2$ merely, we should have $A + B_2$.

Of these three processes the first one seemed that which it was possible to attack under the best conditions, because the consideration of impurities was eliminated; the prior work has left no doubt upon the mind about such and such lines being due to calcium, others to iron, and so forth. That is to say, they are visible in the spectra of these substances as a rule. The inquiry took this form. Granting that these lines are special to such and such a substance, does each become basic in turn as the temperature is changed?

I therefore began the search by reviewing the evidence concerning calcium and seeing if hydrogen, iron, and lithium behaved in the same way.

(To be continued)

ANALYSIS OF BOILER FEED-WATERS.

By W. F. K. STOCK, F.C.S., F.I.C.

BEING frequently engaged in the analysis of boiler feed-waters, I have found, as a result of several years' experience, that unless the person to whom a report is submitted happens to be possessed of considerable chemical knowledge, a statement giving an exhaustive analysis of a water residue is apt to be very much more puzzling than edifying, and, as a matter of fact, such an analysis is by no means necessary to the purpose of selecting waters for boiler use. A much more simple method of procedure has stood one in good stead in several difficult cases, and is the one I always follow, of course with modifications to meet special requirements.

Most of the readers of the CHEMICAL NEWS will be familiar with the characteristics of a good boiler water, but for the sake of making more complete the description of the mode of working, I may be allowed to point them out as follow:—

1. Freedom from any very appreciable quantity of suspended mineral matter.
2. Absence of any trace of mineral acids or of acid salts, or corrosive salts of any kind.
3. Absence of oily or fatty substances.
4. A good boiler water should not contain more than 30 grains solids per gallon, and not more than half of this should precipitate on boiling under pressure.

Some little consideration is here due to the statements thus made. For example, the amount of suspended mineral matter a boiler water may contain is, to a great extent, governed by the quantities of carbonates of lime and magnesia, and sulphate of lime it contains, and by the manner in which the boiler is fed. If a water gave a coherent deposit on boiling, I should feel bound to object to more than 2 or 3 grains of mineral matters per gallon in suspension, as tending to augment and harden such deposit; and, again, if a boiler were to be fed without subsidence or filiation, the same objection would hold

good on account of damage to pumping and feed apparatus. With respect to mineral acids or corrosive salts my opinion is that any such contamination ought to condemn a water utterly for boiler purposes, unless simple and effective means could be adopted for their neutralisation.

The action of oils and fats has of late received considerable attention in connection with boiler waters. For some time the opinions respecting their influence were extremely various, but it is now pretty generally acknowledged that their presence is of no possible good, and may lead to very serious harm. The following case, which came under my own observation in March, 1876, may be of interest in this connection. A boiler at a large ironworks in the Cleveland district was being fed with Tees water (a most excellent boiler water), which was slightly heated on its way to the boiler, by the exhaust steam from the blowing engines, with which steam, however, it never came into actual contact. It was observed that after the boiler had been at work for about two years, the feed pipe supplying it with the warmed Tees water became leaky in places not far removed from a flanged joint, the perforations from which the water oozed being like very small pin-holes. The boiler was neighbour to another, having a cast-iron feed pipe, in which no leak whatever existed. The faulty pipe was removed, and put into my hands for examination. I first of all paid attention to the feed water, and, finding no clue there, turned my attentions upon the pipe itself. I had some difficulty in detecting the exterior perforations, but where they occurred the interior of the pipe was eaten away to such an extent that a walnut would have laid in the holes. These holes were filled with spongy masses of what appeared to be ferric oxide, but which upon analysis gave the following results:—

Ferric oxide	=	66.91	per cent
Ferrous	=	23.69	"
Aluminic	=	trace	"
Calcic	=	0.60	"
Magnesian	=	0.70	"
Sulphur trioxide	=	0.22	"
Phosphoric pentoxide	=	0.24	"
Water	=	1.60	"
Organic matter	=	5.31	"
Insoluble	=	1.30	"

100.57

The organic matter yielded oleic acid in quantity, on treatment with ether, and this, coupled with the presence of both ferric and ferrous oxides, and the comparative ease with which wrought-iron filings are attacked by oleic acid in presence of water, when heated under pressure, led me to adopt the following explanation of the corrosion. The presence of the fatty matter must, under the circumstances, be attributed to accident; most probably this had occurred during erection of plant. The first effect of the action of the fatty acid upon the metal was the production of a ferrous salt, which was oxidised by the oxygen existing in solution in the water, the iron only being raised in the scale of oxidation, the fat acid being liberated, and seizing upon another portion of metal, which was again oxidised, and so the action became local and continuous. I do not believe the cast metal pipe would have suffered at all under such circumstances, because the graphite it contained would have protected it from corrosion, and under my advice cast pipes were supplied to all the boilers as a preventive measure. It is seldom, indeed, or never that all the features I have pointed out would occur in any individual sample of water, and as a rule the most the analyst has to do is to indicate what amount of scale-forming matter the sample contains; and when it is called to mind what terrible accidents have occurred, and are constantly happening, through the unadvised use of hard waters, it becomes a matter of the utmost importance to have some reliable and simple method of making this

point clear to steam users. I have placed the limit figure in a water analysis for boiler purposes at 15 per gallon, which number is the result of observation, partly, and of inquiry amongst practical men using which were known to me. Any greater contents lead to more frequent blowing off and chipping than is the and loss of time is the consequence. The evil becomes much worse if attention is withheld, and the ultimate result is local overheating, unequal expansion and traction, culminating either in sudden destruction of boiler, with its too-often attendant horrors, or the boiler becomes utterly leaky and unmanageable. The following is the method I have devised and adopted as embodying the whole of the foregoing, and as furnishing in short time most reliable information as to the character of any given water generally:—

1. The suspended matter is determined by filtering 700 cc. of the water through tared papers. The residue is washed, dried at 110°C., and weighed, burnt and weighed again. The weight in grammes gives grains per gallon, and the difference between first and second weighings gives the suspended matter.
2. The examination for free mineral acids consists in testing the water, which must be rendered clear by filtration, if necessary, with dilute coccolite tincture, and determining the acid so found by decinormal soda. If corrosive salts are suspected they are best arrived at by the evaporative method. A large volume of the water (700 to 1500 c.c.) is concentrated by the action of the concentrated liquid, a weighed strip of pure iron, which should be previously washed with boiled distilled water, is then with strong alcohol, dried, and weighed. The nature of the corrosive substance is, of course, given in the report, with any other information the analyst can supply regarding it.
3. Oily and fatty matters occasion a milky appearance in water containing them, which disappears on treatment with a moderate quantity of ether. The amount of ether or fat is determined by evaporating 350 c.c. of the water-bath (with the addition of one or two drops of dilute sulphuric acid) to about 70 c.c. The residual acid liquid is cooled, digested with ether in a stoppered tube about two centimetres diameter. The ethereal portion is decanted into a watch glass, the acid liquid washed with more ether, which is added to that in the dish, and the etheral solutions evaporated over the water-bath and weighed; and this weight, reported along with the weight of caustic soda needed to render the water clear, or oil, found harmless. It is only in condensed waters that such substances are found as a rule, but however, grease should occur in water, giving lime and magnesia salts, sufficient soda would be required for their removal also.
4. The proportions of solids deposited on boiling under pressure and solids retaining solubility on boiling under pressure, are found by taking an observation of the total solid matter the water contains, by evaporation of 70 c.c. in platinum, and dry at 100°C., is quite sufficiently accurate. It is necessary to boil 700 c.c. of the water for 24 hours in a flask connected by an india-rubber stopper, with an inverted Liebig's condenser fed with cold water. The boiled water is then cooled to temperature at which it was measured, the condenser has received proper attention, and appreciable diminution of volume will have taken place. The cooled water is run through a dry filter, and 70 c.c. are evaporated at 100°C. as before. The difference between the weights of the residues gives solids deposited on simply boiling. We have now to add to this the calcium su-

contained in the boiled and filtered water, because calcium sulphate is practically insoluble at a pressure of one atmosphere of steam. The calcic oxide is determined in 350 c.c. of the boiled and filtered water, calculated into dry sulphate, and added on to solids deposited on boiling. The difference between the number so obtained and the total solids gives solids retaining solubility on boiling under pressure, which solids are only of account in as far as they augment the boiling-point of the residual water. It will of course be obvious that if a water contains free acids, except carbonic, that latter part of the process will be omitted.

I have always viewed the boiling of a water in a thin glass flask as a very excellent method of judging of its scale-forming qualities, and it is quite remarkable to note various peculiarities of deposits so obtained.

In reporting an analysis of boiler water made by this method I adopt the following tabulation:—

	Grains per gal.	Pounds per 100 galls.
Solids deposited by boiling under pressure ..	—	—
Solids remaining in solution on boiling under pressure	—	—

Then follow remarks as to the analyst's opinion of the water generally. I need hardly say that it is the bounden duty of every one who attempts the analysis of boiler water to make himself well acquainted with the construction and manner of working the different makes of boilers in ordinary use, and also to study well the reactions of the various salts natural waters contain when subject to heat and pressure combined. When one views the evidence produced before coroners' juries dealing with cases of death from boiler explosions, it is often very painfully apparent that there is a great deal yet to be done by chemists in the tracing of effect to cause, the information afforded being often of the most meagre quality, and a field of inquiry embracing the salvation of life and property is surely one in which honour is not wanting.

Laboratory and Assay Office, Darlington,
December 19, 1878.

ON THE METHOD OF EXTRACTING GOLD, SILVER, AND OTHER METALS FROM PYRITES.*

By W. A. DIXON, F.C.S., Cor. Mem. Nat. Hist. Soc. Glasgow.
(Concluded from p. 303).

THE method of treatment of the concentrated ore, or regulus, is the same whether the sulphides are rich in the precious metals or not, but requires variation according to—First, the presence or absence of copper; second, the proportion of copper; and, third, the presence or absence of lead.

To begin with the simplest case, viz., with pyrites free from copper. The apparatus required consists of—1, a roaster; 2, a reverberatory furnace; 3, an arsenic flue, (if the pyrites are arsenical); 4, a leaden combination chamber; 5, a leaden condensing tower; 6, a series of lixiviating tanks and coolers. It is best to construct the furnace, roaster, arsenic flue, converting chamber, and tower in one line, so that the waste heat from the reverberatory furnace heats the sole of the roaster and converting chamber. The reverberatory furnace is constructed in the usual manner, but the sole is made simply of brick, and flat, with an opening in the centre or side, through which the charge may be raked out into an iron hopper

waggon. The roaster is built as a muffle, with a sole of brick or cast-iron plates laid at a slight incline, to facilitate the transference of the charges. At the lower end there is a depression of about 6 inches, forming a recess, which extends half way over the reverberatory furnace, and has an opening which can be closed with a slide, through which the contents of the recess may be at once transferred to the furnace. At the end of the roaster is an arsenic flue if required. Farther on is the combination chamber, built of sheet-lead, supported by an external framing of wood; the sole is of sheet-lead, supported on iron plates over the flue. The sole is divided into eight stages, each of which is an inch higher than the one nearer the roaster. Beyond the combination chamber is a condensing tower, which may be built of brick, laid in a putty of clay and coal-tar, or, better, sheet-lead, supported by an external framing of wood. The condenser is filled with coke or pebbles, supported on iron bars covered with lead, allowing a free space for the entry of the gases evolved in the roaster. Surmounting the coke is a perforated sheet of lead, with suitable openings for the escape of the residual gases, which may be conducted by a pipe to a chimney. On the perforated lead plate water is delivered at intervals by a self-acting tumbler, kept supplied by a cistern. The water escaping through the holes in the lead plate is uniformly distributed over the coke, and trickles downwards, escaping over the sole of the combination chamber, flowing over each stage in succession, and from the lowest to a wooden cooler, whence it is again pumped to the cistern.

The roaster should have two or three small fireplaces at intervals underneath the sole, to get it to a working heat, which may be closed when this is attained, the flame from the reverberatory furnace, mixed with a sufficient quantity of air through openings in the flue, then supplying sufficient heat.

The roaster sole being heated to a dull red heat, 2 cwts. of the dressed pyrites, or ground regulus, is mixed with from 10 to 15 per cent of previously roasted ore, and charged into the upper end of the roaster, so that it occupies about 2 feet of the length, and spreads across the sole, which it should cover to the depth of one and a half inches. The ore soon becomes ignited, evolving sulphurous, sulphuric, and arsenious oxides. The last is condensed in the arsenic flue, and the two former pass through the combination chamber to the condensing tower, and are there absorbed by the descending water.

In an hour's time the charge is moved 2 feet to the left, and a second charge of the mixture is placed in the space cleared. At the end of another hour the first charge is moved 2 feet to the left, the second to the space cleared, and a third is introduced, and so on, until at the end of twenty-four hours the sole of the roaster is covered. The upper part of the roaster should be at a very dull red heat, whilst the lower should be sufficiently hot to decompose any sulphate of iron formed.

On the sole of the recess from 35 to 40 lbs. of coal-dust, charcoal-dust, or other carbonaceous matter is now spread, and the calcined residue from the first charge is turned over on top of it, each charge in the roaster is moved downwards, and a fresh charge of mixture introduced. In another hour a similar quantity of carbon is spread on top of the charge in the recess, and the second charge is turned over on top, and so on until eight successive charges of roasted residue and carbon are in the recess.

The contents of the recess are then transferred to the reverberatory furnace through the opening; the whole is well stirred up, and spread over the sole. The furnace is closed, and kept at a moderate red-heat for eight hours, the furnace being kept full of a smoky flame to assist reduction. The oxides are thus reduced to the metallic state, and the heat should be kept so low as to prevent the reduced iron from agglutinating into masses. At the end of eight hours the reduced metal is withdrawn from the furnace at the opening into the hopper waggon, which is immediately closed, so as to prevent access of air. The

* Read before the Royal Society of N.S.W. August 1, 1877.

furnace is again charged from the recess, which has meanwhile been filled.

When the hopper is cool enough to be handled, the contents are rapidly transferred to a vessel containing water, best by placing the waggon over the vessel and withdrawing a slide in its bottom, so as at once to thoroughly wet and cool the contents.

One-eighth part, or thereabouts, of the cooled metal is now placed in the upper stage of the combination chamber, over which water from the condenser, charged with sulphurous and sulphuric acids, is flowing. In one hour the charge is moved to the second stage, and a second charge is introduced, and so on, until in eight hours the chamber is filled, and that furnace charge exhausted. The metal is rapidly acted on by the acids, and converted into sulphate, sulphite, and hyposulphite of iron; but by the combined action of the air and water, assisted by the heat from the flue, the first largely predominates. The charge on the lowest stage is now removed, and may be at once lixiviated with water; but it is best to keep it for a few days in a moist state, to finish the conversion into sulphate. It is then lixiviated with water, which removes sulphate of iron (also zinc, nickel, and cobalt if present), and leaves a residue containing the gold and silver, mixed with quartz, excess of carbon, and free sulphur. The carbon and sulphur are then burned off, and the gold and silver separated from the quartz by washing, amalgamating, or otherwise. If the extraction of the sulphate of iron is effected with boiling water, and the liquor run into coolers, that salt may be obtained in a marketable condition; or, the crystals being calcined at a dull-red heat, yield a fine red oxide of iron suitable for painting, and sulphuric acid, which may be condensed.

If the ores contain copper in small proportion only, the roasting, reduction, and solution of the iron are conducted precisely as above described, using, however, as little carbon as possible for the reduction, so as to obtain the residue nearly free therefrom. The copper is then found in the residue principally as sulphide. This residue is roasted at a dull red heat, and the copper is extracted by treatment with condenser liquor and crystallisation, as described below, the gold and silver being obtained from the residue as before.

Ores or sulphides containing much copper are roasted at a dull red heat, the mixing with roasted ore, roasting, and condensation of the gases being conducted as before. The well-roasted ore is withdrawn from the furnace and cooled. The cooled residue is then shaken into a lixiviating tank partly filled with a solution of sulphate of copper, containing sulphuric acid and sulphurous acid, obtained as below described; the mixture is allowed to digest, and treated with successive portions of the solid solution until the escaping liquor contains free sulphuric acid. The lixiviation is then carried on with a cold saturated solution of sulphate of copper from the coolers, which is made boiling hot in a leaden or copper boiler, until the specific gravity of the entering and escaping solutions is the same. The whole of the copper liquors are run into wooden coolers, where crystals of the sulphates of copper and iron are deposited. When the lixiviation has been carried as far as possible with the copper solution, it is drawn from the tank until it stands only an inch or so above the solid contents, and 12 inches of water are carefully floated on top, and the drawing off the copper solution continued from below until the water is only an inch above the solid contents, when a second wash is run on, and in the same manner a third if necessary. The copper liquors are run to the coolers as long as they mark above 20° of Twaddell, below that strength they are run to a separate tank to be used for the first wash of another lot.

If the ore contains silver, a little is found in solution in the copper liquor, and is separated therefrom by filtering it through a bed or beds of cement copper, or, better, of precipitated sulphide of copper, before running the liquor to the coolers. The silver is recovered from time to time

by toasting the precipitate, extracting the copper by condenser liquor, and melting the residual silver.

The residue in the lixiviating tanks is drained, dried, mixed with one-fourth of its weight of carbon, reduced, and otherwise treated as above described, to obtain the gold and remaining silver.

The crystals of sulphates of copper and iron in the coolers are removed from time to time, drained and dried. One ton of the dried crystals is charged into the muffle furnace, and there exposed to a fully cherry-red heat, so as to convert the whole of the sulphates into oxides. The sulphurous and sulphuric acids evolved are conveyed to the condensing tower, which is supplied with sulphate of copper solution from the coolers, slightly diluted with the weaker wash liquor by which the acids are condensed, and used for extracting roasted ore. When vapours are no longer evolved the calcined residue is removed from the muffle. A similar charge of dried sulphate is heated in the muffle furnace to a dull red, so as to convert the sulphate of iron into oxide, and when fumes are no longer evolved the charge is raked out, mixed with $\frac{1}{2}$ cwts. of coal or charcoal dust, and charged into the reverberatory furnace, where it is melted, when sulphurous and other gases are evolved, causing the mass to boil. When boiling ceases the oxides are added to the charge, and the melting heat continued until the whole is in a tranquil fusion, when the slags are raked off and the rough copper run into moulds.

If the ore contains lead it is found in the residue containing the gold and silver; and if present in sufficient quantity the residue may be smelted, and the gold and silver recovered by cupellation.

If not present in sufficient quantity to smelt, but still so much as to interfere with the amalgamation, the residue is roasted, treated with a little condenser liquor, washed, and the lead extracted with solution of caustic soda, when the gold and silver may be amalgamated. The solution of lead in caustic soda is mixed with sawdust or carbon, evaporated to dryness, heated strongly, and the carbonate of soda dissolved out with water, and again rendered caustic by lime, when the lead remains as an insoluble residue mixed with carbon.

The advantages of this mode of treatment are that the sulphides are entirely got rid of, whilst if through inattention in the roasting some sulphides remain, only the small proportion that has escaped requires to be re-roasted, instead of the whole mass of ore as is usually the case. In the extraction of copper from the sulphides the whole of the copper may be obtained in the form of crystals, from which the copper may be recovered without evaporation of liquors; and in the whole of the operations, with the exception of smelting for copper, the temperatures are so low that the cheapest materials may be used for the construction of furnaces. The temperature being low, the loss of silver by volatilisation is reduced to a minimum, whilst there is absolutely no loss of gold, except through the careless spilling of the material. Lastly, as neither salt, iron, or other material is consumed in the process, a large source of expense in all previous wet methods of treatment is avoided; and the process is adapted for use wherever the ores are found.

PROCEEDINGS OF SOCIETIES.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, November 26, 1878.

J. P. JOULE, D.C.L., LL.D., F.R.S., &c., President, in the Chair.

"On some Improved Methods of Producing and Regulating Electric Light," Part II., by HENRY WILDE.

In a former communication to the Society I directed attention to the fact that when the electric light is produced from the ends of two carbon pencils placed parallel to each other, if the strength of the electric current, the thickness of the carbons, and the distance between them are rightly proportioned, the carbons will burn steadily downwards until they are wholly consumed, without any insulating material between them. To initiate the light by this method it is necessary to complete the electric circuit between the carbons by means of some conducting substance, which volatilises on the passage of the current, and establishes the electric arc between the points.

When a number of such lights are produced simultaneously from the same source of electricity, any interruption in the continuity of the current extinguishes all the lights in the same circuit, and each pair of carbons requires to be re-primed before the lights can again be established. This defect, as will be obvious, would cause great inconvenience when the lights are not easily accessible, or are at considerable distances apart.

In the course of my experiments it was observed that when the electric circuit was completed at the bottom of a pair of carbons close to the holders, the arc immediately ascended to the points, where it remained so long as the current was transmitted. My first impression of this peculiar action of the arc was, that it was due to the ascending current of hot air by which it was surrounded. This, however, was found not to be the cause, as the arc travelled towards the points in whatever position the carbons were placed, whether horizontally or vertically in an inverted position. Moreover, when a pair of carbons were held in the middle of the holders, the arc travelled upwards or downwards towards the points, according as the circuit was established above or below the holders. The action was in fact recognised to be the same as that which determines the propagation of an electric current through two rectilinear and parallel conductors submerged in contact with the terrestrial bed, which was described by me in the *Philosophical Magazine*, August, 1868.

In all the arrangements in general use for regulating the electric light, the carbon pencils are placed in the same straight line, and end to end. When the light is required, the ends are brought into momentary contact, and are then separated a short distance to enable the arc to form between them. The peculiar behaviour of the electric arc when the carbons are placed parallel to each other suggested to me the means of lighting the carbons automatically, notwithstanding the fact that they could only be made to approach each other by a motion laterally, and to come into contact at their adjacent sides. To accomplish this object one of the carbon holders is articulated or hinged to a small base plate of cast-iron, which is so constructed as to become an electro-magnet when coiled with a few turns of insulated wire. The carbon holder is made in the form of a right-angled lever, to the short horizontal limb of which is fixed an armature placed over the poles of the electro-magnet. When the movable and fixed carbon holders are brought into juxtaposition, and the carbons inserted in them, the upper parts of the two carbons are always in contact when no current is transmitted through them.

The contact between the carbons is maintained by means of an antagonistic spring inserted in a recess in one of the poles of the electro-magnet, and reaching on the under side of the armature. One extremity of the coil of the electro-magnet is in metallic connection with the base of the carbon holder, while the other extremity of the coil is in connection with the terminal screw at the base of the instrument, from which it is insulated. The coils of the electro-magnet are thus placed in the same circuit as the carbon pencils.

When the alternating current from an electro-magnetic induction machine is transmitted through the carbons, the electro-magnet attracts the armature and separates the upper ends of the carbons, which brings them into their normal position, and the light is immediately pro-

duced. When the circuit is interrupted the armature is released; the upper ends of the carbons come into contact, and the light is produced as before. When several pairs of carbons are placed in the same circuit they are, by this arrangement, lighted simultaneously.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 24, December 9, 1878.

Report on Mr. Lawrence Smith's Memoir on the Native Iron of Greenland and the Dolerite which it Contains.—MM. Ste.-Claire Deville, Des Cloizeau, and Daubrée.—Mr. Smith concludes that all the native irons of Greenland are mutually similar, and, on the contrary, that they differ from the meteoritic irons. The former are confined to the basaltic region, extending from lat. 69° N. to 76° N., and are most abundant in its best developed regions. It is known that the terrestrial rocks which offer a resemblance to meteorites all belong to the deeper regions of the earth's crust. In those regions of Greenland where native iron occurs layers of lignites underlie here and there the great basaltic deposit, and it is possible that these carbonaceous matters may have partially reduced the iron to the metallic state. Still it is equally possible that the native iron may have been brought up from below, like the native alloy of platinum and iron which is found embedded in peridotite rocks.

Automatic Current-Regulator.—M. Hospitalier.—By means of the author's apparatus the intensity of a current may be maintained between two limits fixed beforehand, and which may be as near together as is desired.

Note on a Remarkable Specimen of Iron Silicide.—J. Lawrence Smith.—The specimen has the appearance of an ingot from the blast-furnace and has a brilliant surface. It resists nearly all reagents except hydrofluoric acid and caustic alkalis at a red heat. It contains 15 per cent of silicium, whilst the alloy of iron and manganese richest in silicium has only 10 per cent. Its origin is unknown.

A New Acid Derived from Camphor.—A. Haller.—The author has obtained a homologue of camphoric acid, which he proposes to name hydroxy-camphobic acid, $C_{11}H_{18}O_4$. It decomposes the alkaline and alkaline-earth carbonates, forming salts with their bases. The author has analysed the salts of lead, copper, and zinc.

Formation of Hexamethyl-benzin by the Decomposition of Aceton.—W. H. Greene.—The author has obtained this product in quantity by the action of aceton upon melted chloride of zinc at a high temperature.

Normal Ethyl-oxy-butyric Acid and its Derivatives.—M. Duvillier.—An examination of the ethyl-oxy-butyrate of methyl and of ethyl-oxy-butyramide.

Presence of Ytterbium in the Sipylite of Amherst (Virginia).—Marc Delafontaine.—The author has isolated from this mineral a base whose characters agree closely with those of M. Marignac's ytterbia.

Existence of Baryta and Strontia in all the Rocks forming Primordial Districts.—M. Dieulafoy.—The author finds that these earths are easily recognised in feldspars, in the mica of primitive rocks, in granites coarse or fine, and in syenite. The author considers that these rocks are the original source of baryta and strontia.

Danger of the Use of Borax for the Preservation of Food, and Causes why certain Substances Deprive

Meat of its Nutritive Properties.—G. Le Bon.—Meat steeped in a solution of pure borax, or covered with the powdered salt, may be preserved unchanged for a long time, but if taken as food such meat produces intestinal derangements, which necessitates its disuse. Borax, taken in small successive doses, is a poisonous agent, the use of which in the preservation of alimentary substances ought to be strictly prohibited. M. Peligot has already pointed out the poisonous action of borax upon plants. Several companies in America, who had begun to use this salt for the preservation of meat, have been obliged to give it up. The author further shows the necessity of avoiding saline substances altogether for the preservation of food, an object which he considers attainable solely by the use of cold.

MISCELLANEOUS.

University of London.—The following are lists of the candidates who have passed the recent examinations:—*Second B.A. and Second B.Sc. Examinations.*—*Examinations for Honours* (B.A. and B.Sc. conjointly).—*Mathematics.* First Class: J. Larmor, B.Sc. (Scholarship), St. John's College, Cambridge; W. H. Gunston,* B.A., St. John's, Cambridge. Third Class: J. A. Owen, B.Sc., private study. *Logic and Psychology.* First Class: W. K. Griffin, B.Sc., University College and private study. Second Class: S. W. Bowser, B.A., University and Regent's Park College; J. Enright, B.Sc. St. Mary's Hospital and King's College; J. Browne, B.A., Stonyhurst College. Third Class: I. Abrahams, B.A., Jews' and University Colleges; R. Gill, B.Sc., St. Bartholomew's Hospital; G. A. Stebbing, B.A., Catholic University College, Kensington; G. E. Ford, B.A., University College; J. W. Greig, B.A., University College; J. J. Beuzemaker, B.A., private study; R. A. Freeman, B.A., private study. *Classics* (B.A. only). First Class: F. C. Montague (Scholarship), Balliol College, Oxford; A. W. Lockyer, private study. Second Class: E. Etherington, Stonyhurst College; G. F. Colborne, private study and tuition; H. H. C. Thurston, Stonyhurst College; T. Slater, Stonyhurst College. Third Class: J. Browne, Stonyhurst College; C. G. Higginson, Owens College; C. T. Galton, Stonyhurst College. *French.* First Class: J. W. Greig (Prize) University College; O. E. Bodington, Giggleswick School and private tuition; F. J. Morrish, Cheshunt College and private study. Second Class: F. P. Hartley, private study; C. G. Higginson, Owens College. Third Class: E. A. Durham, private study; G. Board, private study. *German.* Second Class: C. T. Galton, Stonyhurst; J. T. Christie, King's College, London, and Exeter, Oxford. *Chemistry* (B.Sc. only). R. Gill, St. Bartholomew's Hospital; C. F. Cross, King's and Owens Colleges. *Experimental Physics.* Second Class: L. H. Edmunds, University College. Third Class: M. F. O'Reilly, St. Joseph's College, Clapham; G. W. von Tunzelmann, University College. *Physical Geography and Geology.* Second Class: T. Gough, private study and Royal College of Chemistry. Third Class: G. H. Bailey, University College and private study; P. N. Bose, University College. *Botany.* First Class: T. Gough, private study and Royal College of Chemistry. Third Class: P. N. Bose, University College. *Zoology.* Second Class: S. H. C. Martin, University College.

South London School of Pharmacy.—The sixth Annual Dinner took place at the Horns Assembly Rooms on Friday, the 20th ult. There were about 130 old and new students present, together with a large number of gentlemen interested in the progress of the School. Dr. Julius Pollock presented the prizes to the following successful students:—*Senior Chemistry.*—(Medal) Mr. Pocock; (Certificate) Miss Stammwitz. *Junior Chemistry.*—(Medal) Mr. Harrison; (Certificate) Mr. New-

* Obtained the number of marks qualifying for the Scholarship.

begin. *Botany.*—(Medal) Mr. Lord; (Certificate) Mr. Scammell. *Materia Medica.*—(Medal) Mr. Newbigin; (Certificates) Mr. Lemmon and Mr. Harrison, equal. *Practical Pharmacy and Dispensing.*—(Medal) Mr. Lemmon; (Certificate) Mr. Lord. *Silver Medal of the School, for Session 1877-78.*—Mr. John E. Phillips.

NOTES AND QUERIES.

Asphalte Pitch.—Will any of your correspondents kindly give me any information of the best method of making asphaltic pitch, and the way to make it into "blocks" ready for use?—J. R.

Peroxide of Hydrogen.—Will any of your readers inform me how I can obtain information how to make peroxide of hydrogen of ten volumes strength? I want it for commercial purposes.—THOMAS WARDLE.

Distillation of Tar.—(Reply to R. J.)—The best work on the distillation of tar, &c., is by Dr. George Lunge, published by Vieweg and Sohn, Brunswick.—DESTRUCTIVE DISTILLATOR.

MEETINGS FOR THE WEEK.

MONDAY, Jan. 6th.—Medical, 8.

London Institution, 5.

TUESDAY, 7th.—Mineralogical, at 116, Victoria Street, 8. "On Ptilolite, an unrecognised species," by Prof. M. F. Heddle. "On so-called Green Garnets from the Urals," by Prof. A. H. Church. "On the Magnetism of Rocks and Minerals," by J. B. Hannay, F.C.S. "On the Celestine and Baryto-celestine of Clifton," by J. N. Collie; communicated by W. W. Stoddart. THE CHEMICAL NEWS.

VOL. XXXIX. No. 998.

DISCUSSION OF THE WORKING HYPOTHESIS THAT THE SO-CALLED ELEMENTS ARE COMPOUND BODIES.

By J. NORMAN LOCKYER, F.R.S.

(Concluded from p. 3.)

II.

*Application of the above Views to Calcium, Iron, Lithium,
and Hydrogen.*

Calcium.

was in a communication to the Royal Society made some time ago (*Proc.*, vol. xxii., p. 380, 1874), that I referred to the possibility that the well-known line-spectra of the elementary bodies might not result from vibration of similar molecules. I was led to make the

the spectra of the brighter stars before this point could be determined.

I also remarked that this result enabled us to fix with very considerable accuracy the electric dissociating conditions which are equivalent to that degree of dissociation at present at work in the sun.

In Fig. 3 I have collected several spectra copied from photographs in order that the line of argument may be grasped.

First we see what happens to the non-dissociated and the dissociated chloride. Next we have the lines with a weak voltaic arc, the single line to the right (W. L. 4226.3) is much thicker than the two lines (W. L. 3933 and 3968) to the left, and reverses itself.

We have next calcium exposed to a current of higher tension. It will be seen that here the three lines are almost equally thick, and all reverse themselves.

Now it will be recollected, that in the case of known compounds the band structure of the true compounds is reduced as dissociation works its way, and the spectrum of each constituent element makes its appearance. If in 3 we take the wide line as representing the banded spectrum of the compound, and the thinner ones as representing the longest elemental lines making their appearance as the result of partial dissociation, we have, by hypothesis, an element behaving like a compound.

FIG. 3.—THE BLUE END OF THE SPECTRUM OF CALCIUM UNDER DIFFERENT CONDITIONS.

Calcium is combined with chlorine (CaCl_2). When the temperature is low, the compound molecule vibrates as a whole, the spectrum is at the red end, and no lines of calcium are seen. 2. The line of the metal seen when the compound molecule is dissociated to a slight extent with an induced current. 3. The spectrum of metallic calcium in the electric arc with a small number of cells. 4. The same when the number of cells is increased. 5. The spectrum when a coil and small jar are employed. 6. The spectrum when a large coil and large jar are used. 7. The absorption of the calcium vapour in the sun.

mark in consequence of the differences to which I have already drawn attention in the spectra of certain elements as observed in the spectrum of the sun and in those obtained with the ordinary instrumental appliances.

Later (*Proc. Roy. Soc.*, No. 168, 1876) I produced evidence that the molecular grouping of calcium which, with small induction-coil and small jar, gives a spectrum with its chief line in the blue, is nearly broken up in the sun, and quite broken up in the discharge from a large coil and jar, into another or others with lines in the violet.

I said "another," or "others," because I was not then able to determine whether the last-named lines proceeded from the same or different molecules; and I added that it as possible we might have to wait for photographs of

If the hypothesis be true, we ought to be able not only to obtain, with lower temperatures, a still greater preponderance of the single line, as we do; but with higher temperatures, a still greater preponderance of the double ones, as we do.

I tested this in the following manner:—Employing photography, because the visibility of the more refrangible lines is small, and because a permanent record of an experiment, free as it must be from all bias, is a very precious thing.

Induced currents of electricity were employed in order that all the photographic results might be comparable.

To represent the lowest temperature I used a small induction coil and a Leyden jar only just large enough to secure the requisite amount of photographic effect. To represent the highest, I used the largest coil and jar at my disposal. The spark was then taken between two alu-

* Paper read at the Royal Society, December 12, 1878.

minium electrodes, the lower one cup-shaped, and charged with a salt of calcium.

In the figure I give exact copies of the results obtained. It will be seen that with the lowest temperature only the single line (2) and with the highest temperature only the two more refrangible lines (6) are recorded on the plate.

This proved that the intensity of the vibrations was quite changed in the two experiments.

Perhaps it may not be superfluous here to state the reasons which induced me to search for further evidence in the stars.

It is abundantly clear that if the so-called elements, or, more properly speaking, their finest atoms—those that give us line spectra—are really compounds, the compounds must have been formed at a very high temperature. It is easy to imagine that there may be no superior limit to temperature, and therefore no superior limit beyond which such combinations are possible, because the atoms which have the power of combining together at these transcendental stages of heat do not exist as such, or rather they exist combined with other atoms, like or unlike, at all lower temperatures. Hence association will be a combination of more complex molecules as temperature is reduced, and of dissociation, therefore, with increased temperature there may be no end.

That is the first point.

The second is this:—

We are justified in supposing that our "calcium," once formed, is a distinct entity whether it be an element or not, and therefore, by working at it alone, we should never know whether the temperature produces a single simpler form or more atomic condition of the same thing, or whether we actually break it up into $X + Y$, because neither X nor Y will ever vary.

But if calcium be a product of a condition of relatively lower temperature, then in the stars, hot enough to enable its constituents to exist uncombined, we may expect these constituents to vary in quantity; there may be more of X in one star and more of Y in another; and if this be so, then the H and K lines will vary in thickness, and the extremest limit of variation will be that we shall only have H representing, say X in one star, and only have K representing say Y in another. Intermediately between these extreme conditions we may have cases in which, though both H and K are visible, H is thicker in some and K is thicker in others.

Prof. Stokes was good enough to add largely to the value of my paper as it appeared in the *Proceedings* by appending a note pointing out that "When a solid body such as a platinum wire, traversed by a voltaic current, is heated to incandescence, we know that as the temperature increases not only does the radiation of each particular refrangibility absolutely increase, but the proportion of the radiations of the different refrangibilities is changed, the proportion of the higher to the lower increasing with the temperature. It would be in accordance with analogy to suppose that as a rule the same would take place in an incandescent surface, though in this case the spectrum would be discontinuous instead of continuous. Thus if A, B, C, D, E denote conspicuous bright lines of increasing refrangibility, in the spectrum of the vapour, it might very well be that at a comparatively low temperature A should be the brightest and the most persistent; at a higher temperature, while all were brighter than before, the relative brightness might be changed, and C might be the brightest and the most persistent, and at a still higher temperature E ."

On these grounds Prof. Stokes, while he regarded the facts I mentioned as evidence of the high temperature of the sun, did not look upon them as *conclusive* evidence of the dissociation of the molecule of calcium.

Since that paper was sent in, however, the appeal to the stars to which I referred in it has been made, and made with the most admirable results, by Dr. Huggins.

The result of that appeal is that the line which, according to Prof. Stokes's view, should have prevailed over all

others, as Sirius is acknowledged to be a hotter star than our sun, is that if it exists at all in the spectrum, it is so faint that it was recognised by Dr. Huggins in the first instance.

In Sirius, indeed, the H line due to one molecular grouping of calcium is as thick as are the hydrogen lines as mapped by Secchi, while the K line, due to another molecular grouping, which is equally thick in the spectrum of the sun, has not yet made its appearance.

In the sun, where it is as thick as H , the hydrogen lines have vastly thinned.

While this paper has been in preparation, Dr. Huggins has been good enough to communicate to me the results of his most important observations, and I have also had an opportunity of inspecting several of the photographs which he has recently taken. The result of the recent work has been to show that H and K are of about the same breadth in Sirius. In α Aquilæ while the relation of H to K is not greatly changed, a distinct approach to the solar condition is observed, K being now unmistakably present, although its breadth is small as compared with that of H . I must express my obligations to Dr. Huggins for granting me permission to enrich my paper with reference to these unpublished observations. His letter, which I have permission to quote, is as follows:—

"It may be gratifying to you to learn that in a photograph I have recently taken of the spectrum of α Aquilæ there is a line corresponding to the more refrangible of the solar H lines [that is K], but about half the breadth of the line corresponding to the first H lines.

"In the spectra of α Lyrae and Sirius the second line is absent."

Prof. Young's observations of the chromospheric lines, to which I shall afterwards refer, give important evidence regarding the presence of calcium in the chromosphere of the sun. He finds that the H and K lines of calcium are strongly reversed in every important spot, and that in solar storms H has been observed injected into the chromosphere seventy-five times, and K fifty times, while the blue line at $W. L. 4226.3$, the all-important line at the arc-temperature, was only injected thrice.

Further, in the eclipse observed in Siam in 1875, the H and K lines left the strongest record in the spectrum of

FIG. 4.—THE MOLECULAR GROUPINGS OF CALCIUM.

the chromosphere, while the line near G in a photographic region of much greater intensity was not recorded at all. In the American eclipse of the present year the H and K lines of calcium were distinctly visible at the base of the corona, in which for the first time the observers could scarcely trace the existence of any hydrogen.

To sum up, then, the facts regarding calcium, we have first of all the H -line differentiated from the others by its almost solitary existence in Sirius. We have the K -line differentiated from the rest by its birth, so to speak, in α Aquilæ, and the thickness of its line in the sun, as compared to that in the arc. We have the blue line differentiated from H and K by its thinness in the solar spectrum while they are thick, and by its thickness in the arc while they are thin. We have it again differentiated from them by its absence in solar storms in which they are almost universally seen, and finally, by its absence during eclipses,

while the H and K lines have been the brightest seen or photographed. Last stage of all, we have calcium, distinguished from its salts by the fact that the blue line is only visible when a high temperature is employed, each salt having a definite spectrum of its own, in which none of the lines to which I have drawn attention appear, so long as the temperature is kept below a certain point.

Iron.

With regard to the iron spectrum I shall limit my remarks to that portion of it visible on my photographic plates between H and G. It may be described as a very complicated spectrum, so far as the number of lines is concerned in comparison with such bodies as sodium and potassium, lead, thallium, and the like, but unlike them again it contains no one line which is clearly and unmistakably reversed on all occasions. Compared, however, with the spectrum of such bodies as cerium and uranium the spectrum is simplicity itself.

Now among these lines are two triplets, two sets of three lines each, giving us beautiful examples of those repetitions of structure in the spectrum which we meet with in the spectra of almost all bodies, some of which have already been pointed out by Mascart, Cornu, and myself. Now the facts indicate that these two triplets are not due to the vibration of the same molecular grouping which gives rise to most of the other lines. They are as follows:—In many photographs in which iron has been compared with other bodies, and in others again in which iron has been photographed as existing in different degrees of impurity in other bodies, these triplets have been seen almost alone, and the relative intensity of them, as compared with the few remaining lines, is greatly changed. In this these photographs resemble one I took three years ago, in which a large coil and jar were employed instead of the arc, which necessitated an exposure of an hour instead of two minutes. In this the triplet near G is very marked, the two adjacent lines more refrangible near it, which are seen nearly as strong as the triplet itself in some of the arc photographs I possess, are only very faintly visible, while dimmer still are seen the lines of the triplet between H and k.

There is another series of facts in another line of work. In solar storms, as is well known, the iron lines sometimes make their appearance in the chromosphere. Now if we were dealing here with one molecular grouping, we should expect the lines to make their appearance in the order of their lengths, and we should expect the shortest lines to occur less frequently than the longest ones. Now, precisely the opposite is the fact. One of the most valuable contributions to solar physics that we possess is the memoir in which Prof. C. A. Young records his observation of the chromospheric lines, made on behalf of the United States Government, at Sherman, in the Rocky Mountains. The glorious climate and pure air of this region, to which I can personally testify, enabled him to record phenomena which it is hopeless to expect to see under less favourable conditions. Among these were injections of iron vapour into the chromosphere, the record taking the form of the number of times any one line was seen during the whole period of observation.

Now two very faint and short lines close to the triplet near G were observed to be injected thirty times, while one of the lines of the triplet was only injected twice.

The question next arises, are the triplets produced by one molecular grouping or by two? This question I also think the facts help us to answer. I will first state by way of reminder that in the spark photograph the more refrangible triplet is barely visible, while the one near G is very strong. Now if one molecular grouping alone were in question this relative intensity would always be preserved however much the absolute intensity of the compound system might vary, but if it is a question of two molecules we might expect that in some of the regions open to our observation we should get evidence of cases in which the relative intensity is reversed or the

two intensities are assimilated. What might happen does happen; the relative intensity of the two triplets in the spark photograph is grandly reversed in the spectrum of the sun. The lines barely visible in the spark photograph are among the most prominent in the solar spectrum, while the triplet which is strong in that photograph is represented by Fraunhofer lines not half so thick. Indeed, while the hypothesis that the iron lines in the region I have indicated are produced by the vibration of one molecule does not include all the facts, the hypothesis that the vibrations are produced by at least three distinct molecules includes all the phenomena in a most satisfactory manner.

Lithium.

Before the maps of the long and short lines of some of the chemical elements compared with the solar spectra, which were published in the *Phil. Trans.* for 1873, "Plate IX.," were communicated to the Society, I very carefully tested the work of prior observers on the non-coincidence of the red and orange lines of that metal with the Fraunhofer lines, and found that neither of them were strongly if at all represented in the sun, and this remark also applies to a line in the blue at wave-length 4603.

The photographic lithium line, however, in the violet has a strong representative among the Fraunhofer lines.

Applying, therefore, the previous method of stating the facts, the presence of this line in the sun differentiates it from all the others. For the differentiation of the red and yellow lines I need only refer to Bunsen's spectral analytical researches, which were translated in the *Phil. Mag.*, December, 1875.

In Plate IV. two spectra of the chloride of lithium are given, one of them showing the red line strong and the yellow one feeble, the other showing merely a trace of the red line, while the intensity of the yellow one is much increased, and a line in the blue is indicated. Another notice of the blue line of lithium occurs in a discourse by Prof. Tyndall, reprinted in the *CHEMICAL NEWS*, and a letter of Dr. Frankland's to Prof. Tyndall, dated November 7, 1861. This letter is so important for my argument that I reprint it entire from the *Phil. Mag.*, vol. xxii., p. 472:—

"On throwing the spectrum of lithium on the screen yesterday, I was surprised to see a magnificent blue band. At first I thought the lithic chloride must be adulterated with strontium, but on testing it with Steinheil's apparatus it yielded normal results without any trace of a blue band. I am just now reading the report of your discourse in the *CHEMICAL NEWS*, and I find that you have noticed the same thing. Whence does this blue line arise? Does it really belong to the lithium, or are the carbon points or ignited air guilty of its production? I find there blue bands with common salt, but they have neither the definiteness nor the brilliancy of the lithium band. When lithium wire burns in air it emits a somewhat crimson light; plunge it into oxygen, and the light changes to bluish white. This seems to indicate that a high temperature is necessary to bring out the blue ray."

"POSTSCRIPT, Nov. 22, 1861.—I have just made some further experiments on the lithium spectrum, and they conclusively prove that the appearance of the blue line depends entirely on the temperature. The spectrum of lithic chloride, ignited in a Bunsen's burner flame, does not disclose the faintest trace of the blue line; replace the Bunsen's burner by a jet of hydrogen (the temperature of which is higher than that of the Bunsen's burner) and the blue line appears faint, it is true, but sharp and quite unmistakable. If oxygen now be slowly turned into the jet, the brilliancy of the blue line increases until the temperature of the flame rises high enough to fuse the platinum, and thus put an end to the experiment."

These observations of Profs. Tyndall and Frankland differentiate this blue line from those which are observed

at low temperatures. The line in the violet to which I have already referred is again differentiated from all the rest by the fact that it is the only line in the spectrum of the sun which is strongly reversed, so far as our present knowledge extends. The various forms of lithium, therefore, may be shown in the following manner.

FIG. 5.—THE MOLECULAR GROUPINGS OF LITHIUM.

It is remarkable that in the case of this body which at relatively low temperature goes through its changes, its compounds are broken up at the temperature of the Bunsen burner. The spectrum, *e.g.* of the chloride, so far as I know, has never been seen.

Hydrogen.

All the phenomena of variability and inversion in the order of intensity presented to us in the case of calcium can be paralleled by reference to the knowledge already acquired regarding the spectrum of hydrogen.

Dr. Frankland and myself were working together on the subject in 1869. In that year (*Proc.*, No. 112) we pointed out that the behaviour of the *k* line was *hors ligne*, and that the whole spectrum could be reduced to one line, F.

"1. The Fraunhofer line on the solar spectrum, named *k* by Ångström, which is due to the absorption of hydrogen, is not visible in the tubes we employ with low battery and Leyden-jar power; it may be looked upon, therefore, as an indication of relatively high temperature. As the line in question has been reversed by one of us in the spectrum of the chromosphere, it follows that the chromosphere, when cool enough to absorb, is still of a relatively high temperature.

"2. Under certain conditions of temperature and pressure, the very complicated spectrum of hydrogen is reduced in our instrument to one line in the green corresponding to F in the solar spectrum."

As in the case of calcium also, solar observation affords us most precious knowledge. The *k* line was missing from the protuberances in 1875, as will be shown from the accompanying extract from the Report of the Eclipse Expedition of that year:—

"During the first part of the eclipse two strong protuberances close together are noticed; on the limb towards the end these are partially covered, while a series of protuberances came out at the other edge. The strongest of these protuberances are repeated three times, an effect of course of the prism, and we shall have to decide if possible the wave-lengths corresponding to the images. We expect *a priori* to find the hydrogen lines represented. We know three photographic hydrogen lines: F, a line near G, and *k*. F is just at the limit of the photographic part of the spectrum, and we find indeed images of protuberances towards the less refrangible part at the limit of photographic effect. For, as we shall show, a continuous spectrum in the lower parts of the corona has been recorded, and the extent of this continuous spectrum gives us an idea of the part of the spectrum in which each protuberance line is placed. We are justified in assuming, therefore, as a preliminary hypothesis, that the least refrangible line in the protuberance shown on the photograph is due to F, and we shall find support of this view in the other lines. In order to determine the position of the next line the dispersive power of the prism was investigated. The prism was placed on a goniometer table in minimum deviation for F, and the angular distance between F and the hydrogen line near G, *i.e.*, Hy,

was found, as a mean of several measurements to be 3'. The goniometer was graduated to 15", and owing to the small dispersive power, and therefore relatively great breadth of the slit, the measurement can only be regarded as a first approximation. Turning now again to our photographs, and calculating the angular distance between the first and second ring of protuberances, we find that distance to be 3' 15". We conclude, therefore, that this second ring is due to hydrogen. We, therefore, naturally looked for the third photographic hydrogen line, which is generally called *k*, but we found no protuberance on our photographs corresponding to that wave-length. Although this line is always weaker than Hy, its absence on the photograph is rather surprising, if it be due to the fact that the line is one which only comes out at a high temperature. This is rendered likely by the researches of Frankland and Lockyer (*Proc. Roy. Soc.*, vol. xvii., p. 453).

"We now turn to the last and strongest series of protuberances shown on our photographs. The distance between this series and the one we have found reason for identifying with Hy is very little greater than that between H β and Hy. Assuming the distances equal, we conclude that the squares of the inverse wave-lengths of the three series are in arithmetical progression. This is true as a first approximation. We then calculated the wave-length of this unknown line, and found it to be approximately somewhat smaller than 3957 tenth-metres. No great reliance can be placed, of course, on the number, but it appears that the line must be close to the end of the visible spectrum.

"In order to decide if possible what this line is due to, we endeavoured to find out both by photography and fluorescence whether hydrogen possesses a line in that part of the spectrum. We have not at present come to any definite conclusion. In vacuum tubes prepared by Geissler containing hydrogen, a strong line more refrangible than H is seen, but these same tubes show between Hy and H δ , other lines known not to belong to hydrogen, and the origin of the ultra violet line is therefore difficult to make out. We have taken the spark in hydrogen at atmospheric pressures, as impurities are easier to eliminate, but a continuous spectrum extends over the violet and part of the ultra-violet, and prevents any observation as to lines. We are going on with experiments to settle this point.

"Should it turn out that the line is not due to hydrogen, the question will arise what substance it is due to. It is a remarkable fact that the calculated wave-length comes very close to H. Young has found that these calcium lines are always reversed in the penumbra and immediate neighbourhood of every important sun-spot, and calcium must therefore go up high into the chromosphere. We draw attention to this coincidence, but our photographs do not allow us to draw any certain conclusions.

"At any rate, it seems made out by our photographs that the photographic light of the protuberances is in great part due to an ultra-violet line which does not certainly belong to hydrogen. The protuberances as photographed by this ultra-violet ray seem to go up higher than the hydrogen protuberances, but this may be due to the relative greater length of the line."

In my remarks upon calcium I have already referred to the fact that the line which our observation led us to believe was due to calcium in 1875, was traced to that element in this year's eclipse. The observations also show the curious connection that, at the time when the hydrogen lines were most brilliant in the corona, the calcium lines were not detected; next, when the hydrogen lines, being still brilliant, the *k* line was not present (a condition of things which, in all probability, indicated a reduction of temperature), calcium began to make itself unmistakably visible; and finally, when the hydrogen lines are absent, H and K become striking objects in the spectrum of the corona.

To come back to *k* then, I have shown that Dr. Frank-

land and myself, in 1869, found that it only made its appearance when a high tension was employed. We have seen that it was absent from among the hydrogen lines during the eclipse of 1875.

I have now to strengthen this evidence by the remark that it is always the shortest line of hydrogen in the chromosphere.

I now pass to another line of evidence.

I submit to the Society a photograph of the spectrum of indium, in which, as already recorded by Thalén, the strongest line is one of the lines of hydrogen (*h*), the other line of hydrogen (near *G*) being absent. I have observed the *C* line in the spark produced by the passage of an induced current between indium poles in dry air.

As I am aware how almost impossible it is to render air perfectly dry, I made the following differential experiment. A glass tube with two platinum poles about half an inch apart was employed. Through this tube a slow current of air was driven after passing through a U-tube one foot high, containing calcic chloride, and then through sulphuric acid in a Wolff's bottle. The spectrum of the spark passing between the platinum electrodes was then observed, a coil with five Grove cells and a medium-sized jar being employed. Careful notes were made of the brilliancy and thickness of the hydrogen lines as compared with those of air. This done, a piece of metallic indium which was placed loose in the tube, was shaken so that one part of it rested against the base of one of the poles, and one of its ends at a distance of a little less than half an inch from the base of the other pole. The spark then passed between the indium and the platinum. The red and blue lines of hydrogen were then observed both by my friend, Mr. G. W. Hemming, Q.C., and myself. Their brilliancy was most markedly increased. This unmistakable indication of the presence of hydrogen, or rather of that form of hydrogen which gives us the *h* line alone associated into that form which gives us the blue and red lines, showed us that in the photograph we were not dealing with a physical coincidence, but that in the arc this special form of hydrogen had really been present; that it had come from the indium, and that it had registered itself on the photographic plate, although ordinary hydrogen persistently refuses to do so. Although I was satisfied from former experiments that occluded hydrogen behaves in this respect like ordinary hydrogen. I begged my friend, Mr. W. C. Roberts, F.R.S., chemist to the Mint, to charge a piece of palladium with hydrogen for me. This he at once did, and I take this present opportunity to express my obligation to him. I exhibit to the Society a photograph of this palladium and of indium side by side. It will be seen that one form of hydrogen in indium has distinctly recorded itself on the plate, while that in palladium has not left a trace. I should add that the palladium was kept in a sealed tube till the moment of making the experiment, and that special precautions were taken to prevent the two pieces between which the arc was taken becoming unduly heated.

To sum up, then, the facts with regard to hydrogen; we have *h* differentiated from the other lines by its appearance alone in indium; by its absence during the eclipse of 1875, when the other lines were photographed; by its existence as a short line only in the chromosphere of the sun, and by the fact that in the experiments of 1869 a very high temperature was needed to cause it to make its appearance.

With regard to the isolation of the *F* line I have already referred to other experiments in 1869, in which Dr. Frankland and myself got it alone.* I exhibit to the Society a globe containing hydrogen which gives us the *F* line without either the red or the blue one.

The accompanying drawing shows how these lines are integrated in the spectrum of the sun.

I have other evidence which, if confirmed, leads to the conclusion that the substance which gives the non-

reversed line in the chromosphere and the line at 1474 of Kirchhoff's scale, termed the coronal line, are really other forms of hydrogen. One of these is possibly more simple than that which gives us *h* alone, the other more complex than that which gives us *F* alone. The evidence on this point is of such extreme importance to solar physics, and throws so much light on star structure generally, that I am now engaged in discussing it and shall reserve it for a special communication.

FIG. 6.

In the meantime I content myself by giving a diagram in which I have arranged the various groupings of hydrogen as they appear to exist, from the regions of highest to those of lowest temperature in our central luminary.

FIG. 7.

Summation of the above Series of Facts.

I submit that the facts above recorded are easily grouped together, and a perfect continuity of phenomena established on the hypothesis of successive dissociations analogous to those observed in the cases of undoubted compounds.

The other Branches of the Inquiry.

When we pass to the other possible evolutionary processes to which I have before referred, and which I hope to discuss on a future occasion, the inquiry becomes much more complicated by the extreme difficulty of obtaining pure specimens to work with, although I should remark that in the working hypothesis now under discussion the cause of the constant occurrence of the same substance as an impurity in the same connection is not far to seek. I take this opportunity of expressing my obligations to many friends who have put themselves to great trouble in obtaining specimens of pure chemicals for me during the whole continuance of my researches. Among these I must mention Dr. Russell, who has given me many specimens prepared by the lamented Matthiessen, as well as some of cobalt and nickel prepared by himself; Prof. Roscoe, who has supplied me with vanadium and caesium alum; Mr. Crookes, who has always responded to my call for thallium; Mr. Roberts, chemist to the Mint, who has supplied me with portions of the gold and silver trial plates and some pieces of palladium; Dr. Hugo Müller, who has furnished me with a large supply of electrolytically-deposited copper; Mr. Holtzman, who has provided me with cerium, lanthanum, and didymium prepared by himself; Mr. George Matthey, of the well-known metallurgical firm of Johnson and Matthey, who has provided me with magnesium and aluminium of marvellous purity; while to Mr. Valentin, Mr. Mellor, of Salford, and other friends, my thanks are due for other substances.

I have already pointed out that a large portion of the work done in the last four years has consisted in the elimination of the effects of impurities. I am therefore aware

* See also Plücker, *Phil. Trans.*, 1865, part 1, p. 21.

of the great necessity for caution in the spectroscopic examination of various substances. There is, however, a number of bodies which permit of the inquiry into their simple or complex nature being made in such a manner that the presence of impurities will be to a certain extent negligible. I have brought this subject before the Royal Society at its present stage, in the hope that possibly others may be induced to aid enquiry in a region in which the work of one individual is as a drop in the ocean. If there is anything in what I have said, the spectra of all the elementary substances will require to be re-mapped and re-mapped from a new standpoint; further, the arc must replace the spark, the photography must replace the eye. A glance at the red end of the spectrum of almost any substance incandescent in the voltaic arc in a spectroscopic of large dispersion, and a glance at the maps prepared by such eminent observers as Huggins and Thalén, who have used the coil, will give an idea of the mass of facts which have yet to be recorded and reduced before much further progress can be made.

In conclusion, I would state that only a small part of the work to which I have drawn attention is my own. In some cases I have merely, as it were, codified the work done by other observers in other countries. With reference to that done in my own laboratory, I may here repeat what I have said before on other occasions, that it is largely due to the skill, patience, and untiring zeal of those who have assisted me. The burthen of the final reduction, to which I have before referred, has fallen to Mr. Miller, my present assistant; while the mapping of the positions and intensities of the lines was done by Messrs. Friswell, Meldola, Ord, and Starling, who have successfully filled that post.

I have to thank Corporal Ewings, R.E., for preparing the various diagrams which I have submitted to the notice of this Society.

ON SUPERSATURATED SOLUTIONS.

By J. G. GRENFELL.

In September, 1877, Professor Tomlinson read a paper before the Royal Society, the main object of which was to upset the conclusions to which I had been led by my experiments on supersaturated solutions, and thus to maintain his theory that the salt adheres to a film of any greasy substance, while the water does not, and thus separation ensues.

Before answering this paper I wished to repeat some of my experiments, and this I have not been able to do till quite recently. Those conclusions of mine which are openly or implicitly attached in the paper are as follows:—

1. Supersaturated solutions can in many cases be exposed to the air for an indefinite time, can be rubbed with dust or oil and yet not crystallise. At a meeting of the Chemical and Physical Section of the Bristol Naturalists' Society I treated strong solutions of sodium sulphate and acetate in this way, and a good many persons present did the same. I used ordinary castor oil.
2. Absorbent substances, when not at once saturated by the solution, and provided the absorption is not too rapid, cause crystallisation, sometimes as the normal salt, sometimes as a modified salt. For instance, I recently put a considerable quantity of a 6 to 1 solution of sodium carbonate on a new sheet of thick blotting-paper. In about a minute it gave a cake of the modified 7-atom salt. The crystals were quite inactive in a 2 to 1 solution. At the same time I put 13 small drops round the edge; of these two crystallised at once as the 7-atom salt, and they and the central mass were soon quite dry; the rest remained liquid exposed to air

for many hours. In this case the rapidity of the absorption prevented the formation of crystals. Swedish filter-paper generally gives the normal salt in the centre with this solution, whilst any number of small drops are absorbed, and a great many little bits of the paper can be put into drops or into the flask, and are inactive because saturated at once.* The absorbents seem to act by abstracting water. This explains the action of aerial nuclei; they act by causing gentle absorption, which gives the normal salt, or possibly by gentle evaporation. There is some reason to believe that gentle evaporation will give the normal salt just as the more rapid evaporation of drops exposed to air gives a salt with less water. Salts vary very much in their sensitiveness to absorbents, sodium sulphate being the most so that I have yet tried.

3. I believe that most cases of sudden crystallisation on removing cotton-wool, or piercing a bladder, or on giving a jerk, as Professor Tomlinson does to flatten a lens of oil into a film, or (as has often happened to me) on simply entering the room, may be explained thus:—After heating a solution convection currents of air may be seen rising and carrying drops of the solution. These settle on the cover or round the mouth, crystallise there by absorption or evaporation, and are shaken down by any sudden jar. When the covers are loose, or are gently removed, crystallisation seldom follows.

Turning now to Prof. Tomlinson's paper, I find that he has repeated a certain number of my experiments, with the result, as he believes, of upsetting my theories. As a matter of fact, I have to thank him for a very pretty set of illustrations of them.

With regard to the first point, for instance—that of exposure—he finds as I did that drops of sodium acetate can be exposed for weeks, the carbonate for days, the sulphate for many hours on paper and other surfaces. He makes a great point of the fact that this happens only in damp weather; in dry weather he says the drops crystallise. Nearly half of his paper is devoted to experiments which prove this statement. He does not, however, attempt to explain on his own theory why this should be the case, but remarks that laborious investigation is needed to determine the conditions under which bodies do or do not act as nuclei. I could not have wished for a neater proof that my theory is correct. If the nuclei act by absorption and evaporation it is obvious that they will have much less effect in wet weather than in dry. I could have predicted the result, though I have never paid special attention to the point.

I should like to know, however, what Prof. Tomlinson means by saying that drops crystallise in dry weather. There is some reason to believe that he was satisfied with seeing crystals after the lapse of a certain time, and did not try to find out what the crystals were.

This certainly seems to be the case in one instance. He says that potash alum crystallised into an opaque white mass or into transparent crystals in concentric circles round a central pit. Now the alums generally evaporate on glass, giving a more or less transparent crust with a central depression, underneath which little botryoidal masses are often formed. It is not at all common for alum to crystallise in concentric rings of separate crystals, and if, as I suppose, Prof. Tomlinson refers to the ordinary crust, he would find that this is not alum at all, as it is quite inactive in drops, while the merest trace of the normal converts it into the opaque white normal alum.

Be this, however, as it may, it is not hard to account for the statement that in dry weather the drops crystallise rapidly. It is impossible to succeed in dry weather with-

* These experiments so were shown at the meeting mentioned above.

out taking certain precautions. The rough glass plate must have been recently washed, so as to saturate with moisture the absorbent substances which exist in the depressions of the glass, and which are not rubbed off when the surface is wiped dry. If these are allowed to dry thoroughly they start crystallisation in the depressions of the plate; the crystals grow sometimes very rapidly, sometimes very slowly. In the latter case scratching with a sharp point brings the crystals into contact with the solution, which solidifies at once.

This may account for a good many of Prof. Tomlinson's negative results. It also explains his statement that drawing a sharp edge across the drops generally makes them crystallise. If the plate is in the right condition, they do not do so. I have drawn sharp points across hundreds of drops of the strongest solutions in all kinds of weather without causing crystallisation.

It is also necessary in the case of the alums or sodium acetate to clean the sharp point after every experiment with boiling water or preferably a red heat. Cold water and wiping will not generally clean a penknife for instance, owing to the great adhesiveness of the salt.

Next, with regard to rubbing with oil, which is really the crucial test for Prof. Tomlinson's theory, he seems to have been satisfied with rubbing the sulphate with oil on a glass plate; he very naturally found that it crystallised. I had extreme difficulty at first in getting this experiment to succeed, and I could not do so at all in my laboratory, where the dust possibly contains sodium sulphate. But I did succeed completely in another room.

However, if Prof. Tomlinson will wash his hands he may do what I have just done, *i.e.*, rub a little castor oil on the palm of the hand, and then rub in drops of a 3 to 1 solution of the sulphate without its crystallising. He may repeat this with sodium acetate of any strength. Strong sodium carbonate will give a modified salt which is quite inactive in a 6 to 1 solution, and is, therefore, neither the normal nor 7-atom salt. I have succeeded with the alums also, but they are difficult to manage.

Secondly, as direct evidence against the absorption theory, Prof. Tomlinson gives the following experiments: Three pieces of dried sponge were introduced into flasks of the sulphate, and were inactive. Of course they were, being saturated at once. Curiously enough, he actually describes the converse of this experiment, which is needed to maintain my theory. He found some years ago that when sponge is drawn rapidly over the surface, the solution crystallises on the sponge, while that in the flask did not. The only inference he draws from this is that results are often contradictory.

He mentions one more fact as bearing on this point. A solution of the sulphate crystallised when poured on the soil of his garden. This is the very same experiment which first led me to work at the absorption theory. I found, as described in *Nature*, that lumps of earth could be put freely into the flask; but I also found that every single drop put on the earth in the beds crystallised at once.

Similarly with regard to the third point, the effect of sudden jars, Prof. Tomlinson gives experiments which simply confirm my results. He begins thus: "There is one point upon which all observers down to the time of Mr. Grenfell are agreed, namely, that if a supersaturated solution boiling in a flask be tied over with bladder and left until cold, it will, if the bladder be pierced, immediately become solid. Indeed, this has long been a common lecture-room experiment. But Mr. Grenfell goes far beyond anything I or previous observers have done; he exposes these solutions, &c." He thus distinctly implies that I have denied the fact. Of course I have never denied it at all. In my first paper in the *Proc. Roy. Soc.*, two years ago, I carefully explained that I had been driven to abandon cotton-wool, which was generally recommended as a covering, because I felt convinced that in removing it I shook down some crystals. I added that by using loose paper covers I found that the solutions very

seldom crystallised when uncovered. Having thus saddled me with an opinion I have almost expressly repudiated, Prof. Tomlinson proceeds to upset me by the following evidence. He took two flasks of the sulphate; pierced the bladder of one, and it crystallised; he removed the cover of the other in the country, and it remained liquid during a long walk. This, as usual, supports my views. Removing the cover quietly is a very different process to piercing with a pin, and no crystals were shaken down. In the same way he shook a solution of alum several times without shaking down any crystals, but piercing with a pin was effectual. Alum is an adhesive salt, and requires a jerk to be given. Again he pierced the bladder of two flasks of the sulphate, and only one crystallised. On increasing the opening next day to the size of a pea, the other solution crystallised in a few hours. Possibly an absorbent nucleus got in through the enlarged opening, but it is more probable that the crystals round the opening effloresced and some fragment fell in. I have found the effloresced sulphate invariably active. In air it never gets quite free from the normal salt.

To sum up: the great majority of the experiments described in this paper confirm my theories. Prof. Tomlinson arrived at negative results in other cases from not knowing the precautions which have to be taken.

The fact that paper, earth, and all kinds of substances can be introduced into the flasks; that drops will remain liquid on all kinds of surfaces for hours; even granting, which I do not, that it is only in wet weather, and the experiments with oil are absolutely fatal to any theory based on preferential adhesion of the salt to a greasy surface.

The immediate production of the modified seven atom carbonate by blotting-paper, the experiments with sponge and earth, the effect of damp weather on aerial nuclei, and a multitude of similar results which I could give if necessary, are incapable of explanation on any other theory than that of the abstraction of water by absorbent bodies.

The old theory which made the air a store-house of all kinds of crystals is dead and buried. I frequently have half a dozen plates covered with drops of various solutions exposed to air in my laboratory for hours or days, and the drops evaporate quietly as modified salts, or remain liquid. The minutest trace of a crystal makes them crystallise at once.

UPON THE ALTERATION OF STANDARD AMMONIUM CHLORIDE SOLUTION WHEN KEPT IN THE DARK.

By ALBERT R. LEEDS, Ph.D.

In February, 1877, MM. Schloesing and Muntz communicated to the French Academy (*Comptes Rendus*, lxxiv., 301), the results of elaborate experiments tending to prove that nitrification was due in certain cases to the action of an organised ferment. They further showed that nitrification could be arrested in such cases by the vapour of chloroform, and would not set up again until after the filtered sewage employed had been freshly "seeded" by the washings of a soil which was known to nitrify. These observations were verified and extended by R. Warington (*CHEM. NEWS*, xxxvi., 262, 1877), who showed that chloroform and carbon disulphide effectually prevent nitrification in certain cases, while carbolic acid is probably effective to the extent in which it comes in contact with the soil. Moreover that the action of the nitrifying body does not occur at all in the light, darkness being apparently essential. In a note upon the ferment theory of nitrification, by Prof. F. H. Storer (*CHEM. NEWS*, xxxvii., 268), he states that a solution of ammonium chloride, which had been prepared ten or twelve months

previously, gave a strong reaction for nitrites. It had been preserved in a half-filled glass-stoppered bottle, put away in a dark cupboard. Similar solutions, seeded in various ways, but left in a strong light for a number of months, gave no reaction whatever for nitrites or nitrates. The following experiments confirm these results, so far as the change of the ammonium solutions in the dark is concerned, and give the rate at which it may be expected to occur under ordinary circumstances.

A standard solution of ammonium chloride had been prepared October 15th, 1877, by dissolving 0.7867 grm. NH_4Cl , purified by repeated sublimation, in a litre of redistilled water, free from ammonia. Another solution was prepared by diluting 100 c.c. of this water to 1 litre, and used constantly during the months of October and November, 1877, in making the estimations which will be found recorded in an article entitled "Contributions from the Laboratory of the Stevens Institute of Technology." They were put aside in a dark closet, and remained there until this autumn, when a new standard ammonium chloride solution was prepared from the fear that the old solutions had altered. This proves to have been the case. A careful determination, as ammonio-platinic chloride of the ammonia contained in 250 c.c. of the stronger solution, gave 0.0575 grm. or 0.00023 grm. in 1 c.c., instead of 0.00025, the amount which the solution originally contained. Instead of being perfectly limpid, as it was when made, the solution contained a number of white filaments, looking like the vestiges of some vegetable growth. The more dilute solution presented the same appearances, but not to so marked a degree. 25 c.c. of the solution were used in the examination for nitrites, but their presence could not be shown in this large quantity of the liquid. 5 c.c. of the solution were evaporated three times to dryness in a platinum dish with 0.1 grm. of caustic soda, prepared from sodium, and which had been found entirely free from nitrogen compounds. It was then distilled with 6 grms. pig-iron in a vessel entirely made of glass, the pig-iron having been previously repeatedly distilled with water, until it and the vessel had ceased to give any reaction for ammonia. The distillate contained 0.03 m.grm. H_2N equivalent to 0.11 m.grm.; HNO_3 , or 0.022 m.grm.; HNO_3 per cubic centimetre.

ACTION OF POTASSIUM PERMANGANATE UPON OXALIC ACID.

By ALBERT R. LEBDS, Ph.D.

In a paper entitled "Ozone and the Atmosphere,"† I stated that when the two solid substances, crystallised oxalic acid and potassium permanganate in powder, were mixed together, they liberated ozone on addition of water. Vacation intervening, the study of this and similar reactions was not resumed until five months later, in October of last year, when it was found that other organic acids yielded the same apparent results, more especially tartaric and acetic acids. The deportment of the inorganic acids varied: nitric acid, added to potassium permanganate, liberated a gas plentifully, which affected the potassium iodide papers, but the gas evidently contained nitrous acid, and when passed through water had no effect upon the test papers. Hydrochloric acid gave negative results, but chromic acid produced with the permanganate an apparently copious evolution of ozone.

An attempt was then made to determine the amount of ozone apparently given off. 20 grms. of pulverised oxalic acid were introduced into a half-litre flask, which was provided with a glass-funnel and stopcock for the introduction of a saturated solution of potassium permanganate, and an exit tube connecting with a wash-bottle con-

taining water. The corks used in this and the other experiments were boiled in paraffin, and the joints luted with the same. The escaping gas, after passing through the wash-bottle, was made to traverse a Geissler absorption apparatus, containing a decinormal solution of potassium iodide. The action was allowed to go on for a week at common temperatures, the permanganate being added in successive portions until the oxalic acid was completely decomposed. Nine litres of air were drawn through the apparatus, after which the flask was gently warmed and 9 litres more of air drawn through it. No change whatever had taken place in the potassium iodide. The entire experiment was carefully repeated with identical results.

This unexpected conclusion threw suspicion on the methods of ozone-generation, in which potassium permanganate is decomposed by an acid, and more particularly that in which sulphuric acid is employed. For this reason the same apparatus was used as in the above experiment, but 25 grms. pulverised permanganate were introduced into the flask and sulphuric acid run in through the funnel a drop at a time. Much caution was used in conducting the operation, but even then one flask was blown to pieces, after the reaction had been going on for several hours. In each of three trials the potassium iodide remained unchanged, but chlorine was found in the wash-water. This led to an examination of the reagents employed, with the result of finding that the potassium permanganate contained 0.164 per cent of potassium nitrate, and 7.47 per cent of other impurities, principally potassium chlorate, but along with it some manganic oxide, insoluble silicious residue, and a minute amount of potassium chloride. A trace of chlorine was likewise found in the oxalic acid. Analyses of other nominally chemically pure preparations were made with similar results, the least impure containing 97.06 per cent potassium permanganate, with 0.148 per cent chlorate, a trace of chloride, some manganic oxide and sand. The percentage of manganese, in the potassium permanganate first spoken of, determined gravimetrically by precipitation as sulphide, solution in hydrochloric acid, re-precipitation as carbonate and estimation as proto-sesquioxide, was 31.50 per cent, instead of 34.66, the theoretical amount. The manganese percentage determined volumetrically by means of ammonio-ferrous sulphate was 32.78, showing the influence of the admixture of chlorate upon the oxidation of the iron.

At this stage of the enquiry I found that the same sources of error had previously been exposed by C. Rammelsberg (*Berichte der Deutsch. Chem. Gesell.*, vi., p. 604), who showed that the potassium permanganate, which he experimented upon, contained only 27.3 per cent of manganese, the difference being due to 21.6 per cent of potassium perchlorate. He also found that when the permanganate, free from chlorine, was used, no smell was developed by the action of sulphuric acid, and the reaction upon iodo-starch was so weak that it evidently arose from a trace of chlorine.

ON THE WORKING OF MILD STEEL.

By SERGIUS KERN, M.E., St. Petersburg.

MANY experiments prove that mild steel, before being rolled into plates or bars, may be heated to a light welding heat, without the least fear of the ingot crumbling into pieces, which often happens with burnt steel. Altogether many persons are rather afraid of this method of working steel, and prefer to heat the ingots only to a white non-welding heat. This inferior mode of working has given rise to a large percentage of bad products, especially when plates are prepared, and plates with surface defects are certainly rejected. For cheap boiler and ship plates Bessemer steel is at the present time in constant use, and

* *Proceedings Amer. Chem. Soc.*, vol. ii.
† *CHEMICAL NEWS*, xxviii., p. 224.

the chief difficulty in obtaining clean plates in this case are the numerous blow-holes found in the outer parts of the ingots. The rolling of such ingots only masks these defects to a certain extent, as the small marks of their presence in the ingot may be always found in the finished plate. Often slag, scale, and small pieces of sand or brick laying on the surface of the ingot while it is in the furnace fall down into the blow-holes, and are rolled together with the ingot; such plates, with slag and brick particles rolled into the metal, must be certainly condemned for most purposes.

In order to avoid these inconveniences the following means are in the hands of the operator:—

1. The compressing of the liquid steel after casting in order to obtain sound ingots.
2. Hammering the ingots before the rolling of them.
3. Heating the ingots to a mild welding heat.

Compressing of the steel in liquid state must be effectual, but as the hydraulic press used for this purpose is very expensive, the ordinary prices of Bessemer steel, worked in such a manner, must be to a certain extent increased. Next the maintenance of the press, requiring a powerful engine and a couple of boilers, is also dear.

The hammering of the ingots before the rolling of them is cheap, and the work may be done in the Bessemer shop immediately after casting if a steam hammer may be placed in or near the casting house. The work requires a small amount of time, and the ingots, liberated from their moulds in 8 to 20 minutes after the casting of them, may be hammered, without placing them for this purpose into a furnace. After such an operation the surface blow-holes are smoothened and have no action on the surface of plates; this has been remarked during several trials.

The process of welding the steel is the cheapest way of doing away with the surface defects. The metal superficially welds, and when rolled gives a plate with a clean surface. For this purpose gas furnaces or ordinary reheating furnaces with blast may be used. The ingot is covered with sand and remains in the furnace till the scale runs off. Next it is rolled as quickly as possible. This method is even cheaper than the ordinary way of heating the ingots in furnaces without blast to a white non-welding heat. Certainly great care must be taken not to overheat the ingots, and a clever man must look after the furnace.

The burning of the carbon out of the metal is trifling during the heating of the ingot (1½ to 2 hours), as show the following analyses of plates worked by this method:—

Per cent of Carbon.

Ingots.	Plates.
0·24	0·20
0·24	0·19
0·25	0·21

Such plates have a beautiful shining surface, perfectly clean, and give a higher percentage of elongation.

A NEW FORM OF WASH-BOTTLE.

By M. H. FOYE.

In this wash-bottle the blow-tube consists of three parts—A, D, E (see sketch). A and E are pieces of glass tube. A passes through the stopper obliquely, outside the bottle, is bent at *b*, and terminates at *c*. E is bent as shown, and passes through the stopper to the interior of the bottle. D is a piece of caoutchouc tubing which stretches across the top of the stopper and connects A and E. Now it will be seen that by the action of the forefinger upon D, the blow-tube can be closed and opened at pleasure. The advantages of this arrangement are the following:—

1. That after you create a pressure on the liquid in the bottle by flowing through the blow-tube, you can, by compressing the caoutchouc tubing, maintain

this pressure, without continual blowing, until it expends itself by expelling liquid from the jet.

2. The disagreeable reflux of steam into the mouth when washing with hot water, of ammonia or acid fumes when using solutions of either of the latter, can be completely prevented.
3. The flow of liquid from the tube A, when it is desired to use the bottle in that way, can be so accurately regulated by pressing the caoutchouc tubing that it is particularly valuable for diluting, filling measuring vessels, &c.

The jet I use, and which has been suggested by a friend, needs a word of explanation. It is bent, as shown, at *F*, and attached to the tube G, which dips into the liquid in the bottle, by a thick piece (thick enough to maintain

the jet in position) of caoutchouc tubing, H, by turning which round G, the jet can be directed upwards, downwards, or sideways, as desired.

This wash-bottle can be used in every respect like the ordinary wash-bottle, and as conveniently, besides having the advantages described above. It has been used for the last nine or ten months by myself and others in the laboratory at Crewe, and has given every satisfaction. It is not at all liable to get out of order, and is but slightly more difficult to make than the ordinary form of bottle.

8, Martha Terrace, Henry Street, Crewe.

REACTIONS OF
IODINE AND OF POTASSIUM IODIDE
WITH SULPHUROUS ACID.

By ALBERT E. MENKE.

JOHNSON, in his investigation of potassium tri-iodide, noticed that on mixing strong solutions of potassium iodide and sulphurous acid, a yellow colour was produced, which was not bleached by more sulphurous acid, but disappeared on adding water. Gmelin ("Handbook of Chemistry," Watts, ii., 263) states, on the authority of Saladin (*Journ. Chim. Med.*, vii., 528), that hydriodic and sulphurous acids in aqueous solution form a yellow liquid, brighter in proportion to the concentration, and from which, eventually, sulphur is separated. Having myself verified this statement, I inferred that the yellow colour

given by potassium iodide with sulphurous acid was due to the action of the latter upon the hydriodic acid set free, and I was anxious to isolate the substance causing the colour. That it could not be iodine was shown by its resisting the action of excess of sulphurous acid, and by its not colouring carbon disulphide. When the yellow solution was shaken with ether, the latter was very slightly coloured, but on adding a little alcohol and again shaking the ethereal layer acquired a bright yellow colour, and when drawn off and evaporated it left a brown oily substance, having a pungent odour somewhat resembling that of bromine. On heating moderately it evolved vapour of iodine. I made several attempts to obtain it in a state fit for analysis, but the yield was always small, and there was a tendency to the separation of plates of iodine. I therefore tried to obtain it by the action of sulphurous acid gas upon iodine dissolved in ordinary alcohol, hoping that, the quantity of water present being very small, a larger quantity of the yellow substance would be produced. One ounce of iodine was dissolved in 20 c.c. of alcohol, and sulphurous acid was passed in to complete saturation; the liquid remained of a dark brown colour, which disappeared immediately on adding excess of water. As it did not deposit anything after some days, and was found to contain a little free iodine, small quantities of water were added, and more sulphurous acid gas was passed in until no more free iodine could be detected, although the liquid had still a dark brown colour. On standing it deposited a plastic substance resembling the amorphous form of sulphur. This was freed by pressure from adhering mother-liquor, when it weighed 0.140 grm. On oxidising it with fuming nitric acid and precipitating with barium chloride it gave barium sulphate corresponding to 60 per cent of sulphur. Though disappointed in isolating the substance, I submit that my experiments justify the conclusion that the yellow body formed when sulphurous acid acts upon concentrated solutions of potassium and sodium iodide is an unstable iodide of sulphur, and I would suggest the following equations explaining the reaction:—

- (1.) $KI + H_2SO_3 = HI + KHSO_3$.
- (2.) $8HI + 2SO_2 = 4H_2O + I_6 + I_2S_2 (?)$
- (3.) $I_2 + 2H_2O + SO_2 = 2HI + H_2SO_4$.

Chemical Laboratory, King's College, London.

NOTICES OF BOOKS.

A Treatise on Chemistry. By H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S. Vol. II. Metals. Part I. London: Macmillan and Co.

THIS is one of those books most valuable to the student, but the despair of the reviewer. We have no novel and questionable theories to criticise, no new facts of capital importance to point out. On the other hand, it will not be expected that the work of two chemists of such eminence can be rich in errors. We might, indeed, on careful examination come upon statements which we should hesitate to endorse. We may here and there think that some piece of information which has been omitted ought to have been given, and it would certainly be no difficult matter to select from the pages before us interesting facts not to be met with in those chemical hand-books, manuals, and treatises which have lately become somewhat too numerous. The book has, indeed, a distinctive character. Its illustrations, in their number, excellence, and accuracy, have few rivals. They are, further, not restricted to sketches of the apparatus used in the scientific laboratory or at the lecture-table, but include careful representations of the furnaces and other plant as now actually used in the best-arranged chemical manufactories and metallurgical establishments, with the additional recommendation of being drawn to scale. Such impor-

tant processes as the manufactures of alkali and of bleaching-powder, are also described, if not so as to enter into every nicety, still in a manner which has in it no trace of the careless and the perfunctory. In these important respects the work is advantageously distinguished even as compared with such valuable treatises as those of Gmelin and Watt. Let any one, for instance, read the brief section on artificial soda in Gmelin (vol. iii., p. 79), and he will know how to appreciate the difference. Even some professedly technological works give less thorough descriptions of the various stages of the alkali manufacture than does the work before us. This feature is, we hold, of extreme value. Before the scientific chemist can bring his theoretical knowledge to bear usefully upon any of the industrial arts he should have an accurate general knowledge of their nature; of the various portions of the plant and of their functions, and of the difficulties which have been, or which still have to be overcome. Now, without wishing to convey the impression that mere reading can at once put the student in possession of practical knowledge, we hold that a young man fresh from college and entering upon the position of a "work's chemist," will find himself much sooner at home and do himself more credit if the work of Profs. Roscoe and Schorlemmer has been his guide than if he has merely been accustomed to manuals which scarcely condescend to refer to manufacturing operations. We believe that "theory with practice" is the key-word to industrial success, and in that conviction we congratulate the authors on their undertaking.

Coal, its History and Uses. By Professors GREEN, MIALI, THORPE, RUCKER, and MARSHALL, of the Yorkshire College. Edited by Prof. THORPE. London: Macmillan and Co. 1878.

TOWARDS the close of the year 1877 it was suggested to the Professors of the Yorkshire College that by delivering a series of lectures in some of the larger towns of the West Riding they might aid in the good work which is being done by Dr. Gilchrist's educational bequest. Each lecturer was fain to choose his own topic, the whole of them agreeing that, considering the locality in which they were to lecture, they could not select a better general subject than coal. Early in 1878, therefore, a series of ten lectures was delivered in Leeds and Keighley in the following order:—Lectures I. and II., on the Geology of Coal, by Prof. Green; III. and IV., on Coal Plants and Animals, by Prof. Miall; V. and VI., on the Chemistry of Coal, by Prof. Thorpe; VII. and VIII., on Coal as a Source of Warmth and Power, by Prof. Rücker; and IX. and X., by Prof. Marshall, on the Coal Question. The present volume consists of these ten lectures altered in form, revised and arranged consecutively in ten chapters. The only ones affecting our readers are those of Prof. Thorpe, who has managed to introduce a certain amount of fresh detail into this most hackneyed subject by giving a popular account of Mr. J. W. Thomas's researches on the gases occluded in coal. He also gives an interesting description of the successive steps in the invention of the Davy lamp, illustrated by diagrams. Mr. Ansell's fire-damp alarm is also fully described and illustrated. The lectures are illustrated with nearly sixty well-executed cuts. A full index is appended.

Year-Book of Pharmacy. Comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals from July 1, 1877, to June 30, 1878, with the Transactions of the British Pharmaceutical Conference at the 15th Annual Meeting. London: J. and A. Churchill, 1878.

THE ninth volume of the "Year-Book of Pharmacy," as usual, has appeared somewhat late. The book contains abstracts of papers relating to pharmacy contributed to British and foreign journals for the year ending June 30,

1878, and the Proceedings of the British Pharmaceutical Conference which held their sittings in the middle of August. According to the statement which Prof. Attfield made at the meeting held on August 12th, the MS. of the book was to have been laid upon the table on the following day; we cannot, therefore, understand why so long a period as three months and a half should be allowed to elapse before the appearance of the book, even supposing that the Transactions of the Conference were not included in the MS. mentioned by Prof. Attfield. The first part of the work is, as usual, particularly copious and complete, and gives us all the information contained in the principal pharmaceutical and medical journals issued in England and America during the period referred to in a condensed form.

The second part of the work, containing the Proceedings of the Conference, shows that the working members of that body have applied the wholesome lesson read to them by Prof. Attfield at the 1877 meeting, and we are glad to see that every paper, without exception, is of a thoroughly practical character from the pharmacist's point of view. The place of honour is occupied by the paper of Dr. Alder Wright and Mr. A. P. Luff, on the aconite alkaloids. Those improved processes for purifying the aconite bases have led to unexpected results. Thus, the substance described by them last year under the name of pseudaconitine is not a definite base, but a mixture of pseudaconitine and apopseudaconitine, the latter being a dehydrated derivative of the former. The substance again which was last year regarded as pseudaconine is now distinguished as apopseudaconine, and is a dehydrated derivative of true pseudaconine. True aconitine also forms a similar series of dehydrated derivatives. The veratrum alkaloids seem likely to afford a similar series of bases. The alkaloid or alkaloids obtained from *aconitum ferox* are still a puzzle. In any case they appear to differ both from aconitine and pseudaconitine. The outcome of all these apparently recondit researches is of the highest possible practical importance, hitherto the pharmacist has been unable to present the physician with any preparation of either British or foreign aconite root which had a constant composition, but now, as the result of the investigations of Dr. Wright and his colleagues, the active principle of the drug will be procurable in a form whose composition will be nearly as definite as that of potassium nitrate. Mr. Shenstone's researches on the action of nitric acid on strychnine seem to disprove Prof. Sonnenschein's alleged discovery of the formation of brucine by this method, and would also lead us to suppose that pure brucine has not yet been procured. Most of the other papers are of too technical a nature for notice in our pages.

A Pocket-book for Chemists, Chemical Manufacturers, Metallurgists, Dyers, Distillers, &c. By THOMAS BAYLEY, Assoc. R.C.Sc.I., Demonstrator of Practical Chemistry, &c., in the Mining School, Bristol. London: Spon and Co. 1878.

A HANDY little book that has long been wanted, and of whose usefulness it would be needless to say anything. Hitherto chemists have been obliged to fall back on the very incomplete little note-book of Gutch or the French *Addenda* of Dunod, and it seems surprising that the want has never been supplied. The tables, of course, begin with a list of the elements, their symbols, atomicities, and atomic weights; but why, we may ask, are the latter repeated twice? once according to the latest determinations, and again according to some obsolete table. The space thus wasted might have been devoted to the date of the discovery of the newer elements and the names of their discoverers. Various other tables, data, and formulæ follow, one of the most useful being a table of coefficients giving the amount of the constituent sought by simple multiplication. Another is a table for the conversion of grammes into grains and *vice versa*, from 1000 grammes to

1 milligramme, and from 1 grain to 1000 grains. The thermometrical tables range from 263° C., 208° R., and 500° F., down to -10° C., -1° R., and +14° F. The barometrical tables range from 27 inches to 30.98 inches. Boiling points, specific gravities, vapour densities, and solubilities follow. The tables showing the specific gravities of solutions of salts, &c., of different strengths, are particularly copious, but we cannot understand why it is that the temperature at which the specific gravities have been taken differ in every instance. The analytical tables are also very full. The pages on chemical manipulation might, we think, have been omitted. The glossary of minerals, giving their names, formulæ, hardness, specific gravity, and crystalline system, will render Mr. Bayley's little book indispensable to the mineralogist. We have throughout tested Mr. Bayley's *vade mecum* for tables of every sort and kind, and have every one down even to a ready-reckoner and wages table. The 421 pages which the book contains literally team with information, and we think it will puzzle Mr. Bailey to add very much to his second edition, which cannot fail to appear very speedily. The type in which the tables are printed is clear, though necessarily small in cases where much matter is crowded together, and there appear to be but few misprints.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 24, December 9, 1878.

Artificial Pyroxene (Diopside).—L. Gruner.—Crystals of this mineral have been obtained from bricks very rich in lime and magnesia, after being exposed for some time to an intense heat in a furnace.

Influence of Atmospheric Electricity upon the Fructification of Plants.—L. Grandeau.—Atmospheric electricity in two sets of experiments conducted at Nancy and at Mettray decidedly promotes fructification.

Disease of the Coffee-tree Observed in Brazil.—C. Jobert.—This affection, the symptoms of which are minutely described, attacks chiefly plantations in moist and shady situations, and appears to be caused by *Anguillula* which attack the roots.

Diffusion of Heat by Leaves.—M. Maquenne.—The green organs of plants diffuse a considerable proportion of the heat-rays which they receive, this action being almost always accompanied by imperfect reflection, the reflected rays being polarised in the plane of incidence. The proportion of rays diffused in the case of normal incidence diminishes with the temperature of the source of heat.

The Power of Kinds of Wood in Absorbing Water.—E. J. Maumené.—The author finds the proportion of water absorbed by different sorts of wood varies from 9.37 to 174.86 per cent.

No. 25, December 16, 1878.

Observations on M. Pasteur's Paper on Alcoholic Fermentation.—M. Berthelot.—The author, feeling himself reflected upon by M. Pasteur's remarks on the posthumous essays of Claude Bernard, has undertaken a novel and interesting experiment. He writes, "when speaking of a soluble alcoholic ferment capable of being consumed step by step with its production and in the very chemical act which it determines, I took care to add that, for the demonstration of this hypothesis, it would be necessary to discover the conditions in which this ferment is produced in more considerable proportions than the quantity destroyed in fermentation. Such were the con-

ditions which C. Bernard seems to have met with in the experiments, the account of which has unfortunately reached us in so imperfect a manner. Nevertheless, I considered it useful to science to publish them, such as they are, with the object not of opening a controversy but of pointing out a new path for research." By simultaneously hydrogenising and oxidising sugar M. Berthelot has in fact succeeded in producing alcohol, though in very small proportions. He considers that his present results do not warrant a definite conclusion, for the limit may be due as much to the inaccuracy of the fundamental hypothesis as to the imperfection of the conditions. Still, he considers the fact that alcohol has been produced in the cold by the electrolysis of a solution of sugar merits to be placed on record.

Novel Phenomenon of Static Electricity.—E. Duter.—In reply to the memoir of M. Govi (December 2) the author does not admit that his researches can be viewed as a continuation of those of the Italian physicist.

Artificial Production of Nepheline and Amphigene.—F. Fouqué and A. Michel Lévy.—These minerals have been obtained by the same method used by the authors for the reproduction of feldspars.

Spectrometric Measurement of High Temperatures.—A. Crova.—The spectrometric study of the luminous radiations emitted by incandescent bodies has led the author to the discovery of a new method of determining elevated temperatures by the analysis of the light which they emit. If we take, in the continuous spectra of light emitted by two incandescent sources, the one of known temperature, T , and the other of unknown temperature, x , two simple radiations of very different wavelengths, λ and λ' , to which we may refer all our measurements, and determine by means of a spectro-photometer the ratios—

$$\frac{I}{I'} \text{ and } \frac{i}{i'}$$

of the intensity of the two rays λ and λ' in the two spectra. The quotient of these two ratios represents the ratio of the intensities of the ray λ' in the two spectra when the more intense has been lowered so as to give the same intensity to the ray λ in the two spectra.

Specific Heat and Melting Temperature of Palladium.—J. Violle.—The mean specific heat of palladium at $100^\circ = 0.0592$. Its melting temperature is 1500° .

Influence of Temperature on Rotatory Magnetic Power.—J. Joubert.—In the author's experiments the rotatory power was found to increase with the rise of temperature.

Density of Coefficients of Expansion of Liquid Chloride of Methyl.—MM. C. Vincent and Delachanal.—The sp. gr. at $-23.7^\circ = 0.9945$; at $+39^\circ = 0.87886$. The values found for the three coefficients α , β , γ , respectively, are 0.00193929 , 0.0000183121 , and 0.00000105916 .

Oxidation of Certain Aromatic Derivatives.—A. Etard.—On oxidising various organic compounds by means of chromic chlorhydrate the author observed very different reactions, and found that its mode of action is principally regulated by the nature of the body acted upon and by that of the substituted groups which it contains. Thus there are formed acetons, aldehyds, and quinons, whilst hydrochloric acid, or even chlorine, is liberated as an accessory product; in other cases there is no escape of gas, an immediate and total combination being formed.

Nature of Certain Crystalline Secondary Products Obtained in the Industrial Treatment of Pennsylvanian Petroleum.—L. Prunier and R. David.—Among these accessory products are found the carburetted derivatives of acetylen and benzin (anthracen, chrysen, &c.) discovered in the products of the distillation of coal.

Hæmocyanin, a New Substance from the Blood of Octopus vulgaris.—L. Fredericq.—The liquid portion of the blood of the cuttles contains a colourless albumenoid substance, forming with oxygen an unstable compound of a deep blue colour. This substance plays, in the respiration of the cuttles, the same part as does hæmoglobin in that of the Vertebrata. The veinous blood of the cuttles is colourless, but the arterial is a dark blue. If hæmocyanin is ignited it leaves an ash rich in copper, which seems to be in the same condition and to fulfil the same functions as does iron in hæmoglobin.

Influence of the Different Colours of the Spectrum on the Development of Animals.—E. Yung.—Referring to earlier researches on this subject the author states that M. Beclard placed the eggs of *Musca carnaria* under glasses of different colours, and remarked that they were developed very unequally, those under the blue and violet ray being the most developed, and those under the green ray the least so. He arranges the rays, as regards the development of larvæ, in the following order:—Violet, blue, red, yellow, white, green. The author has carried on for three years a series of observations on the eggs of the common and esculent frog, of the trout, and of *Lymnaea stagnalis*. These eggs were placed in vessels plunged respectively into violet, blue, green, yellow, red, and white solutions, whilst one vessel was kept in a dark closet. Violet light accelerates the development in a remarkable manner, and is followed in this respect by the blue, the yellow, and the white. Red and green light appear injurious, as the author was not able to obtain the complete development of ova in these colours. Darkness did not hinder development, but retarded it, contrary to the results of Higginbottom and MacDonnell. The colours may be arranged in the following series of diminishing activity:—Violet, blue, yellow, and white (which are nearly equal), darkness, red, and green. Tadpoles deprived of food died more rapidly of inanition under the violet and blue rays than under the others. The general mortality seemed lowest in white light.

Gazzetta Chimica Italiana.
Anno viii., 1878. Fasc. vi. and vii.

Crystalline Form of Usnic Acid.—P. Freda.—The same remark applies to this memoir.

Preparation of Digallic Acid.—Dr. P. Freda.—A criticism on the method proposed by Prof. Hugo Schiff. The author finds that on heating gallic acid with arsenic acid, whether in alcoholic or aqueous solution, a substance is obtained having some reactions similar to tannic acid. This substance constantly contains arsenic acid, and if this is removed the compound is re-converted into gallic acid.

On α -Iso-chloro-butyric Acid and some of its Derivatives.—L. Balbiano.—The derivatives are oxy-iso-butyric, metacrylic, and dibutylic acids.

New Phenomena Observed in "Plastering" Wines and Musts.—Prof. E. Pollacci.—Sulphate of lime reacts solely upon the cream of tartar, producing acid sulphate of potassa, which remains in solution, while tartrate of lime is formed and is chiefly deposited. The reaction between the two salts is not complete, since there may be found in the liquid both sulphate of lime and cream of tartar. If the gypsum is in large excess a part of it is deposited among the tartrate of lime.

Les Mondes, Revue Hebdomadaire des Sciences.
No. 14, December 5, 1878.

Agoraphobia.—Dr. Legrand du Saule.—The author has studied a novel nervous affection, which manifests itself in a dread of open spaces.

Biedermann's Central-blatt.
Heft 12.

Researches on the Influence of Artificial Manures upon the Growth of Summer Barley.—Dr. G. Marek.—The author concludes that on fruitful soils artificial manures are untrustworthy for barley. Unmanured plots often yield better results than such as are manured.

Experiments with Sugar Beets in Different Soils and with Different Manures.—Dr. J. Hanamann.—The author draws no conclusions from his experiments.

Composition of Wool and Hair.—P. Schutzenberger.—From *Comptes Rendus*, 1878, pp. 767-69.

On Certain Animated Enemies of Cultivated Plants and their Destruction.—M. Schaefer.—An account of certain insects hostile chiefly to the vine. Among the remedies proposed are sodium sulphide, petroleum, and a mixture of an alcoholic extract of tobacco, with bisulphide of carbon.

Wine-Testing and Chemical Analysis.—Drs. E. Mach and Patele.—The authors show that wines on analysis often display properties not suspected from their taste. Sorts rich in alcohol are often pronounced light, and others strongly acid seem mild, &c. These seeming contradictions are due to the fact that wine is a most complicated liquid, whose components are by no means all known. Even among the recognised and more prominent ingredients, it is not so much the quantity of one or the other as their relative proportion which determines the flavour.

On the Influence of Temperature in Malting.—A. Prantl and Hans von der Planitz.—Not susceptible of useful abstraction.

Oino-Chemical Researches.—Dr. M. Buchner.—In order to solve the question whether a given wine is natural or fictitious, in the former certain proportions prevail between the quantities of extract, alcohol, and ash. If the relative proportion of these constituents vary from the normal standard, or if the total is too high or too low, the case is suspicious.

A Source of Error in the Determination of Fat in Milk.—Dr. L. Maneth and Dr. G. Musso.—The authors maintain that if milk, evaporated down along with sand, is extracted with ether, the ether driven off, the residue again extracted with ether and driven off, and the final residue extracted with sulphide of carbon, there remain certain strongly acid drops, of a yellow or deep red colour, soluble in ether and water, but insoluble in fat or in sulphide of carbon. At 100° they take a darker colour and become almost resinous. The authors consider them as impure lactic acid. In recent milk there is little of this substance, and hence there is very little difference between the weight of the residue from the original extraction with ether and that of the residue from the evaporation of sulphide of carbon. There is more difference in old milks, and especially in cheese. The authors state that in milk evaporated to dryness at high temperatures there occurs a wax-like matter, sparingly soluble in ether, which greatly impedes and protracts the process of extraction. (The editor of the *Milch-Zeitung*, from which the above paper is taken, does not find a double extraction of the milk residue with ether requisite. If a proper apparatus is used, the first ethereal extract is perfectly clear, and leaves on evaporation clear fat, in which no drops of foreign matter are present).

Investigations on the Nitrogenous Food of Fungi.—Th. Schlösing and A. Müntz.—From the *Comptes Rendus*, 1878, p. 892.

Analysis of Stag and Roe Horns and of the Horns of an Ox.—Prof. W. Vesely.—Stag, 50.480 ash, 7.88 moisture; fallow-deer, 50.640 ash, 8.98 moisture; roe, 47.830 ash, 9.42 moisture; ox, 1.167, 8.75 moisture—the difference in each case being organic matter. The ash contained:—

	Stag.	Fallow deer.	Roe.	Ox.
Lime	51.96	52.29	52.13	31.60
Magnesia ..	1.02	0.96	1.26	3.60
Phosph. acid ..	42.19	41.41	40.60	12.60
Carbonic acid ..	2.12	2.29	2.98	—
Potash	0.56	1.13	0.89	5.50
Soda	0.30	—	—	—
Sulph. acid ..	0.18	0.09	0.07	6.80

Silica	0.04	0.05	0.09	1.90
Ferric oxide ..	0.79	0.30	0.02	20.30 (?)
Carbon	—	—	—	1.36

MISCELLANEOUS.

Russian Scientific News.—At the Technical Society of St. Petersburg M. Latchinoff delivered a very interesting lecture on the electric light. He made some experiments with Jablochkoff's condensators, which consist of a set of tin plates placed one on another; the surface of every plate is 0.7 square metre. Between every pair of such plates a piece of silk covered with varnish is introduced. The height of the condensator was about 6 feet. On introducing two condensators into a circuit the intensity of the electric light is doubled. Such condensators are not cheap owing to the great quantity of silk wanted, and thus the application of this apparatus is limited. The lecturer believes the new system of electric lighting devised by M. Rapiéff to be a serious opponent of Jablochkoff's process. The chief advantage of the new system is that the luminating point does not change its position, and therefore this system is more suitable for the projection of the electric light at a distance. This advantage will give increase to the use of the electric light for military purposes.

M. Gregorieff, of the Petrovsky Agricultural Academy of Moscow, has made some interesting experiments concerning the quality of milk sold in various places in the city of Moscow. In large towns of Europe the falsification of milk has given rise to a great number of investigations, and this question was discussed in detail. It appears that in Moscow the milk sellers mix water very moderately in a few cases, and have altogether little knowledge about the "chemicals," viz., chalk, starch, flour, &c. In all the samples analysed, no such "chemicals" were present. The 64 samples of milk were taken from the following places in Moscow:—Samples A, from peasants living in the vicinity of the town (17); samples B, milk from the town cows (6); samples C, from small grocers' shops (14); samples D, from milk shops (22); samples E, milk of the Academical farm.

The following are the average results of the analyses of these milks:—

	A.	B.	C. Samples.	D.	E.
Water	88.13	88.08	89.16	87.48	87.53
Dry substance..	11.87	11.92	10.84	12.52	12.47
Fat	2.76	2.39	1.55	3.13	4.10
Mineral substance ..	0.87	0.79	0.71	0.69	0.67

As compared with an average analysis of normal milks from healthy cows, the first four samples cannot be called bad specimens. For comparison the following analysis (average) may be mentioned:—

Water	87.25
Dry substance ..	12.75
Fat	3.50
Mineral substance ..	0.75

These results were obtained by Fleischmann (Molkereiwesen, 1876). The milk of the Academical Farm (sample E) is certainly a very high and good specimen; such milk will never be found in the hands of the sellers.

S. KERN, M.E.

INSTITUTE OF CHEMISTRY OF GREAT
BRITAIN AND IRELAND.

An Examination in Practical Chemistry in connection with the Institute of Chemistry will be held during the last week of January next. Examiner, Dr. W. J. Russell, F.R.S. Candidates can obtain further information on application to the Secretary, Mr. Charles E. Groves, Somerset House Terrace, London W.C.

The Authors of "A Practical Treatise on the
Manufacture of

SULPHURIC ACID."

with nearly 100 new illustrations (Sampson, Low, and Co., 188, Fleet Street, E.C.) are prepared to furnish plans and advice and superintend the erection of plant in all parts of the world.—Address, L. and L., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO IRONMASTERS AND OTHERS.

An Associate of the Royal School of Mines, who has been Chemist for the last eight and a half years at Iron Works in Northamptonshire, wishes for a re-engagement as Manager or Chemist. Is well acquainted with the working, analysis, and smelting of Northamptonshire ironstone, and has been accustomed to teach analysis and assaying to pupils in the laboratory.—Address, "Chemist," Midland Road, Wellingborough.

Situation wanted by a Competent Analyst as Assistant or Principal. Good teacher. Apply, Public Analyst, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, a Foreman in Superphosphate Works. Capable of undertaking the making of Sulphuric Acid and mixing. First class references required. He must be a married man. Apply to Edward Toyne, Saxilby, Lincoln.

THE
QUARTERLY JOURNAL OF SCIENCE.

Edited by WILLIAM CROOKES, F.R.S., &c.

Now ready, No. LXI., January, 1879, price 5s.

CONTENTS.

ESTIMATION OF CYANOGEN IN SODA-LYES.

By FRED. HURTER Ph.D., &c.

THE cyanogen compounds which occur in soda-lyes are the following:—

Sodium ferrocyanide,
Sodium sulphocyanide,
Sodium cyanate.

Though in crude soda (black-ash) the cyanogen is contained as cyanides, the soda-lye obtained therefrom contains no cyanides. During the lixiviation the cyanides are transformed into ferrocyanides, and all the vat-liquors I have yet investigated contained more iron in solution than the cyanogen would account for. If, however, sodium cyanide is present at all it is readily converted into ferrocyanide by boiling the liquid with freshly precipitated protoxide of iron.

The most important of the cyanogen compounds to the manufacturer is the ferrocyanide, since this salt brings into the solution a sufficient amount of iron to colour the finished product slightly brown.

The sulphocyanide and the cyanate are practically of no importance, as they yield colourless products of decomposition during the further treatment of the soda. The chief problem to the chemists of alkali works, consists, therefore, in the rapid estimation of the ferrocyanides. The following method will be found exceedingly rapid, and sufficiently accurate for solutions containing not more than a grms. of sodium cyanide per litre.

When soluble ferricyanides are mixed with salts of copper a yellow precipitate of ferricyanide of copper is formed. If a proto-salt of iron is added afterwards a blue precipitate will be formed so long as any ferricyanide exists still in solution. As soon, however, as all the ferricyanide has been precipitated, the addition of a ferrous salt produces no longer a blue colour, but reacts upon the ferricyanide of copper, reducing it to ferrocyanide of similar composition to that obtained on adding to an excess of ferrocyanide of potassium a copper solution gradually. The reaction is represented by the following equation:—

This reaction suggests an indirect estimation of the cyanogen compounds by measuring the amount of protoxide of iron which can be transformed into peroxide. It is not, however, this which forms the principle of the method now to be described, and which makes use of the above reaction simply as indicator.

100 c.c. of the strong soda-lye are oxidised by means of chlorine, hypochlorite of soda, or, simpler, bleaching-powder solution, until the whole of the sulphides, &c., are converted into sulphates, and the ferrocyanide into ferricyanide; the solution, after being acidified and freed as much as possible from excess of chlorine by warming and agitating, is ready for titrating.

On a porcelain slab sprinkle a few drops of a dilute solution of ferrous sulphate (1 part of ferrous sulphate to 100 parts of water). Add now to the solution to be analysed a twentieth normal copper solution from a burette until a drop of the solution, on being brought in contact with a drop of ferrous sulphate solution, no longer gives a blue colour, but yields the pure purple colour of cupric ferrocyanide. The copper solution is prepared by dissolving pure metallic copper in as little nitric acid as possible, and diluting with distilled water. (3.17 grms. of

copper are diluted to 1 litre. 1 c.c. = 0.001313 grm. Na_4FeCy_6 .)

This process, from its extreme simplicity, will commend itself for approximate comparative examinations.

The ferrocyanide of copper, if present in larger quantities than those indicated above, hides too much the blue colour of the Prussian blue, and must be separated before applying the ferrous sulphate. Moreover, in concentrated solutions, the precipitate of ferricyanide of copper contains more cyanogen per atom of copper than the formula $\text{Cu}_2\text{Fe}_2\text{Cy}_{12}$ requires. In dilute solutions, however, the amount of copper solution required is such as to correspond sufficiently close with the formula above stated; and considering that not one of the many other compounds contained in soda-lyes interferes with this process of estimating the cyanogen, it will rival in accuracy any other volumetric process devised for this purpose.

If it is apprehended that the solution under examination contains cyanide of sodium beside ferrocyanides, it must first be boiled with a small quantity of ferrous oxide, produced by adding a little ferrous sulphate. The solution is then oxidised, acidified, and is ready for testing.

The sulphocyanide is present in traces only. It can approximately be estimated by acidifying the solution under examination, adding some chloride of zinc to precipitate ferrocyanide of zinc. The solution is then filtered, and the filtrate coloured by means of ferric chloride. In a second vessel an equal quantity of ferric chloride, diluted to the bulk of the solution under examination, is coloured by means of a solution of sulphocyanide of potassium of known strength, until the tint of both solutions is alike. The amount of sulphocyanide thus consumed is in some degree a measure of the sulphocyanide contained in the lye, but this is usually so small that its estimation is of no practical utility.

Laboratory of Messrs. Gaskell, Deacon, and Co.,
Widnes, January, 1879.

ON THE COMBINATIONS OF AURIN WITH MINERAL ACIDS.*

By R. S. DALE, B.A., and C. SCHORLEMMER, F.R.S.

In our last communication† we stated that by the action of acetyl chloride on aurin we obtained a colourless crystalline compound, which we intended to examine more closely. We have since found that this body is identical with a compound which Gräbe and Caro‡ obtained by the direct union of aurin and acetic anhydride and having the formula $\text{C}_{19}\text{H}_{14}\text{O}_3 + \text{C}_4\text{H}_6\text{O}_3$.

We also mentioned that the purification of this substance was found to be beset with several difficulties. The cause of this was found out after some trouble, but at the same time we were rewarded by the discovery of a series of remarkable bodies, consisting of combinations of aurin with mineral acids.

These salts, as we may call them, are beautiful bodies, crystallising exceedingly well, and although some of them are decomposed by water, they are very stable in dry air. To their discovery we were led by the following observations.

On heating aurin with glacial acetic acid and acetyl chloride, the crystals lose at once their steel-blue lustre and assume a pale red colour. To obtain the compound thus formed in a pure state, acetyl chloride was added to a saturated solution of aurin in acetic acid. The liquid assumed at once a much lighter colour, and soon pale red needle-shaped crystals having a diamond lustre separated out. On re-crystallising these repeatedly from alcohol

* Read before the Manchester Literary and Philosophical Society December 20, 1878.

† *Proc. Lit. and Phil. Soc.*, 1878, 141, and *CHEM. NEWS*, vol. xxxviii., p. 34.
‡ *Ber. Deutsch. Chem. Gesell.*, xl., 1, 122.

we obtained oblong six-sided plates, which, as analysis showed, were pure aurin.

On treating the original crystals with water they become dull and brownish red, the solution containing acetic and hydrochloric acids. It therefore seemed not improbable that an additive product of aurin and acetyl chloride had been formed, containing, however, also acetic acid, as a superficial examination showed that the liquid contained, to one molecule of hydrochloric acid, much more than one molecule of acetic acid. We therefore tried to obtain an analogous benzoyl compound, and to determine in it, after decomposition with water, the relative quantities of hydrochloric and benzoic acids.

On adding benzoyl chloride to a hot solution of aurin in acetic acid, similar crystals as before were obtained, which, after being dried on filter-paper in dry air, were decomposed by water, but only hydrochloric and acetic acid went into solution, and on heating the product with water or alkalis but a mere trace of benzoic acid could be detected.

These facts, coupled with the observation that the bright red needles which, as we stated in our former paper, are formed by crystallising aurin from hot aqueous hydrochloric acid, retain the latter obstinately, led us to the conclusion that this acid forms a definite compound with aurin.

Such a body could be formed under the above conditions, as our glacial acetic acid contained a little water. Moreover, Mr. Charles Lowe had informed us that the splendid specimen of aurin which he exhibited at Paris was obtained in the following way:—The crude but crystalline aurin, which is obtained by heating pure phenol with sulphuric and oxalic acids, was dissolved in alcohol and some strong hydrochloric acid added, by which a crystalline precipitate was formed, crystallising from hot acetic acid in beautiful red, glistening, flat needles. He was kind enough to give us a sample, and on examining it we found that water acted upon it in the same way as on our crystals.

In order to prepare a pure compound for analysis, a hot solution of aurin in acetic acid was saturated with hydrochloric acid gas; the colour of the liquid changed into a light yellowish red, and soon the compound separated out in glistening needles, which, even when perfectly dry, smell strongly of acetic acid. When exposed to the air they soon assume a steel-blue lustre, and gradually crumble into a reddish brown crystalline powder. The same properties are shown by the crystals obtained from acetyl chloride and those obtained from Mr. Lowe. When heated to 110° in a current of dry air they gradually lose all the acetic acid, which plays the part of water of crystallisation, and assume a dull red colour.

On passing hydrochloric acid gas into an alcoholic solution of aurin, similar but smaller needles are formed, containing alcohol, which is given off at 100° . The dull red residue can, like the preceding one, be heated to 100° in a current of dry air without losing hydrochloric acid, which only begins to escape at 200° .

Analysis of these compounds showed that the dried substance consists of $C_{19}H_{14}O_3 \cdot HCl$, while the crystals obtained from an acetic acid solution have the composition $C_{19}H_{14}O_3 \cdot HCl + 2C_2H_4O_2$, and those from alcohol $2C_{19}H_{14}O_3 \cdot HCl + 3C_2H_6O$.

When sulphuric acid is added to a hot alcoholic solution of aurin, small red needles are formed on cooling, which consist of $(C_{19}H_{14}O_3)_2SO_3H_2 + \text{alcohol}$. Under the same conditions an acetic acid solution yields fine prismatic crystals or flat, very glistening needles, which are an acid sulphate, its formula being $C_{19}H_{14}O_3 \cdot SO_4H_2 + \text{acetic acid}$.

We have also prepared a nitrate which is readily formed and crystallises well, but have not analysed it yet.

In our first communication to the Chemical Society we described a compound of aurin and sulphur dioxide, which is easily obtained in bright red crystals by passing sulphur dioxide into a saturated alcoholic solution of aurin. Our former observation, that this body contains water but no alcohol, we found confirmed; on heating it decomposition

easily takes place, pure aurin being left behind, but it appears to be quite stable when exposed to the air, and even on heating it with water no sulphur dioxide is given off, but a drop of sulphuric acid added to the mixture is sufficient to evolve the gas abundantly. Aurin sulphite has the composition $(C_{19}H_{14}O_3)_2SO_3H_2 + 4H_2O$.

As we have already shown, aurin forms very characteristic compounds with the acid sulphites of the alkali metals, which, in accordance with the newly established formula of aurin, must now be written as follows:—

We have also found that rosolic acid, or the next higher homologue of aurin, forms compounds with mineral acids which crystallise well. Being, therefore, a base like aurin, we think its name ought to be altered, and, as it has only been obtained from rosanilin, propose for it the name *rosaurin*.

ON THE INFLUENCE OF CHLOROFORM ON NITRIFICATION.

By OTTO HEHNER, F.C.S., F.L.C.

NITRIFICATION, according to Schlösing, Muntz, and Warington, is prevented by chloroform.

The following experiments tend to prove that this is the case only when a relatively large amount of chloroform is employed, small quantities not only *not* preventing nitrification, but actually favouring the development of bacteria and the reduction of nitric acid into ammonia.

In a paper read before the Society of Public Analysts I have shown that on keeping ordinary drinking-water for some length of time the nitrogenous matter breaks up with the formation of ammonia, which in its turn gradually changes into nitric acid.

Attempting to arrest these changes by the addition of chloroform to polluted water, I was struck with the rapid development of bacteria in those samples which had received but small additions of chloroform, the samples becoming quite turbid and opalescent.

To $2\frac{1}{2}$ litres of a water polluted with putrid urine, yielding per 100,000 parts—

Free ammonia	0.0358
Albuminoid ammonia	0.0205

0.5 c.c. (2) and 1 c.c. (3) were added. After the lapse of three weeks sample 1 (without chloroform) showed—

Free ammonia	0.0007
Albuminoid ammonia	0.0065

Whilst (2) yielded—

Free ammonia	0.0992
Albuminoid ammonia	0.0480

And (3)—

Free ammonia	0.0109
Albuminoid ammonia	0.0659

Both (2) and (3) were very turbid when last analysed.

To samples of 8 litres each of another water, containing some putrid urine, 2 and 5 c.c. of chloroform were added. On January 18, 1878, the day on which the experiments were commenced, the samples showed—

Free ammonia	0.0239
Albuminoid ammonia	0.0430

On February 11 the sample without chloroform had changed to—

Free ammonia	0.0436
Albuminoid ammonia	0.0244

Whilst the water with 2 c.c. of chloroform contained—

Free ammonia	0.2017
Albuminoid ammonia	0.0208

And that with 5 c.c.—

Free ammonia 0.0227

Albuminoid ammonia 0.0404

The bottles containing the samples were kept freely exposed to daylight.

5 c.c. of chloroform had therefore prevented all change, whilst 2 c.c. had been quite ineffectual, the free ammonia having risen tenfold, doubtless at the expense of the nitrate contained in the water.

During the first week the albuminoid ammonia had somewhat increased in the latter sample.

Chloroform in small quantities is therefore rather a food than a poison to bacteria.

COMPOSITION OF THE GAS WHICH ISSUED FROM ONE OF THE SHAFTS OF THE ABERCARN COLLIERY.

By J. W. THOMAS.

It will be remembered by those who have read the reports of the terrible explosion which occurred at Abercarn on September 11 last, that in consequence of the coal having taken fire close to the main shaft at Abercarn and in the workings, and a direct communication between the upcast and downcast being determined by the explosive force which destroyed the parting doors, it was soon discovered that it was advisable to flood the colliery in order to quench the fire. It will be remembered, too, that the colliers who were fortunate enough to escape with their lives found their way out by the main winding shaft. The Abercarn Colliery has three shafts or pits—two downcasts and one upcast. The main downcast and upcast, which are 22 yards apart, are situated at Abercarn, and the other downcast is at Cwm Carn, a distance of a mile and a quarter in a direct line, and two miles underground from the upcast. As soon as the Abercarn portion of the workings was filled with water, the gas issuing from the coal and some of the products of combustion from the burning of the coal, and possibly more or less of the products of complete and incomplete combustion incidental to the explosion, were driven in the direction of the Cwm Carn pit, toward which the measures rise about 400 feet or a little over 2 inches per yard. After the flooding of the colliery was completed on September 16, when over 40 feet of water were in the two shafts at Abercarn—a large volume of gas, varying from 500 to 1500 cubic feet per minute, was evolved until the water was cleared out (about the middle of November) sufficiently low to admit of a current of air being drawn in the direction of the upcast shaft. On September 20th last I collected some of the gas issuing from the Cwm Carn shaft, which was covered with turf with the exception of a hole in the centre occupied by an iron pipe 11½ inches in diameter, through which the gas escaped. On both occasions the gas was collected in glass tubes previously fashioned for sealing off the ends before a blowpipe flame—a double acting syringe being employed to cause the gas to fill the tubes by displacement. The analysis of the sample of gas collected September 20 is marked No. 1. At the time of collecting it 500 cubic feet per minute were evolved, the temperature being 58° F. On October 9, I again collected gas, the composition of which is given in No. 2—about 1200 cubic feet of gas per minute were escaping at the time.

Composition of the Gas in 100 Parts.

	No. I.	No. II.
Carbonic anhydride ..	2.54	2.43
Air { Oxygen	2.73	none
Nitrogen	10.32	—
Marsh-gas	49.11	74.63
Hydride of ethyl	0.95	0.81
Nitrogen	34.35	22.13
	100.00	100.00

The composition of the hydrocarbons present, other than marsh-gas, resembled hydride of ethyl, but the analytical volumes did not agree well in No. I. On comparing No. I. gas with No. II. it is evident that the former contains a considerable proportion of nitrogen derived from atmospheric air, the oxygen of which had been used up to support the combustion of the fire-damp or the coal which was on fire. Owing to the plentiful supply of air which reached the burning coal previous to the colliery being flooded, it is possible that little if any carbonic oxide was generated, and the absence of this gas in No. I., in which it was carefully sought, seems to show that the incomplete products of the combustion of the explosive mixture (the fire-damp which gave rise to the explosion) had either in part been removed or so diluted with other gases that the carbonic oxide was present in quantity too minute to be determined in the process of analysis. The composition of No. II. is interesting. This consists doubtless of a mixture of blower-gases which found their way into the galleries through the channels and cracks in the strata, and the gases evolved from the working face or other exposed coal. The latter gases would be naturally of similar composition to those which escape under ordinary conditions of pressure and temperature from a lump of coal exposed to the atmosphere. In previous papers "On the Gases Enclosed in Coal," *Chem. Soc. Journ.*, 1875-6-7, I have pointed out on more than one occasion the curious fact that nitrogen escapes from coal in a vacuum at a proportionally quicker rate than any other gas. The flooding of the mine entirely cut off the supply of air and consequently no nitrogen could find its way into the galleries, admitting the possibility of the oxygen being used up. It is evident, therefore, that the percentage of nitrogen in No. II. is high, and that this circumstance points to the probability of its escaping from coal under ordinary conditions in the same manner as it does in a vacuum. Before No. II. sample was collected it will be seen from the analysis that all the air had been swept out of the workings by diffusion with the gases evolved from the coal, and long before the expiration of the nineteen days which elapsed between the collection of No. I. and No. II. all the products of combustion would have been removed. During the nineteen days an average of more than 1,000,000 cubic feet of gas was evolved each day, equal to the cubic contents of a large gallery or heading ½ miles in length. My thanks are due to Mr. Pond, of Abercarn, for the facilities afforded me in the collection of the gases and for his kind assistance.

The Laboratory, Cardiff, January 6, 1879.

ANALYSIS OF POPPY PETAL ASH.

By C. J. H. WARDEN, F.C.S.

ANALYSES of the organic constituents of poppy petals have been made by several chemists, but poppy petal ash has not hitherto, as far as I am aware, been examined. Before giving results of the analysis of the ash, a few remarks on the use to which poppy petals are put in the Government Opium Factories in Bengal may be interesting.

In the manufacture of opium for the China market—"Provision Opium"—it is customary to envelope the soft opium in a shell composed of poppy petals technically termed "leaves."

The petals are usually collected by noon on the third day of the flowers' expansion, and Mr. J. Scott thus describes the process:—"They clasp the petals at the base with the forefinger and thumb, gently drawing them upwards, and tightening them over the apex of the capsules, when the matured petals at once disarticulate or detach themselves. There is thus no tearing or straining of the petals, and no loss of juice from the disarticulated surfaces."

* "Manual of Opium Husbandry," by J. Scott.

The petals are then made into round "leaves" by spreading them on gently heated earthen or iron saucers, covering them with a moist cloth, and applying firm pressure by a damp pad. "Leaves" vary in diameter from 6 to 12 ins., and in thickness from 0.5 to 0.025 of an inch.

At the Patna Opium Factory 10 ozs. 94 grs. avd. of "leaves" are used for making the shell of each cake. The "leaves" are agglutinated round the opium by a 50 per cent mixture of opium in water.

Mr. Scott calculates that the annual consumption of poppy petals is upwards of 16,000 maunds (one maund equals 100 lbs. troy), to compose which the entire petals of no less than 4,710,400,000 flowers are required! During the season 1869-70 the Bengal Government spent £10,235 on leaves for the use of one factory. From the above short account of "leaves" it is evident that the poppy petal is an article of considerable commercial value.

The ash was prepared for analysis in the usual way, and was of a light grey colour, and effervesced with acids. An aqueous solution gave indications of the presence of SO_3 , P_2O_5 , Cl, and K. All the determinations were by gravimetric methods:—

100 Parts of the Ash Contained.]

IS CONTAMINATED WATER INJURIOUS FOR DOMESTIC PURPOSES?

By SERGIUS KERN, M.E., St. Petersburg.

THE St. Petersburg town council organised a committee for the discussion of the following question:—About seven miles from the town a new cemetery was opened some years ago. A small river runs from this place into the Neva, some eight miles above the town. It was found that this small river is entirely contaminated by the decomposition of the bodies. Owing to this inconvenience many propose to close the cemetery. The discussions which took place in the sitting of the committee on November 23, 1878, are rather interesting, as the sanitary improvements of the town are still considered secondary questions.

M. Borodin, Professor of Chemistry, thinks that water

containing a certain amount of putrescent substances cannot have a great influence on the health of the inhabitants of the town, and remarked that even in science this question is nearly an open one, as it has been only partly discussed. Indeed, it is a question if contaminated water, used for domestic purposes, can do any harm. The Professor remarked, also, that sometimes, for instance, in consuming various cheeses we introduce at one time a quantity of putrescent matter into the stomach, which would not be detected in the annual amount of water consumed, containing a large quantity of organic matters. The analyses of the Neva water (by Professor Trapp) show that it cannot be called bad water:—

In 1 Cube Metre.

Inorganic matter	32.25 grms.
Organic matter	23.00 "
CaCO_3	15.25 "
MgCO_3	7.40 "
NaCl	1.60 "
Na_2SO_4	2.40 "
K_2SO_4	1.30 "
FeCO_3	1.20 "
Al_2Cl_6	2.60 "
SiO_2	0.50 "

M. Bertenson could not agree with the Professor. He remarked that oxygen is very important in water, and certainly the more organic matter is present in the water the less it contains of free oxygen.

The committee decided to inspect the cemetery, and take some water for analysis from the small river, and then agreed to inspect also one of the bodies which was buried the first on this ground. The conclusions of the committee will be of some interest, as there is not much agreement between the members concerning the question discussed.

THE URIC ACID GROUP.

By SAMUEL E. PHILLIPS.

As Mr. P. T. Main has advanced some new views of urea, uric acid, and their derivatives, it may interest some students of chemical philosophy if I give the substance of a paper read before the British Association of 1877, "On the Principle of Uric Acid Genesis."

"As the vast and complex researches of Liebig, Strecker, Baeyer, and others have now culminated in the studies of M. Grimaux, it is thought to be high time to trace herein the plain indications of law, order, and symmetry in lieu of empirical confusion." The author refers to a paper on the constitution of uric acid (CHEM. NEWS, vol. xxxii., p. 209), and now maintains that a clear view of the chemical laws involved in -2HO , under varied conditions, will supply the key to unravel the endless empirical confusion.

Starting with eight acids, it is maintained that under the combined influence of heat, time, and pressure that all these, and some others, act similarly upon urea, and condense with successive eliminations of -2HO , in proportion to the strength or duration of the applied conditions:—

Hydromellitic acid (?)	$\text{C}_4\text{H}_2\text{O}_2\text{O} \cdot \text{HO}$
Glycollic acid	$\text{C}_4\text{H}_3\text{O}_4\text{O} \cdot \text{HO}$
Glyoxalic acid	$\text{C}_4\text{H}_1\text{O}_4\text{O} \cdot \text{HO}$
Glyoxylic acid	$\text{C}_4\text{H}_3\text{O}_6\text{O} \cdot \text{HO}$
Unknown acid	$\text{C}_6\text{H}_7\text{O}_2\text{O} \cdot \text{HO}$
Pyruvic acid	$\text{C}_6\text{H}_3\text{O}_4\text{O} \cdot \text{HO}$
Malonic acid	$\text{C}_6\text{H}_1\text{O}_4\text{O} \cdot 3\text{HO}$
Tartronic acid	$\text{C}_6\text{H}_7\text{O}_6\text{O} \cdot 3\text{HO}$

That with these, eight ureide series may be projected, embracing very much that is already known, and presenting

some blanks, which may easily be attained in the future, and that these eight series may be thus epitomised, assuming 1 equivalent of acid in each case:—

- + Urea $-2\text{HO} = (\text{CO})_2\text{RH}_3\text{N}_2 = \text{the R urea (a)}$
 $-4\text{HO} = \text{CyRH}_3\text{N} = \text{the cyanamid (b)}$
 +2 Urea $-2\text{HO} = (\text{CO})_4\text{RH}_7\text{N}_4 = \text{the di-urea (c)}$
 $-4\text{HO} = (\text{CO})_2\text{CyRH}_5\text{N}_3 = \text{the pseudo-uric acid (d)}$
 $-6\text{HO} = \text{Cy}_2\text{RH}_3\text{N}_2 = \text{the ultimate (e)}$

It is remarked that these uric acid *ultimates* are not strictly such, and the two extensions of variety are excluded from the brief terms of the paper:—First, certain obscure cases where these radicals are affected by reaction with ammonia -2HO , as in hydrazulmoxin and hydrazulmin; secondly, the more complex forms of ureide condensation obtained by M. Grimaux, which all, nevertheless, prove to be grand illustrations of the same definite laws.

It follows that all the (a's) are normal ureas, though often associated with confused names in their empirical discovery; that all the (b's) are R cyanamids, though not at all recognised as such, and some of them are called ureas; that the ureides or di-ureas have three stages ending in uric acid and its other analogues; that the law of elimination has three aspects:—

1. When hydrates condense into each other, or into an ammonium, as thus—

2. When successive elements of ammonia are super-added to the condensation, each step is attended with an additional -2HO by derivation from the radical when no hydrate subsists. A wonderful regularity may be traced in the glucuride researches of M. Schiff, by which for illustration—

And a recent research of M. Ladenburg's, where hydrates are "condensed into toluylene diamine, affords a striking illustration, the more so, as given like the former, on empirical and independent grounds.

"3. When ureas condense into ureides, the tendency, after eliminating -2HO for each equivalent of acid or hydrate, is for each $(\text{CO})_2$ to change into cyanogen with elimination of 2HO , as typified in the well known case—

I am much pleased to find that I am not alone in entertaining the cyanamid character of uric acid; but the idea of including urea in the same category, as a derivative of uric acid, is certainly a confused and illegitimate sketch of hypothesis.

The ammoniacal character of urea is established beyond question; its amide dedoublements and their basic characters admit of no other explanation.

M. Dreschel, in obtaining several varied cyanamids, notates one as "the hydrochlorides." It is therefore clear that he might have obtained the hydrate. Besides, hydrates of dicyanamid and others are known, but surely no one expects to find them ureal.

Mr. Main falls into a mistake, which his notations ought to have corrected; but, alas! they are only fitted to mislead. Allantoin is not a derivative of "glyoxylic acid," as may be seen thus:—

(b) As urea -2HO becomes cyanamid, so glyoxalyl urea -2HO becomes glyoxalyl cyanamid.

(c) Is the hypothetical first stage of the di reaction.

(d) The second stage is *allantoin*, and the formula of production is precisely that given by the discoverer, M. Grimaux. It also corresponds with M. Grimaux's *Pyruvil* in the pyruvic series, or with my pseudo-uric acid in the tartronic series.

(e) Is the ultimate mis-called "mycomelic acid" and the perfect analogue of uric acid.

One word more as to the *bizarre* character of these misleading notations.

The discoverer of "melid acetic acid" thought it was an aceto body, and that it was an acid, and hence the terminal (COOH) so fashionably characteristic of acid types! Of course the pretence is that these structural or graphic portraits are intended to delineate certain features of genetic or analytic behaviour in the compounds. The plain fact is, however, that it is a mischievous device of wanton hypothesis, and hence our exposure of the true nature of that body, as containing no acetic acid in its genesis, and no acid behaviour in its derivatives. It is a substituted *mellamine* base! (See CHEMICAL NEWS, vol. xxxiv., p. 13.)

When M. Grimaux speaks of glyoxylic acid he means glyoxalic acid, and his notations correspond with his remarkable synthesis of allantoin: but Mr. Main, rightly estimating the total elements of glyoxylic acid, gives allanturic acid as one of its derivatives, which is a double mistake. First, as a matter of chemical fact; and, secondly, as a matter of notational display.

Allanturic acid is "glyoxalyl urea." Why, then, justify its early misnomer by an *acid* notation ending in (COOH)

Glyoxylic acid—

Allanturic acid—

And why notate it with cyanogen as a constituent?

Under the derivatives of tartronic acid we have—

Dialuric acid—

Violuric acid—

(a) is tartronic urea, $(\text{CO})_2\text{C}_6\text{H}_7\text{O}_6\text{H}_3\text{N}_2$. Both (a) and (b) are given with the acid terminations to correspond with tartronic acid; but it is quite overlooked that (b) belongs to another acid series, for it is known to be a "malonyl urea."

How, then, does it happen that so many amides should be called acids? The answer is plain, and the parentage is clearly traceable to a mistaken hypothesis of the early discoverers, which is grossly perpetuated to this day. They noticed among these bodies a tendency to combine with or to assimilate metal ingredients, and the notion was that the relation subsisting was that of acid and base.

It is, of course, familiar that many hydrocarbons have a tendency which is notably typified in acetylen; and we now find that the same tendency is frequently evinced among amides; but the wonder is that modern chemists should be so slow in establishing a just discrimination.

Were we to imitate Mr. Main's ureal hypothesis, and contend that ammonia was an acid, and that the amides of Zn, Cu, or K were its basic salts, the idea would necessarily be scouted; but the same principle is largely and widely indulged in throughout the modern types of organic chemistry; and we constantly read of amido acids, and see their terminal (COOH) graphically displayed, while the context in so many cases reveals the fact of their *basic* characters, as seen in their "hydrochlorides," their sulphates, nitrates, and other salts.

I care not to follow Mr. Main when he seeks to paint the lily, and to improve his *bizarre* notations by atomicity equations and "more symmetrical" portraits of the atomic dispositions. But the body selected for all this display is wisely chosen from the least understood of chemical compounds, viz., the amorphous substance called "hydrazulmin."

It may or may not be a definite chemical body; but as I have done my best, in a known and legitimate way, to arrive at some faint *a priori* understanding of its genesis and relations in a yet unpublished "Study of Ureide Derivatives," it may be well to compare notes as to our methods of investigation. One is playing with shillies, and can place them in any position, only controlled by certain laws of the game, such as the atomicity rules, &c. The other is rather a student of the actual chemical forces involved, and has comparatively a very limited number of pieces. He can only place on the board definite or well known radicals, and these only in certain limited modes of relationship, while from an infinitude of "residues" he is utterly debarred.

With one it is an easy matter to build up on paper a melid-acetic acid, or an allanturic acid, with wrong materials; with the other these feats are simply impossible. One is so confidently assured that he can open out the condensed types to graphically exhibit the internal play of atomicities, and go yet further in the Frankland school to "more symmetrical" pictures. The other has to retire in all humility, simply confessing inability to either execute or understand such works of art.

"We have referred to the uric acid analogues as *ultimates*. That term, however, admits of some qualification, because by another mode of reaction it is possible to reduce the radicals of the varied acids, and in that respect to realise more ultimate compounds.

- "Mycomic acid," $Cy_2C_4H_2O_4H_3N_2(a)$
 $(a) + H_3N - 2HO$, hydrazulmoxin,
 $Cy_2C_4H_2O_4H_2(NH_2)_2N_2(b)$
 $(b) + H_3N - 2HO$, hydrazulmin,
 $Cy_2C_4H_2OH(NH_2)_2N_2(c)$

It only remains to notice that this hydrazulmoxin is identical or isomeric with Mr. Main's "azulmic acid."

That in each of these stages of reaction one equivalent of ammonia is added is a chemical fact beyond question; and that each stage implies a theoretical tendency to $-2HO$ is a principle I have tried hard to exemplify, and need not here repeat the grounds, while gladly referring to the actual facts of analysis in confirmation.

PROCEEDINGS OF SOCIETIES.

NEWCASTLE CHEMICAL SOCIETY.

General Meeting, November 28, 1872.

Mr. R. C. CLAPHAM, President, in the Chair.

THE minutes of the previous meeting were read and confirmed.

The following were elected members:—Mr. Walter Weldon, Dr. Bernard Mohr, Mr. John Watson, Mr. Thos. Campbell, Mr. John Hope, jun., Prof. R. W. Atkinson, Mr. Mayfield, Mr. J. W. White, Dr. H. E. Armstrong, Mr. T. Crawford, Mr. W. G. Strype.

The following name was read for the first time:—Mr. John Cliff, Runcorn.

THE PRESIDENT—Our first business, gentlemen, is to proceed to the discussion on Mr. Pattinson's paper, "On the Quality of the Small Coal used on the Tyne." It is a very valuable paper, especially as regards the amount of sulphur contained in the ash. I do not remember having before seen results set forth to show both the vola-

tile sulphur and the sulphur contained in the ash. Perhaps it might be interesting to the members if Mr. Pattinson would explain how the amounts of these latter are determined.

MR. PATTINSON—It is very quickly done. The total sulphur is determined in the usual way, by oxidation; then the amount remaining in the ash of the coal is determined, and the difference of these two amounts gives the volatile sulphur. The sulphur in the ash is retained by virtue of the lime which the ash contains, which probably existed originally as carbonate. I may perhaps mention here the method used to determine the total sulphur in the coals. The old method, by heating with strong nitric acid and evaporating to dryness, is very incorrect, never yielding more than a fraction of the sulphur really contained in the coal. The method by deflagration with nitre and salt is very correct when carefully done, but it requires great care, both in the deflagration and in the subsequent precipitation of the sulphur as barium sulphate. The method now used, however, is very much simpler than any of the old ones: a weighed quantity of the coal or coke (about 20 grains) is mixed with one and a half times its weight of slacked lime, moistened slightly with water, and then heated in a muffle at a red-heat. The carbon burns off, and the sulphur is converted into calcic sulphate, which is then dissolved in hydrochloric acid, and the sulphuric acid precipitated in the usual way.

MR. H. L. PATTINSON—What is the reason that the method of treating with nitric acid is unsatisfactory?

MR. J. PATTINSON—Probably a portion of the pyrites is covered and protected by the coal, even when it is very finely pulverised.

THE PRESIDENT—If no member has any more remarks to make we will proceed to the discussion on Mr. Dunn's paper, "On Indicators in Alkalimetry." I do not know if Mr. Dunn has anything further to add on the subject of his paper.

MR. DUNN—I have not done anything more in the matter since the paper was read. I may just mention, however, that aurin does not keep quite so long as litmus. It will, however, keep for two or three months without alteration, and the preparation of the solution is so easy that it can be made afresh every two or three months with very little trouble.

THE PRESIDENT, in calling on Mr. Cookson to read his paper, "On Rozan's Process for Desilvering Lead," said, I had the pleasure of going down to Messrs. Cookson's works, at Willington, a few weeks ago, and I think I have not for a long time been in any works which were more interesting, both from a chemical and a mechanical point of view. The handling of large quantities of lead is done almost entirely by hydraulic machinery, which I have no doubt saves a large amount of money formerly spent in wages for hand labour. The paper to come before us to-night is one of very great interest, and perhaps, if we say anything about it now, it must be to express a kind of regret that a patent is likely to come into operation which may do away with the classical process of Mr. H. L. Pattinson—a process for which the North of England has long been justly celebrated.

"On Rozan's Process for Desilvering Lead," by Mr. COOKSON.—In attempting to describe the leading features of the Rozan system of desilvering, I must ask you to bear in mind that in principle it is in most respects identical with the well-known process of the late Mr. H. L. Pattinson, always excepting that in the former case cranes and steam supersede the more expensive system of manual labour employed by Mr. Pattinson. In both cases, however, the whole working depends on the fact that as melted lead cools the first-forming crystals contain less silver than the portion remaining liquid, and that in the usual way of working by thirds this exists to the extent that when two-thirds of a given quantity is in crystals and one-third liquid, the two-thirds will actually contain only half the quantity of silver that the one-third or lesser quantity does. In the Rozan system steam is

used with a double purpose, one of which is mechanical and the other chemical. The mechanical effect is to boil up and violently stir the melted lead, thus preventing any setting on the surface; and this boiling of the steam through the lead as it cools causes a regular crystallisation, and an easy and perfect separation of the liquid from the crystals when the proper stage is reached. The chemical effect is due to the oxidising action of the steam on the antimony, copper, iron, arsenic, and other extraneous metals, which, being converted into oxides, are either skimmed off or carried away with the escaping steam, and afterwards allowed to settle in the condensers. This chemical action fulfils so good a purpose that the Spanish rich silver leads are desilverised without any previous calcination, and an unusually pure market lead is produced from them. Even in the case of Greek lead only a partial calcination is required, as experience shows that a portion of antimony, equal to about $\frac{1}{4}$ per cent, existing in the original silver lead, is an advantage, inasmuch as this small quantity of antimony has a remarkable effect in reducing the quantity of lead oxides formed. Without absolute proof it may be premature to speak of any chemical action, as it is possible the whole of the oxidation is due to the mechanical exposure of the molten impure lead to the influence of the atmosphere, assisted by the air carried into the pot by the steam; but I am strongly of opinion that a chemical action actually takes place. The leads most suitable for the steam process are of a similar class to the already-mentioned Spanish rich silver leads, containing from $\frac{1}{4}$ to $\frac{1}{2}$ per cent of foreign metals, of which antimony generally constitutes fully two-thirds of the quantity. In the old Pattinson process those extraneous metals are eliminated as far as possible by a previous calcination, the charges sometimes requiring forty-eight hours in the calcining furnace in order to fit them for the pots. In the Rozan system, however, this calcination is dispensed with, and the lead as it comes out of the smelting furnaces is used direct by the desilverising apparatuses.

Having described the working of the plant, I will put before you as shortly as I can the advantages and defects of the Rozan as compared to the Pattinson system as carried out in our works for a great number of years. The advantages the Rozan system possesses are—

1. The entire saving of the cost of calcining all ordinarily hard leads, and in the case of extra hard leads, such as Greek lead, a very large saving.
2. A cost for labour not exceeding one-fifth.
3. A cost for fuel of about two-fifths.
4. A saving of one-third in the oxides produced, which advantage any lead manufacturer will fully appreciate.

Its defects are—

1. A large capital outlay.
2. A constant expense in repairs and renewals.

The repairs are only a small matter, but until lately the cost of renewal of pots was a very serious and heavy item: it is one which by observation and care we have been able very considerably to reduce. In 1876 pots cost us over 3s. per ton of market lead; in 1877 it came to 2s. 2d.; and this year, so far, the cost has been further reduced to 1s. 4d. per ton.

On the whole, the advantages are very considerably greater than the defects of the Rozan system; and I can confidently assert that our firm has every reason to be satisfied with having adopted it.

The following is a table showing silver assays of twelve crystallisings taken from an average of 350 operations:—

Ounces per ton of lead.

570	315	202	112½	62	33½	19½	10	5	2½	1½	14 dwts.
-----	-----	-----	------	----	-----	-----	----	---	----	----	----------

The PRESIDENT—Would any member like to ask Mr. Cookson any questions about the paper? Mr. Morrison has referred to condensation, and it struck me that that was a point which, at the present meeting, Mr. Cookson

might give a little more account of. When I saw Mr. Cookson's works the condensation appeared very perfect and free from escape.

Mr. COOKSON—It is not a point of much importance whether the condensers are air-tight or not, because we have a draught at the far end, so that there is always an inward suction. In practice we find that in the last chamber there is little or no settling. I have sometimes opened the door and gone in, but could never observe anything except steam in the state of fog or cloud. The oxides of antimony and copper are partly skimmed off the melted lead as dross, and partly condensed as fume in the chambers. The fume near the furnaces contains a larger quantity of these oxides, and as it gets further from the furnace it approaches more and more nearly in composition to pure oxide of lead, thus confirming an old dictum of lead-smelters, that oxide of lead is more difficult to condense than the oxides of the accompanying metals. One thing I did not mention, which has indeed nothing to do with the subject of the paper, but is simply a mechanical arrangement—our system of cranes is very perfect. From the time when the crude lead enters our works to the time when it makes its exit as "market lead" it is hardly ever touched by hand, but lifted from place to place entirely by hydraulic cranes, which costs very much less than if it were lifted by hand.

Mr. GLOVER—In blowing the steam through is there any chemical decomposition of the steam, or is the action simply mechanical? Are the copper and antimony oxidised by the steam, and the oxides volatilised, or carried off mechanically?

Mr. PATTINSON—To a chemist the most interesting point in the process is that which has just been mentioned by Mr. Glover. I am inclined to think that at such a temperature the copper would not be volatilised. Could Mr. Cookson tell us the composition of the fume condensed near the crystallising pot? I think that as the oxides of copper and antimony accumulate on the top, they are most likely to be mechanically carried away to the condensers. The question is, is the steam decomposed, is hydrogen produced, or is the oxidation due to the atmosphere?

Mr. COOKSON—I think it is due principally to the free oxygen which is always contained in small quantity in the steam, and that the oxides are then carried away by a purely mechanical action.

Mr. B. S. PROCTOR—Have you ever had any trace of hydrogen?

Mr. COOKSON—I have put my nose into the condensers, thinking that if hydrogen were produced there would be a certain quantity of arseniuretted hydrogen formed, but I have never smelt any. There is a trace of sulphur found in the condensers, but I never smelt any sulphuretted hydrogen.

Mr. H. L. PATTINSON—Have you ever tried air instead of steam?

Mr. COOKSON—It is included in the patent, but it increases the quantity of oxide of lead formed very greatly.

Mr. GIBB said, it appeared to him that the action of the steam was purely mechanical, not chemical, and that the process was merely the Pattinson process with improved mechanical arrangements.

The PRESIDENT wished to remind Mr. Gibb that most of his objections had been already answered by Mr. Cookson in the paper itself.

Mr. COOKSON—I so far agree with Mr. Gibb that I often call the process "Mechanical Pattinsonisation." The steam may perhaps be described as a vehicle for conveying the oxygen of the air in limited quantity to the lead.

Mr. PATTINSON—Or a valuable means of getting the mechanical effect of air with a smaller proportion of oxygen.

Mr. MORRISON—The steam protects the lead?

Mr. COOKSON—No; for if we work soft leads we find, with all our care, that the quantity of oxides produced is largely increased.

The PRESIDENT—I will remind the members at this stage that Mr. Cookson's paper will come on for discussion at another meeting; meantime I propose a very cordial vote of thanks to Mr. Cookson. The description which he has given is very interesting, and we are all much indebted to him for such an able paper on this important question.

The motion on being seconded was carried unanimously.

NOTICES OF BOOKS.

Fourth Annual Report of the Commissioner of the Imperial Mint, Osaka, Japan. Hiogo: Hiogo News Office.

This report contains nothing of special scientific interest. It appears that the foreign staff of the Japanese mint now consists of two persons only, the chemist, Mr. W. Gowland, F.C.S., and the engineer, M. R. MacLagan, M.I.M.E., all the other posts being now filled by natives. The sanitary condition of the Mint department does not seem satisfactory; 411 cases of illness and 11 deaths out of a total of 602 men in their best years are remarkable, especially as none of the deaths were due to accidents. How much of this is due to the climate and how much to the nature of the employment cannot be known, especially as we can find no mention of the number of men in each department.

The Magic Lantern Manual. By W. J. CHADBURN. With 100 Illustrations. London: Warne and Co., 1878.

POOR Artemus Ward used to call himself a "jokist," so Mr. Chadburn takes liberties with Her Majesty's English and calls himself a "Lanternist." Whether he will succeed in adding a new word to the dictionary or not we cannot venture to prophesy, but in any case he has presented his brother "lanternists" with a capital little book on the magic lantern. He first of all describes the ordinary old fashioned oil lantern and its objectives, and then proceeds to give us an account of the Sciopticon, an American invention, which ranks half way between the old fashioned instrument and the oxyhydrogen and electric lanterns. The pyrohydrogen and magnesium lanterns are also described, as well as all the accessory instruments connected with them. Clear directions are also given for the preparation of the slides, both by hand and by photography, whether by the silver or carbon process. The part, however, which will most interest our readers is that on scientific projections. For exhibiting diagrams, optical effects, the decomposition of water, crystallisation, &c., Mr. Chadburn tells us that the Sciopticon will serve every ordinary purpose for class demonstration. This is a fact that is evidently but little known to science teachers, who always look on lantern demonstration as involving endless trouble and an enormous outlay. We cordially recommend Mr. Chadburn's little book to all science teachers and lecturers.

The Unity of Matter: A Hypothesis. (Die Einheit des Stoffes: Eine Hypothese). Von A. WALDNER. Zürich: Zürcher and Furrer.

THE author of this little pamphlet tells us in his preface that the hypothesis in question is the result of an arithmetical examination of the relations existing between the atomic weights of the so-called chemical elements. He undertook this investigation in June last (1878), but did not make his results public, as no facts were known to prove that these elements were capable of further decomposition. The recent researches of Mr. Norman Lockyer and his experiments on the transformation of the metals have induced him to publish his hypothesis, which they seem to confirm. He considers it possible that the

formulæ given below (in thesis 10) may be capable of still further simplification.

We give an abstract of the author's theses:—

1. All have arisen out of the so-called cosmic ether, the one primitive matter which fills infinite space.
2. This primitive matter, whose motions make themselves known by the phenomena of light, heat, electricity, and magnetism is not infinitely divisible.
3. The portion of the original matter, which after continued division resists all further comminution, is the primary atom.
4. All primary atoms have identical (regular) form and equally great mass (weight), and are amongst themselves perfectly congruent.
5. The cosmic ether, the initial state of all nascent bodies, is formed of primary atoms lying beside of each other without definite law.
6. In these primary atoms there inheres a power or tendency to combine with each other.
7. By these combinations of the primary atoms there arise molecules of new bodies different from the primary matter.
8. The combinations of the primary atoms take place according to the following law:—

$$\begin{array}{lll} (1.) & 2^1 & 2^2 & 2^3 \\ (2.) & 3^1 & 3^2 & 3^3 \end{array}$$

i.e., primary atoms unite together either by twos and threes, or by the third and fifth powers of two and three.

9. These six primary compounds form the basis of all known bodies, the molecules of the so-called elements being formed by combinations of such primary compounds.

10. These combinations take place simply according to the law of multiple proportions. If in series (1)—

$$2^1 = 2 = a; 2^2 = 8A; 2^3 = 32 = a$$

and in series (2)—

$$3^1 = 3 = b; 3^2 = 27 = B; 3^3 = 243 = b$$

the molecules of bodies considered as elements are formed as follows:—

$$\begin{aligned} a_2 b_2 &= 2 \times 2 + 2 \times 3 = 10 = \text{H.} \\ a_4 b_2 &= 2 \times 32 + 2 \times 3 = 70 = \text{Li.} \\ a_2 b_{10} &= 2 \times 32 + 10 \times 3 = 94 = \text{Be.} \\ a_1 b_4 &= 1 \times 32 + 4 \times 27 = 140 = \text{N.} \quad \&c. \end{aligned}$$

11. If the mass (weight) of the primary atom = 1 the above numbers show not merely the number of original atoms in the compound molecules, but also their molecular weights.

12. The conditions under which the original atoms combine together, and under which, inversely, compounds are resolved into their original matter are hitherto unknown, and are probably of a nature scarcely to be realised by the temperatures and pressures at the command of our present science and technology."

On this proposed law criticism would be obviously premature. But we do not see on what principle the author selects the factors by which a, A, and a, and b, B, and b are respectively multiplied.

CORRESPONDENCE.

A NEW TEST FOR ARSENIC.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxviii., p. 301, it appears that Mr. Otis Johnson claims the discovery that when potassium hydrate is allowed to act upon aluminium in the presence of arsenic and antimony, that AsH_3 is evolved without the evolution of SbH_3 . The above reaction is not new, having been discovered by M. Filhol, professor at Toulouse, prior to July, 1876. Prof. Filhol proposed the following, viz., if hydrogen is allowed to act

on arsenic by means of zinc or aluminium and caustic potash, and not by Zn and dilute sulphuric acid, as has always been customary in the Marsh apparatus, AsH_3 is readily evolved, but if tried with antimony compounds not the least trace of SbH_3 is observable. It is thus possible in the case of a mixture of As and Sb to disengage all the As and leave the pure Sb behind. It is also worthy of notice that when hydrogen is evolved by action of Zn, or still better Al, on potassium hydrate, if phosphorus be present, the colour of the ignited gas will be a beautiful green. The least traces of phosphorus can in this way be detected.—I am, &c.,

WILLIAM JOHNSTONE.

Analytical Laboratory, Lowther Hill,
Forest Hill, December 28, 1878.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 26, December 23, 1878.

Explosion of Deflagrating Matter.—M. Dupuy de Lôme.—The author examines into the causes of an explosion by which a M. Zédé had been severely wounded. The latter was endeavouring to find a compound which without exploding should be entirely resolved at the lowest possible temperature into gases and vapours, and which should serve as a motive power. For this purpose he employed a mixture of gun-cotton and of nitrate of ammonia. After finding the most suitable proportions he was studying in how far the speed of combustion, very slow in the open air, might be modified under increased pressure. On one occasion, when setting fire to the mixture contained in his apparatus, there occurred a violent explosion, attended by a flash of light. The tube, which had been tested up to fifty atmospheres, was shattered to pieces, and the experimentalist was seriously wounded. It would appear that a slight decrease in the orifice through which the gases escaped had changed the nature of the process from deflagration to detonation.

Magnetic Rotation of the Plane of Polarisation of Light under the Influence of the Earth.—H. Becquerel.—The author points out that the experiment described in M. Joubert's paper (*Comptes Rendus*, lxxvii., p. 984), is a reproduction of one which he had described on p. 1075 of the preceding volume.

Novel Phenomenon of Static Electricity.—M. Duter. A continuation of the controversy between the author and M. Govi.

Preparation of the Cobalto-cyanide of Potassium and of some of its Derivatives.—A. Descamps.—On pouring a cold solution of cyanide of potassium into chloride of cobalt there is formed a reddish brown precipitate of cobaltous cyanide. Care must be taken not to pass the limit of decomposition. This precipitate is kept at 0°, carefully washed in water, and then dissolved in a slight excess of cyanide of potassium at the same temperature. The liquid if diluted with alcohol deposits crystals of a deep amethyst blue. These are washed in alcohol to remove the excess of cyanide of potassium, and are then preserved in alcohol at 95°. This salt is unstable and soon turns red. If dissolved in a little water it gives a deep red solution, which yields several reactions. With acetate of lead it yields an orange-yellow precipitate of cobalto-cyanide of lead. With chloride of cobalt, absolutely free from nickel, it gives a deep green precipitate, the cobalto-cyanide of cobalt and potassium.

Action of Trimethylamin on the Sulphide of Carbon.—A. Bleunard.—These two substances react upon each other with some violence, forming sulphocarbamate of trimethylamin.

Biedermann's Central-blatt.

Heft 12.

On the Requirement and the Transformation of Matter in *Saccharomyces Mycoderma*.—A. Schulz.—Not suitable for abstraction.

Salicylic Acid as a Disinfectant.—Prof. Feser.—The author, in a prolonged series of experiments, found salicylic acid of no value, either as a prophylactic or in the treatment of putrid infectious disease, carbuncle, &c.

Revolution in Tanning.—Prof. Knapp proposes the use of a basic ferric sulphate instead of oak-bark or other tanniferous material. He adds to a boiling solution of copperas the quantity of nitric acid requisite for the peroxidation of the iron, and after the reaction is over adds more copperas. The hides are suspended in the cold solution at a suitable degree of concentration, and are ready in from two to four days.

Chemiker Zeitung.

No. 50, 1878.

According to Dr. Deite most of the French manufacturers of iodine who buy their weed-ash from the varec-burners obtain only 3'15 kilos. of iodine from a ton.

The yearly production of potash in France is estimated at 14,000 tons, 10,000 of which are obtained from beet-ashes and 1000 tons from the suint of wool.

The importation of American leather into Germany has increased from 23,738 cwts. in 1868 to 155,773 cwts. in 1875. A strong demand for protective duties has arisen among the German tanners.

A successful competitor at the late Paris Exhibition offers his bronze-medal as a contribution to the lottery, as it was awarded him without any examination of the quality of his exhibits.

A long list is given of the substances used—apparently in France—for "denaturing" common salt to be used for agricultural or technical purposes. Some of these additions must greatly increase the price.

Melted gallium dissolves aluminium even below 15°, forming liquid or semi-liquid amalgams which oxidise very slightly on exposure to the air, but decomposed water powerfully, the gallium being liberated in the form of metallic globules.

Dr. Kayser, after examining pigments such as white-lead, zinc-white, chrome-yellow, &c., finds that in addition to the heavy-spar, the quantity of which is stated by the seller and is allowed for in the price, gypsum is likewise present.

Prof. Schwalbe contributes a judicious essay on chemical nomenclature. He considers it unwise to attempt the introduction of new names for long-known compounds, and thus to carry us further and further away from the desired goal,—a universally intelligible terminology.

Doubts are expressed whether the electric light can compete with coal-gas from a commercial point of view.

The dangerous character of lead-compounds is shown by the fact that in the years from 1838 to 1847 no fewer than 3142 patients suffering from lead-cholic were admitted into the hospitals of Paris, although there were at that time only two white- and red-lead works in the city. Of these cases 112 proved fatal.

Plicque estimates the total yearly production of artificial ultramarine at 10,000,000 kilos.

Incrustation of Lead Pipes with Sulphide of Lead.—A hot concentrated solution of sulphide of sodium is

allowed to flow through the pipes for ten to fifteen minutes. They then appear as if coated within with a grey glaze, and water afterwards passed through them remains free from lead.

According to *Dingler's Polyt. Journal* the skin of the sting-ray (*Raja clavata*) is now used in place of isinglass for the clarification of liquids, e.g., beer.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin, No. 13, 1879.

Conversion of the Nitriles into Imides (Fourth memoir).—A. Pinner and F. Klein.—The authors here examine the action of hydrochloric acid and alcohol upon hydrocyanic acid, which gives rise to ammonium chloride, ethyl chloride, formic ether, diethyl-glyoxylic amide, and diethyl-glyoxylic ether. When the same compounds react upon cyanogen the result is a predominating quantity of oximide ether, and secondarily chlor-ethyl, formic ether, and urethan. The authors have also studied the action of hydrochloric acid and alcohol upon propionitrile.

On Butyl-chloral-cyanhydrate.—A. Pinner and F. Klein.—The authors study the behaviour of this compound with ammonia, urea, acetyl-chloride, concentrated sulphuric acid, hydrochloric acid with alcohol, and other compounds. They attach particular interest to the action of ammonia upon trichloroxy-valerianic acid.

On Naphthyl-phospho- and Arsenio-Compounds.—W. Kelbe.—An account of naphthyl-phosphorous acid, diethyl-naphthyl-phosphin, triethyl-naphthyl-phosphonium iodide, dinaphthyl-phosphinic, and naphthyl-arsinic acid.

Determinations of Specific Weights.—F. W. Clarke.—Not susceptible of useful abstraction.

Etherification of Primary Alcohols.—N. Menshutkin.—The author points out and rectifies certain errors in his paper, *Berichte*, x., p. 1728.

Action of Nitrous Acid upon Non-saturated Hydrocarbons.—Paul Tönnies.—In this preliminary communication the author mentions that if a saturated solution of potassium nitrite is brought in contact with a solution of the above compounds in glacial acetic acid, substances are formed which appear as addition-products of N_2O_3 .

Preparation of a Series of Magnetic Compounds of the General Formula RO, Fe_2O_3 or $R''Fe_2O_4$.—Karl List.—The author has obtained and examined the ferrates of lime, magnesia, manganese, zinc, nickel, copper, and lead.

On Cinchonin and Cinchonidin.—Z. K. Skrap.—To the former of these the author ascribes the formula $C_{19}H_{22}N_2O$, and considers that cinchonidin has exactly the same composition.

Remarks on the Previous Paper.—O. Hesse.—The author finds the amount of carbon in cinchonin decidedly higher than does Skrap.

Analysis of the Mineral Spring "Tenniger Bad" in Somvixer Tobel.—R. Meyer.—The water contains an unusual quantity of strontium.

Angelic Acids of Different Origins.—W. v. Miller.—Frankland and Duppa's methyl-crotonic acid is distinct from Neubauer's angelic acid. The author's is a new isomer, of the formula $C_5H_8O_2$.

Preservation of Drinking Water.—Hugo Schiff.—The author recommends salicylic acid for the preservation of drinking water and brine with 1 part per 1000 of purified carbon disulphide for the preservation of zoological specimens.

Oxidation of Metaxylol-sulphamids.—Oscar Jacobsen.—A controversial paper with reference to the communication by Iles and Remsen (*Berichte*, xi., 1326).

Dibrom-metaxylol-sulphonic Acid.—O. Jacobsen and E. Weinberg.—The authors examine the soda-salt, the acid chloride, and the amid.

On Paraxylidin.—W. Schaumann.—Paraxylidin is an oily liquid lighter than water, colourless when recently prepared, but turning yellow on exposure to the air; abundantly soluble in hot water, and boiling at 220° to 221° . It forms with acids well-defined salts.

Action of Potassa upon Tetra-nitro-diphenyl-urea.—S. M. Losanitch.—The result of the reaction is a green, solid body of the composition $C_{13}H_6N_6O_9K_2$.

On Lotura Bark.—O. Hesse.—The author has isolated from this bark three alkaloids, which he names loturin, colloturin, and loturidin, the properties and compounds of which he here describes.

Certain Substitutes for Quinin.—O. Hesse.—The Australian tree *Alstonia constricta* was formerly supposed to contain quinin; recent observation has instead merely detected alstonin, a bitter principle not possessing basic properties. Ditain, a principle obtained from the bark of *A. scholaris* is also no alkaloid. Crossopteryx bark has been stated to contain quinin, but in the author's opinion it is little better than bad fire-wood.

Remarks on Mr. Rice's Memoir on the Cinchona Alkaloids.—O. Hesse.—The salts of quininid, which Rice takes to be conchinin, do not contain the latter base.

Reduction of Aceto-phenon.—K. Buchka.—A preliminary reply to Engler's paper (*Berichte*, xi., p. 934).

Adulteration of Wine.—F. v. Lepel.—The author gives the spectroscopic reactions of a mixture of magenta and the juice of *Beta vulgaris*.

On Aurin.—R. S. Dale and C. Schorlemmer.—The authors explain the formation of aurin by the following equation:—

Determination of Nitric Acid as Ammonia.—E. A. Grete.—The author, on heating pure saltpetre with xanthogenate and soda-lime, obtained almost exactly the whole of the nitrogen present in the state of ammonia.

MISCELLANEOUS.

Royal Institution of Great Britain.—The Managers have decided that the next Actonian Prize shall be awarded in 1879 to an Essay illustrative of the Wisdom and Benevolence of the Almighty; the subject being "The Structure and Functions of the Retina in all Classes of Animals, viewed in relation with the Theory of Evolution." The Prize is One Hundred Guineas, and will be awarded or withheld as the Managers shall think proper. Competitors for the Prize are requested to send their essays (with or without their names being affixed) to the Royal Institution, addressed to the Secretary, on or before October 1, 1879. The adjudication will be made by the Managers in 1879.

NOTES AND QUERIES.

Oils.—(Reply to R. J.).—I think that your correspondent R. J. will find the information he requires in the article on Oils in "Ure's Dictionary." F. C. Calvert has also published a paper in the Pharmaceutical Society's *Journal*, xiii., 56, upon the "Analysis and Detection of Impurities in Oils."—H. A. LAWRENCE.

TO CORRESPONDENTS.

Max Jordan.—We regret that we are unable to give our correspondent the information he desires.

Lavon.—Morfit's treatise on Soap, published by Trübner and Co.

Merrick.—Apply to the Secretary of the Society at Burlington House for a nomination form, which has to be signed by a certain number of Fellows of the Society, some of whom must have personal knowledge and others general knowledge of a candidate.

J. C. Harvey.—"Sutton's Volumetric Analysis," published by Churchill.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1000.

SILICIURETTED HYDROGEN.

We have received from Dr. Theodor Schuchardt, of Goerlitz, a specimen of a new body, which he calls silicium strontium. It is formed from the preparation of metallic strontium by electrolysis, but no particulars are given as to the substances present or the reaction by which it is formed. As received from Dr. Schuchardt the compound is a grey powder with a slight odour resembling phosphuretted hydrogen. When mixed with dilute hydrochloric acid a rapid evolution of the spontaneously inflammable siliciuretted hydrogen takes place. No particulars as to price are mentioned, but if obtainable in quantity this compound will probably be the readiest source of siliciuretted hydrogen.

W. C.

MEANS OF DETECTING THE ADULTERATION OF SAFFRON.

To detect adulteration with *Calendula flowers* (Feminelle), it is merely required to moisten a few flowers, and to rub them singly with the finger on white paper. The genuine flowers will give a fine rich yellow colour, whilst the Feminelle will only yield a violet reddish hue. It can also be easily detected by soaking the suspicious flowers in pure or, better still, distilled water. The real saffron will retain its fine red colour after hours, whilst the Feminelle will lose its artificial tint within a short time.

To detect an admixture of *Honey and Barytes* it is merely required to put a pinch of saffron in a tumbler with pure clear water (also in this case distilled water is preferable), and agitating it for a few minutes. Adulterated saffron will at once turn the water cloudy, and even small particles of dust may be seen falling to the bottom, which, on pouring the water carefully out, will be found to be a slimy, sand-like mass. With pure saffron the water will remain clear, showing a fine pure yellow colour, which, according to the quality of the flowers, will be more or less intense. Five or ten minutes suffice for these experiments.

PRELIMINARY NOTE ON THE ACTION OF SEA-WATER ON THIN IRON AND STEEL PLATES.

By SERGIUS KERN, M.E., St. Petersburg.

Thin iron and steel plates were subjected to the action of sea-water in the following manner:—

The specimens were 0.076 metre square and 0.00317 metre thick (one-eighth of an inch). They were placed (four samples of iron, four samples of steel plates) in wooden boxes containing sea-water, 2 litres in each box. The sea-salt was obtained from the north shores of France and dissolved in water; the specific gravity was 1.027 when the salt was added.

The specimens were immersed in this solution for thirty days, next dried between filter paper, and finally in an air-bath at 35° to 40°; then they were weighed.

All the plates before the experiments had a smooth surface, and were of the best manufacture. The chemical composition of them being as follows:—

I. Steel Plates.

	Per cent.			
	I.	II.	III.	IV.
Carbon ..	0.290	0.300	0.180	0.234
Manganese ..	0.380	0.412	0.275	0.178
Sulphur ..	0.010	0.010	0.012	traces
Phosphorus ..	0.005	0.008	0.010	0.032
Silicon ..	0.015	0.011	0.010	0.021

II. Iron Plates (Average Analysis).

Carbon ..	0.110 per cent.
Manganese ..	0.187 "
Sulphur ..	0.010 "
Phosphorus ..	0.004 "
Silicon ..	0.008 "
Copper ..	traces "

In the steel plates, in Nos. II. and III., traces of copper were observed. The other two steel plates contained no copper.

In the annexed table is shown the loss of the plates during the action of the sea-water upon them.

III. Action of 100 litres of Sea-water (Sp. Gr. 1.027) on one Square Metre of Iron and Steel.

1-inch Plates.	Loss in Grms.
1. Steel ..	22.75
2. " ..	22.34
3. " ..	21.83
4. " ..	21.96
1. Iron ..	25.78
2. " ..	25.54
3. " ..	26.04
4. " ..	27.44

To come to some conclusion further experiments are wanted, which are at the present time commenced, but the author believes that it is preferable to use steel for the skin of the ships. Certainly, in using steel much will depend on the manufacture and the composition of it, and many equivocal results may be obtained during experiments on the action of sea-water, owing to the more or less compactness of the plates. The best control in this case may be the determination of the specific gravity of the plates.

ON THE DIRECT PROCESS OF MAKING WROUGHT-IRON AND STEEL.*

By CHARLES M. DU PUY, C.E.

ABOUT one year ago I had the honour of addressing this Institute on the direct manufacture of iron from the ore. I then briefly referred to the various efforts that had been made in that direction, reaching over the best part of the past century, and closed the paper by describing a method, which, from various experimental and practical tests, seemed likely to promise usefulness in the arts.

It may be remembered, by this process the ore, carbonaceous matter, and fluxes, in the proper proportions, are ground together and mixed at the same time, and then filled into annular sheet-iron cases, holding from 100 to 200 pounds. Ten to twenty of these cases, with spaces between them, are subjected to the gradually increasing heat of a reverberatory furnace, and in about five hours on the average the ore and cases settle down, without work upon them, to about one-third their original height, becoming welded into quite compact lumps of iron, interspersed with liquid slag. These metal lumps are either then removed separately from the furnace, or several of them being welded together at the same heat, are forged or squeezed and rolled to "muck-bar."

* A Paper read before the Franklin Institute, November 20, 1878.

This process differs from all others, and it is exactly the reverse of the forge-fire and the blast-furnace methods. In those, a tuyere conducts a stream of oxygen into close contact with the particles of ore, while in this process the moderate heat prevents the combination of phosphorus with the iron, while atmospheric contact is excluded during reduction, and a reflected heat from the roof is furnished, for absorption during the transition to metal. It is to this peculiar treatment that is ascribed the high quality of the iron for steel purposes. It is what may be termed a *baking* process, which is conducted at a comparatively moderate heat to *eliminate phosphorus*, and in which the ore is kept out of the reach of oxidising influences, and to this the high value for steel is attributable.

At the time I addressed you I had licensed Messrs. Miller, Metcalf, and Parkin, of Pittsburg, Pa., to work the process at their Crescent Steel Works. Their forge and furnace was not completed until some time in last January, when for several months thereafter they carefully tested the iron which was deoxidised with charcoal by this method, in the various ways customary to determine the value of iron for high grades of steel. The result of these investigations brought forth the unqualified endorsement of this firm that the iron so produced from our native ores, for steel purposes, is equal in every respect to the most costly grades of Swedish iron.

Although the production of fine steel iron, reduced with charcoal by this process, was a step forward, yet the consumption of high grades of steel is comparatively limited, being mostly used only for tools of various kinds requiring great endurance. In order to enlarge the uses of this superior make of iron, it became apparent that its cost must be cheapened by deoxidising the ore with waste anthracite dust or refuse coke-dust, instead of charcoal.

To determine the practical value of anthracite dust, a series of more than fifty experiments were conducted, during the month of August last, at the forge at Reading, Pa. In these experiments, with anthracite dust, were used magnetic ore from near West Point, N.Y., Dickinson ore from northern New Jersey, Cornwall ore from Lebanon Co., Pa., Cumberland Valley ore from Maryland, Hematite ore from near Newark, Del., besides several other ores found near the line of the Philadelphia and Reading R.R.

These ores were worked both separately and variously combined, and with one exception, in every case, were reduced and forged to blooms. The blooms, which were re-heated, were drawn out smoothly under the hammer. The tensile strength of one of these bars was tried, and found to not exceed 45,000 pounds to the square inch.

A couple of crucibles of steel were made from a part of the iron which had been re-heated and drawn out, and the ingots were forged and used for planing tools. They stood forging and tempering well, comparing favourably, in endurance, with steel usually used in planing iron.

The object of testing iron reduced from the ore with *anthracite* coal-dust, for tool steel, was not so much with the expectation that at the first trial it would work well in planing iron in competition with steel carefully prepared from *charcoal* iron, but to determine, in a general way, the quality of the metal for steel purposes, of superior quality and in large quantities, by the open hearth. The result of this crucible test surpassed expectations and was very gratifying, from the fact that it is believed to have been the first instance where good tool steel was ever made by a direct process, on a practical scale, from iron deoxidised with *anthracite* coal-dust, and confirms the belief that anthracite dust will eventually be largely used to produce steel of high quality, cheaply and in large quantities.

Besides testing the ores before named, at the Reading forge, iron scale from the rolls (which is almost pure oxide of iron) was reduced alone with anthracite dust, and was also mingled with ore and anthracite, and in both cases was found to forge well into good blooms.

At the same time with the foregoing experiments, the ul pho oxides or refuse ore remaining after extracting

sulphur for sulphuric acid from the iron pyrites, at the New Jersey Chemical Works (commonly known to the trade as "Blue Billy"), was also reduced by this process with anthracite coal dust, and forged well into a bloom. This specimen was some time afterwards re-heated, rolled, cut up, and piled with about one-third of its weight of muck-bar from common puddled iron, and plated out well into smooth sheets of No. 26 iron. This last experiment is not of much value for this country, because very little sulphuric acid is made from pyrites, but in Europe probably not less than a million tons of this refuse ore is now annually almost wasted, because of the difficulty of economically utilising it.

These Reading experiments were the more gratifying from the fact that the process was quite successfully conducted in a reverberatory furnace, not well adapted to the purpose. This furnace had some time before been specially arranged to test the use of anthracite coal-slack, by burning it in fires of 4 or 5 inches thickness, on what is commonly termed "the Wooten grate-bars." As these thin fires required renewal every 15 or 20 minutes, the frequent opening of the door for replenishment exposed the ore so often to atmospheric re-oxidation as to make the furnace unsuited to the process. Besides this, the fire and flue bridge-walls, which had been constructed very low, and could not be very well raised owing to the lowness of the roof, caused the cases of ore to be exposed to the direct action of the blast and draught as it passed through the furnace into the stack.

Following up these interesting experiments during the month of September last, a sand-bottom scrap-heating furnace was altered at the Sligo Iron Works at Pittsburg for the purpose of testing this process further, by throwing the lumps of metal into a Burden Squeezer, and then rolling them to "muck-bar" at the same heat. Hitherto they had usually been forged to blooms under a hammer, and afterwards re-heated to be drawn to bars.

This furnace was operated experimentally with 32 heats. There was found no difficulty in making balls to pass through the squeezer and muck rolls at the same heat, just as ordinary puddle balls from pig-iron is squeezed and rolled at the same heat to muck-bar; but in order to fill the squeezer, which required balls of 150 to 200 pounds to secure a good compression, it became necessary to weld and press several of the lumps of metal together in the furnace at a heat so high as to cause the alkali to drip more or less from the mass, and soften the sand-bottom. As the balls were thus compressed and rolled in the fused sand an unnecessarily large portion of the iron was thereby cut by the sand and wasted to a silicate of iron, so that the yield from Republic ore which, before the bottom became softened, produced 53 pounds of iron in muck-bar from 100 pounds of ore charged, and which it was expected would have been brought up to 60 pounds of iron from 100 pounds of ore, gradually became very much lessened, showing conclusively that reduced yield followed the softening of the bottom, and determined the necessity of a "cinder-bottom" in order to save the iron.

To compress and weld several of these masses of metal together in the furnace, in order to have them enter and fill the squeezer, *really comprised all the labour required during the heat*. The cases were 15 inches diameter and 14 inches high, holding about 135 pounds of ore besides the coke and fluxes. By making the cases very little larger, say 16 inches diameter and 16 inches high, they would each produce about 100 pounds of iron, and by withdrawing each separately to the squeezer, all furnace manipulation of the metal would be avoided. Then, aside from maintaining the fire and charging and discharging the metal, all the labour really needed during the heat would be to change the damper once or twice, enabling an ordinary heater to regulate all the furnaces in the largest mill.

The fire- or grate-surface of this Pittsburg furnace was 4 feet square, and the space between the bridge-walls was 9 feet by 5 feet in width. The bottom was of sand,

set hard by heat. The flue-bridge was built up within 3 inches of the roof. The stack was 18 inches square inside. A fan-blast was used, part of the air passing under the grate-bars, and part, being heated, was passed through and over the fire-bridge.

In these several experiments it was found that, although the opening between the flue-bridge and roof for the escape of the spent products of combustion into the stack was lessened more than one-half the size from what it was when, with less capacity, the furnace had been used for heating scrap-iron, still the heat was so intense as to soften and render useless the damper rod at the top of the stack, which had previously stood twelve years, requiring renewal three times during these experiments. The conclusion drawn from these accidents was that the grate-surface of this furnace was amply sufficient to supply the accumulating heat for a length of 14 or 15 feet between the bridge-walls instead of 9 feet, thereby nearly doubling the capacity of the furnace with the same consumption of fuel.

Expensive fluxes, such as soda, manganese, &c., have been abandoned, as it has been now conclusively proved that a proper mixture of aluminous and silicious ores with lime, to produce a non-flowing glassy slag, is all that is required. This glassy slag being mingled among the particles of ore, covers and seals them from re-oxidation from furnace heat during the process of reduction. When either of these glass-making constituents are not available in the proper proportion, in the ore, ordinary sand, or clay, in the proper proportions, may be added to the lime and mixed together without injury to the metal, as the glass is readily compressed out of the iron by the hammer or squeezer.

During these experiments No. 26 sheet-iron was rolled out at the mill from common puddle bar, being found to answer equally as well for cases as well finished sheets from the best iron.

It has now been demonstrated that good steel can be made by this process from iron deoxidised either with charcoal, anthracite-dust, or coke-dust. The carbon in all these fuels being alike, and as the ash of either, along with the earthy impurities of the ore, be they more or less, may be readily reduced to a glass by a proper mixture of lime and ores through chemical analysis, and so utilised as a covering of the metal during deoxidation, and compressed from it afterwards—it follows the truest commercial economy is found in using that form of carbon which is of least value.

In the coke-making bituminous regions, the refuse coke-dust is disposed of in waste heaps and often burnt; while from the beginning of anthracite mining, mountains of anthracite slack remain standing monuments of our wastefulness. These wasted fuels by this process offer a premium for the production of cheap steel.

Any process that will not withstand the closest economic scrutiny is justly recognised as valueless in the arts; it is therefore proper to remark that the investigations at Reading and Pittsburg during the past year, although conducted in furnaces not specially adapted to the process and often amid inconveniences inseparable from experiments surrounded by the activity of regular mill-work, still nevertheless substantially confirm the view heretofore asserted, that a true commercial economy cannot fail to result from a systematic working of the process.

When it is considered that this mode of making iron frees it almost entirely from phosphorus, which goes almost altogether into the slag as explained in my former paper.

That a furnace at present prices for material and labour, in which from 1 ton to 1½ tons of blooms may be produced every twenty-four hours, will not cost over 800 dollars to 1000 dollars.

That a little lime in combination with ore and waste coal-slack has been substituted for more expensive fluxes and is found sufficient to supply the glassy covering for the metal.

That No. 26 sheet-iron for cases is now found to be

good enough when plated out from common puddle bar, and that the cases are very simply and cheaply made, needing neither tops nor bottoms.

That two men, in ten hours, with a 15 horse-power engine, will grind, mix, and fill the cases with the ore mixture for 7 tons of blooms.

That the furnace work is confined to charging, discharging, and firing the furnace, there being no necessity whatever for manipulating the metal from the time it is charged in the furnace until brought to the hammer or squeezer, thus greatly simplifying and cheapening what by the puddling process is excessively laborious and expensive work.

That the masses of metal, as one by one they are squeezed to blooms, may then be transferred in the heated state to the open-hearth bath, and there quickly melted along with the other steel-making material for the highest quality of steel.

When all these points are well considered it may be clearly understood that in localities as favourably situated for instance as the line of the Philadelphia and Reading Railroad, where Cornwall and other ores can be laid down at an average of 3 dols. per ton, and where anthracite fuel and coal-dust may be obtained proportionally low—that blooms on a large practical working scale, nearly freed from phosphorus, may be manufactured equally as good for 18 dols. or 20 dols. per ton, as now cost from 38 dols. to 50 dols. per ton. Similarly great inducements are likewise offered in Northern New Jersey, where fuel and ore can be brought together at about the same cost. In the bituminous coal region fuel is correspondingly low, and coke-dust can be had for the freight, offering favourable manufacturing advantages.

In a few words, this process offers a cheap mode of making a high quality of metal for steel, by an inexpensive plant, enabling manufacturers to utilise idle rolling mills at trifling cost.

THE SEVEN FUNDAMENTAL TYPES OF ORGANIC CHEMISTRY,

AS VIEWED AND INTERPRETED FROM THE STANDPOINT OF THE "TYPO-NUCLEUS" THEORY.

By OTTO RICHTER, Ph.D.

IMPRESSED with the deep scientific import and significance of certain far-reaching and well-matured original ideas and speculations of my own, I have deemed it my duty of again addressing the Chemical Profession in order to submit to them for closer examination a second and even more abundant crop of valuable and interesting generalisations which I have been able to gather on the wide and fruitful field of speculative research. It may not be amiss to state here that the task set before me, and commenced in full earnest some thirty years ago, was persevered in with the avowed object of contributing my share also towards the foundation of a more rational, comprehensive, and harmoniously elaborated system of chemical philosophy. As a further proof of the sincerity of my motives and aspirations, I have now, I flatter myself, succeeded in concocting an entirely novel and original theory of molecular substitution, which promises to meet all the more pressing wants and requirements of modern organic and inorganic chemistry. It is with the aid of this latest and still vigorously expanding offspring of my private meditations, reared as it has been under the fostering care of those purer doctrines and principles which I had occasion to broach and to discuss in a series of papers under the head of my "Typo-Nucleus" Theory, that I hope to shed a bright and powerful light upon sundry vexed and seemingly insoluble questions, concerning which the

History of our science has recorded so many stirring, but in their final results comparatively barren and unprofitable, controversies. Having, in the course of my speculative travels, made the startling discovery that a grave and all-pervading error had been committed on the part of our leading theorists in not sufficiently discriminating between two in their *modus operandi* essentially different chemical processes, I have considered it imperative on me to expose this fatal error, the offshoot no doubt of an overbold and over-hasty generalisation, and, as far as lay in my power, to counteract its evil influences and tendencies.

The two processes just alluded to, and which are constantly encountered in our laboratories, and not unfrequently in one and the same reaction, are on the one hand the process of direct chemical union by the addition of new elements to those already combined; and, on the other hand, the process of indirect chemical union by the substitution of new elements for those already combined. Now, I venture to maintain, that our chief chemical authorities and advisers, from neglecting to draw a clear and distinct line of demarcation between these two radically different methods of proceeding, have beguiled themselves and their numerous followers into the adoption of a style of writing which, by inundating the chemical market with a seemingly very plausible but really unsound and unpalatable species of sham literature, threatens not only to create a distaste for more solid work, but likewise to seriously retard the healthy growth and development of theoretical chemistry.

With these well-intentioned and, I am afraid, well-founded strictures and objections, I shall at once proceed to enlarge on some of the more salient doctrines and principles of my own system, a brief exposition of which will, I trust, enable the reader to appreciate the true merits and scientific value of my new substitution theory.

In striking contrast with the prevailing biatomic hypothesis, according to which the different kinds of elementary molecules are represented as consisting of two chemically identical atoms, cemented together by means of one, two, three, or more reciprocally attracting centres of force, my system is founded upon the polyatomic hypothesis, according to which the different kinds of elementary molecules, though likewise regarded as being composed of an equal number of atoms, are at the same time believed to enclose within them a considerably larger number of such atoms than are generally assumed on the other side. These primordial, and in all probability spherical, particles of ponderable matter are held to differ from each other in point of size, specific gravity, and electro-polar energy, according to the species they belong to, but they have, each and all, this highly characteristic feature in common, that they are symmetrically disposed and grouped together in their respective molecules with reference to the three conjugate axes of space, and in obedience to some omnipotent fundamental law of atomic collocation and arrangement. Another remarkable and noteworthy feature of the molecules before us, which in my notation are expressed by the general symbol E_2 consists in this, that, while they are not held to correspond to entities enjoying a separate and independent state of existence, they are at the same time held to be of immense theoretical value and importance, inasmuch as they furnish the only solid and substantial basis on which I believe it possible to erect a truly rational and comprehensive system of chemical philosophy. A select number of these theoretically indispensable molecules have, as a reference, been embodied in the accompanying table, together with their respective symbols and atomic weight-equivalents, and it deserves special mention that the particular order in which these symbols are made to succeed each other is intended to convey an approximate idea of the relative electro-polar positions which the corresponding molecules are believed to occupy in the atomic edifice in conformity with the general electro-polar law of molecular collocation and arrangement.

Table of Chemical Elements, with their Symbols and Atomic Weight Equivalents.

First Division: Electro-positive Elements or Metals.

Symbols . . .	H ₂	K ₂	Na ₂	Ba ₂	Ca ₂	Mg ₂	Zn ₂	Pb ₂	Fe ₂	Cr ₂	Al
Atomic weights	2	78	46	137	40	24	65.5	207	56	52	27.5
Symbols . . .	Ag ₂	Pt ₂	Au ₂	Sn ₂	Hg ₂	Bi ₂	Sb ₂	As ₂	P ₂	—	—
Atomic weights	216	197.5	197	118	400	210	122	75	31	—	—

Second Division: Electro-negative Elements or Non-metals.

Symbols . . .	Si ₂	C ₂	Bo ₂	Te ₂	Se ₂	S ₂	T ₂	Br ₂	Cl ₂	Fl ₂	N ₂	O ₂
Atomic weights	28	12	11	128	79.5	32	254	160	71	38	14	16

In commenting on the contents of the preceding table I am far from maintaining that the relative places assigned to the various elements in the general electro-polar order of grouping are absolutely correct. I can only express my regret that, for want of proper experimental data, my researches in this direction have not as yet led to any satisfactory results, and I am bound to confess that, in order to fill up the numerous gaps, I have reluctantly allowed myself to be guided by the uncertain glimmer of fancied analogies and probabilities. Thus, for instance, I am unable to answer the question why K₂ should occupy the second place in the electro-polar order of grouping in preference to the third or fourth place; and, similarly, why Zn₂ should precede Pb₂ or any other metal. But, on the other hand, I hope to prove, with the aid of a great variety of valuable experimental evidence, that H₂ is really the most electro-positive of all the known elements, whereby it claims for itself the first or lowest place in the electro-polar order of grouping, while O₂ is really the most electro-negative of all the known elements, whereby it claims for itself the last or highest place in that order. I am further able to prove that the members of the non-metallic series—C₂; S₂; I₂; Br₂; Cl₂; Fl₂; N₂; O₂—are given in their proper order; while I think it highly probable that the members of the metallic series—Bi₂; Sb₂; As₂; P₂—are really succeeding each other in the manner indicated. This conjecture derives considerable support, at all events, from the unmistakable analogy which the series before us bears to the series I₂; Br₂; Cl₂; Fl₂, the atomic weights of whose members are observed to diminish as we ascend in the electro-polar order of grouping, a coincidence which, if not accidental, must be the outcome of some general law, to the jurisdiction of which not only the series in question, but various other groups of cognate elements, may likewise be found amenable.

Trusting that this particular field of speculative research may soon become better known and cultivated, I shall now proceed to describe the general method whereby that class of elementary molecules which form the theoretical basis of reasoning may become transformed into that other class of elementary molecules which are capable of enjoying a separate and independent state of existence, and through them into that endless multiplicity and diversity of compound molecules, the internal structure and organisation of which still continues to defy the argumentative skill and ingenuity of our shrewdest and most keen-sighted speculative chemists and physicists.

In pondering this momentous and seemingly inaccessible problem my efforts were at length rewarded with the important discovery that directly or indirectly the former class of molecules are destined to furnish the materials for the construction of seven distinct fundamental types or forms of molecular grouping, which, by their combination with each other, are further destined to furnish a vast number and variety of composite types, under which the whole immensity of organic and inorganic compounds may be systematically arranged and classified. The proper treatment of this subject requires that I should divide the before-mentioned seven fundamental types into three separate sets on the ground that each set owes its origin and formation to the aid and intervention of a distinct fundamental principle or agency. Accordingly, the first set of types is believed to stand under the immediate control of the principle of parity or physical principle, and

to embrace three fundamental types called respectively the Nucleus Type, the Outer Conjunct Type, and the Inner Conjunct Type. Again, the second set is believed to stand under the immediate control of the principle of calority of thermal principle, and to embrace two fundamental types, called respectively the Outer Subjunct Type and the Inner Subjunct Type. Finally, the third set is believed to stand under the immediate control of the principle of polarity or chemical principle, and to embrace two fundamental types, called respectively the Outer Adjunct Type and the Inner Adjunct Type.

(To be continued)

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, January 16, 1879.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

AFTER the announcement of visitors, the minutes of the previous meeting were confirmed. The following certificates were read for the first time:—W. Spottiswoode, P.R.S., T. Whitaker, J. L. MacMillan, J. A. Ogilvie, W. S. Lawson, V. H. Veley.

The first communication was made by W. H. PERKIN, F.R.S., "On the Action of Isobutyric Anhydride on the Aromatic Aldehyds." When an aromatic aldehyd is heated with normal butyric anhydride and a butyrate an angelic acid is obtained containing the hydrocarbon radical of the aldehyd employed. Thus, benzoic aldehyd yields phenyl-angelic acid, &c. The author has studied in the present paper the reaction which takes place when isobutyric is substituted for butyric anhydride. A mixture of cuminic aldehyd, isobutyric anhydride, and sodium isobutyrate was heated in sealed tubes to about 150° C. for twenty-four hours. On opening the tubes much carbonic anhydride escaped. The product was mixed with water, and boiled in a retort until the distillate was nearly free from oily matter. On cooling, the aqueous portion was separated from the thick oily product, and the latter boiled with an excess of a solution of sodium carbonate. The boiling alkaline solution was acidified, and deposited a thick oily acid. This was dissolved in petroleum spirit, and after some time the solution deposited oblique crystals. These proved on analysis to be a compound of cumenyl-crotonic and isobutyric acids. A similar experiment with benzoic aldehyd gave phenyl-crotonic acid. When isobutyric acid, prepared by repeated fractioning, and so, as far as possible, freed from propionic anhydride, was used, very much smaller quantities of the crotonic acids were obtained. The author estimated the amount of carbonic anhydride produced in the above reaction, and examined the oily matter which distilled over on boiling the products of the above reactions with water. It proved to consist principally of butenyl benzene, $C_{10}H_{12}$ (when hydride of benzoyl was used), boiling at 184° to 186°, yielding, on oxidation with chromic acid, benzoic and acetic acids. The author proposes to call it β -butenyl-benzene. Its dibromide and bromo derivative and the dibromide of the latter were prepared and examined. With cuminic aldehyd β -isopropyl-butenyl-benzene was obtained,—

It boils 8° lower than the α body. When cinnamic aldehyd was used, butenyl-cinnamene was obtained,—

It oxidises rapidly, and forms a red crystalline compound with picric acid. By heating the sodium derivative of or the hydride of salicyl itself, with isobutyric acid, ortho-hutenyl-phenol, $C_{10}H_{12}O$, was obtained as a colourless oil, boiling 223° to 225°, having a smoky and cedar-like odour; specific gravity = 1.0171. Many reactions of this substance are given in the paper. By treating paroxy-benzoic aldehyd in a similar way para-butenyl-phenol was obtained, boiling at 230° to 235°, crystallising at low temperatures. Similarly, from anisic aldehyd, β -para-butylen-anisole was obtained, fusing at +7°, $C_{11}H_{14}O$; it boils at 236° to 237°. In conclusion the author discusses the isomerism existing between the bodies obtained in the present research and those obtained previously by using normal butyric acid, and especially that of the butenyl benzenes.

After some remarks by the PRESIDENT and Drs. FRANKLAND and ARMSTRONG on the theoretical part of the above paper,

Dr. DUPRÉ read a communication "On Two New Methods for the Estimation of Minute Quantities of Carbon: (1) Gravimetric; (2) Chromometric; and their Application to Water Analysis," by A. DUPRÉ and H. WILSON HAKE. (1) The Gravimetric Method:—This method consists essentially in burning the small quantity of carbon in a stream of oxygen in an ordinary combustion-tube containing some granulated cupric oxide. One end of the combustion-tube is drawn out and bent downwards at an angle of 120°, so that it can easily be attached to a Pettenkofer tube charged with a perfectly bright solution of barium hydrate. The stream of oxygen passes through a long tube containing caustic potash before entering the combustion-tube, and before commencing the combustion the tube with the cupric oxide is heated to redness, and the oxygen passed until carbonic acid ceased to be evolved, as tested by passing through bright baryta-water. The Pettenkofer tube is charged with baryta-water, various precautions being taken to prevent the slightest access of any air containing carbonic anhydride, and connected with the combustion-tube. The substance is introduced and burned in the usual way. The carbonic acid is completely absorbed by the baryta-water. At the conclusion of the combustion the barium carbonate formed is filtered and washed by an ingenious arrangement completely out of contact with ordinary air, first with water saturated with barium carbonate, and finally with pure water. The Pettenkofer tube is then rinsed out with dilute hydrochloric acid, and the washings poured on the filter containing the barium carbonate. The barium chloride solution is then evaporated in a very small platinum dish, converted into sulphate by ignition with sulphuric acid, moistened with nitric acid, again ignited, and weighed on an assay balance. The following are results thus obtained with known quantities of sugar:—

Carbon Taken.	Carbon Found.
0.01344	0.01340
0.00755	0.00748
0.00535	0.00551
0.00390	0.00398
0.00137	0.00163
0.00079	0.00085
0.00034	0.00027

The method is therefore quite accurate enough for determining the carbon obtained from a litre of a first class potable water. The authors found the error of several blank experiments to be equal to three-tenths of a milligramme of carbon: they therefore subtract this quantity from each result. The chromometric method, or, as the authors name it, the nephelometric method, consists essentially in burning the carbon as above, but the carbonic acid is conducted into a standard solution of basic acetate of lead (2 per cent), and estimating the turbidity produced, as compared with that produced by the carbonic acid evolved under similar circumstances by a known and nearly equal quantity of carbon (sugar), the difference between the two being estimated by a Mills's colorimeter.

The authors find that the precipitate produced in the acetate of lead is very similar in appearance under widely different circumstances, and that it settles slowly. This method is extremely delicate, and a difference produced by 3-100ths of a milligram can be clearly estimated. The authors also propose, to prevent any chance of loss in scraping out a residue, the use of a collapsible silver-foil dish, which is placed inside a platinum dish for support, and when the residue is dry the silver dish with the residue is rolled up, and the roll introduced bodily into the combustion-tube. These dishes hold about 50 c.c. (They are made by Johnson and Matthey, and cost about 3s. 6d.) Using these methods, the authors estimated the carbon in a water, using 200, 100, 50 c.c., with the following results:—

Carbon in residue from 200 c.c. water gravimetric method equal 0.34 per 100,000.

Carbon in residue from 100 c.c. water nephelometric method equal 0.31 per 100,000.

Carbon in residue from 50 c.c. water nephelometric method equal 0.26 per 100,000.

It must be understood that the authors do not recommend the use of such small quantities of water, but the results show the delicacy of the processes. In conclusion, the authors suggest the use of the above methods for estimating the carbon in iron and the carbonic acid in air.

Dr. FRANKLAND said that every chemist must feel indebted to the authors for the very ingenious methods they had brought forward, methods which seemed to be sufficiently accurate and delicate for the purpose intended: there still remained, however, the estimation of the nitrogen, which was of equal importance with the determination of the carbon. He would like to ask whether the condition of the precipitate in the plumbic acetate did not vary somewhat with different conditions, *e.g.*, the rate at which the carbonic anhydride was evolved.

Dr. ARMSTRONG asked how the complete combustion of all the carbon could be ensured with the silver dish? Alkaline carbonates might be formed.

Mr. THORPE said that he had scraped out many water residues, and had never experienced any difficulty in the operation. An apparatus similar to that used by the authors had been employed by Fleming at Cheltenham College. He, however, decomposed the barium carbonate, and read off the carbonic anhydride evolved.

Prof. HARTLEY remarked that Dittmar had suggested methods for easily estimating the C and N in water residues: he absorbed the carbonic acid by soda-lime. The nitrogen was converted into ammonia by soda-lime, the ammonia absorbed in weak acid and Nesslerised.

Dr. DUPRE replied that the precipitate in the basic acetate of lead seemed to be remarkably uniform; that the water was evaporated with phosphoric acid, so that no alkaline carbonates could be formed; that although the residue from a litre of water might easily be removed, that from 50 c.c. could hardly be detached and transferred without loss.

Dr. FRANKLAND then read a communication "*On Stannic Ethide*," by E. FRANKLAND and A. LAWRENCE. In endeavouring to prepare stannous ethide by the action of zinc ethyl upon dry stannous chloride the authors discovered that the reaction was—

and that by its means stannic ethide could be prepared more conveniently and in larger quantities than has been possible hitherto. Fragments of fused stannous chloride were added to zinc ethyl contained in a flask cooled by immersion in water. As soon as the mixture ceases to fume in the air, when a sample is taken on the end of a glass rod, enough chloride has been added. The pasty mass is distilled in an oil bath. The distillate, which should contain some free zinc ethyl, is poured into water, the zincic hydrate dissolved in dilute sulphuric acid, and the heavy oily layer of crude stannic ethide separated and purified. The pure substance has, at 180° C., no action on aluminium, sodium, magnesium,

acetone and ethylic oxalate. It acts slightly on benzoic aldehyd. At ordinary temperature neither ammonia, carbonic anhydride, carbonic oxide, cyanogen, nitric oxide, oxygen, nor sulphuretted hydrogen affect it. Sulphurous acid is slowly absorbed, a crop of crystals being formed after some weeks. These were soluble in ether, and proved to be stantriethyl sulphate, identical with the sulphate of sesquistanethyl of Cahours and Buckston. The syrupy liquid, from which the above crystals had separated was found to contain stantriethyl hydrate combined with ethyl-sulphonic acid. The reaction was probably— $\text{SnEt}_4 + \text{SO}_2 + \text{O} = \text{SO}_2\text{Et}(\text{SnEt}_3\text{O})$. The reaction was tried when air was rigorously excluded during the absorption of SO_2 ; but the final products were the same; much metallic tin was, however, formed. The authors therefore infer that oxidation occurred during the solution and evaporation of the products.

The PRESIDENT said the above paper furnished us with a ready method of preparing stannic ethide, so that we could obtain it with facility if it was required as a reagent; it was singular that it should resist the action of so many substances.

The next paper was read by the SECRETARY; it was entitled "*On Aurin*," Part II., by R. S. DALE and C. SCHORLEMMER. In previous researches the authors stated that by the action of alcoholic ammonia on aurin, rosanilin was obtained, and a dilemma arose, that if aurin had the formula $\text{C}_{20}\text{H}_{14}\text{O}_3$, rosanilin could not have the formula which Hofmann had proved it to have, $\text{C}_{20}\text{H}_{19}\text{N}_3$. The authors therefore again prepared pure aurin and confirmed their previous analysis. Gräbe and Caro also assigned the same formula to aurin. Zulkowsky states, however, that the method employed by the authors yields wretched results, and cannot be used on the manufacturing scale. The authors, however, affirm in the present paper that under certain conditions, which they are not at liberty to divulge, a fairly good yield can be obtained. The authors have used two methods to purify aurin; one by conversion into ammonia aurin and the decomposition of the latter by hydrochloric acid, and a second by taking advantage of the fact that the solubility of aurin in alcohol decreases with the removal of the by-products. The analyses of pure aurin thus obtained completely confirmed the formula $\text{C}_{20}\text{H}_{14}\text{O}_3$. The correctness of the formula was also proved by E. and O. Fischer, who explained the above discrepancy by showing that the rosanilin obtained from aurin was para-rosanilin, $\text{C}_{19}\text{H}_{17}\text{N}_3$. The authors next consider the formation of aurin, which they consider takes place as follows:—

The paper contains the examination of several compounds and derivatives of aurin. Ammonia aurin, $\text{C}_{19}\text{H}_{14}\text{O}_3(\text{NH}_3)_2$. Tetra-brom-aurin, $\text{C}_{19}\text{H}_{10}\text{Br}_4\text{O}_3$. The authors have studied the action of acetyl-chloride and acetic anhydride on aurin. A white compound easily decomposed by hydrochloric acid was obtained with the formula $\text{C}_{19}\text{H}_{14}\text{O}_3 + \text{C}_4\text{H}_6\text{O}_3$, melting at 168°. Aurin forms unstable compounds with bases, but combines with acids to form stable salts, which crystallise well. The bodies formed with acetic, hydrochloric, sulphuric, and nitric acids were prepared and examined. Aurin also combines with sulphur dioxide to form a compound,—

Rosolic acid resembles aurin in the fact that it combines with acids to form salts; the authors therefore propose to call it rosaurin. In conclusion the authors thank Mr. O'Shea, who has performed the analytical work in the paper. Some beautiful specimens were exhibited in connection with this paper.

The next paper was "*On the Derivatives of Di-isobutyl*," by W. CARLETON WILLIAMS. Di-isobutyl prepared by the action of sodium on isobutyl-bromide boils at 108°, 745 m.m., and does not solidify at -17°. Sp. gr., at 0°, 0.7088; ref. ind., at 16°, 1.3901 for the red K line refraction equivalent, 63.78. The isoprimary alcohol from the

hydrocarbon has an orange-like odour and hot burning taste. It is liquid at -17° ; boils, 179° to 180° , 765 m.m.; sp. gr., at 0° , 0.841. On oxidation it yields iso-octylic acid, an oily liquid boiling at 218° to 220° ; soluble in alcohol and ether; almost insoluble in water; sp. gr., at 0° , 0.926. The most characteristic salts are those of strontium, calcium, and copper. Ethyl-iso-octylate is lighter than water; boils at 175° . The isosecondary alcohol is obtained in smaller quantities than the iso-primary; boils at 160° to 163° ; sp. gr., at 15° , 0.820. On oxidation it yields a keton, boiling at 159° to 161° ; sp. gr., at 14° , 0.865. The keton on oxidation splits into acetic, and probably isobutyric acids.

The next paper was "On the Action of Chlorine upon Iodine," by J. B. HANWAY. The author has re-examined the question as to the existence of the compound ICl_4 , and has come to the conclusion that such a body has no existence for two reasons. First, that the reaction for its formation is impossible, as no high chloride of iodine can exist in the presence of free iodine; and, secondly, that careful experiments by which chlorine is added to iodine in the most advantageous manner for the formation of a high chloride fail to indicate such a body.

The Society then adjourned to February 6, when the discussion on Dr. Tidy's paper "The Processes for Determining the Organic Purity of Potable Waters" will take place.

CORRESPONDENCE.

A CORRECTION.

To the Editor of the Chemical News.

SIR,—I am much obliged to Mr. S. E. Phillips for pointing out, in last week's CHEMICAL NEWS, an error of which I am guilty (in vol. xxxviii., p. 259) in inadvertently putting violuric (and diluturic) acids under the head of tartaric instead of malonic acid, to which latter they seem to be more directly related.—I am, &c.,

P. T. MAIN.

January 20, 1879.

THE NEW ARSENIC TEST.

To the Editor of the Chemical News.

SIR,—If your correspondents Messrs. Otis Johnson and William Johnstone will take the trouble to examine the CHEMICAL NEWS of April 18, 1873, they will there see described by myself the reaction of aluminium and an alkali on arsenical and antimonial solutions, together with the limits of the test.

The reaction involved is certainly not new, and was first published by me as a convenient modification of the Fleitman test, Al being used instead of Zn. My pupils have constantly used the test since the above date, and prefer it in rapidity and certainty to all others.—I am, &c.,

J. W. GATEHOUSE, F.I.C.,

Public Analyst for the City of Bath.

The City Analytical Laboratory,
34, Broad Street, Bath, Jan. 17, 1879.

OXIDATIONS AND REDUCTIONS.

To the Editor of the Chemical News.

SIR,—In my table of "Oxidations and Reductions," published in the CHEMICAL NEWS, vol. xxxviii., p. 228, is an error which I desire to correct. Iodine is stated to react with oxalic acid, forming hydriodic acid and carbonic anhydride, while, in fact, no reaction occurs.—I am, &c.,

HENRY B. PARSONS,
U.S. Dept. of Agriculture.

Washington, D.C., Jan 7, 1879.

INFLUENCE OF CHLOROFORM ON NITRIFICATION.

To the Editor of the Chemical News.

SIR,—I am at a loss to understand Mr. Hehner's notion of nitrification. I have always imagined that "nitrification" implied the production of nitric acid. This production of nitric acid, according to Schloësing, Müntz, and myself is prevented by the presence of chloroform. Mr. Hehner says that nitrification is not prevented by the presence of small quantities of chloroform, and he comes to this conclusion from experiments showing that ammonia increases in amount when a small quantity of chloroform is present. This increase in the ammonia he supposes to be due to a reduction of the nitrates in the solution by bacteria. How can these experiments prove that chloroform does not prevent nitrification? Does Mr. Hehner understand by "nitrification" the destruction of nitrates, or does he suppose that the destruction and production of nitrates are allied phenomena, both of which are due to the action of bacteria?

I can only repeat, in conclusion, that chloroform prevents the formation of nitrates. No statement has been made by myself, nor, as far as I am aware, by the French experimenters, regarding its influence upon the destruction of nitrates.—I am, &c.,

R. WARINGTON

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin,
No. 13, 1879.

Determination of Nitrogenous Organic Substances.

E. A. Grete.—The author finds great advantage in treating horn, wool, leather, &c., with concentrated sulphuric acid at a gentle heat previous to combustion. He suggests that the proportion of nitrogen in albuminoid bodies has been given too low.

Penta-brom-resorcin.—R. Benedikt.—On bringing penta-brom-resorcin and aniline in contact there are formed tribrom-anilin and tribrom-resorcin. Under similar circumstances phenol yields tribrom-phenol. Penta-brom-resorcin, if boiled with tin and hydrochloric acid, yields first tribrom-resorcin and then resorcin. The tribrom-reso-quinon on boiling with tin and hydrochloric acid yields tetra-brom-diresorcin.

On Mono-sulpho-lactic Acid.—C. Böttiger.—C. Schaß obtained this acid from α -chloro-propionic acid, and the author has prepared it from pyruvic acid. Both acids are identical.

On Glyoxylic Acid.—C. Böttiger.—In this fourth memoir the author describes the action of aniline upon glyoxylic acid.

Difference of the Absorption Spectra of one and the same Substance: A Reply to H. J. Moser.—H. W. Vogel.—The author points out that Moser has not given experimental proof for his assertions, and has imputed to him views which he has neither implicitly nor explicitly put forward.

Synthesis of Pyruvic Acid.—L. Claisen and J. Shadwell.—The authors prove that acetyl-formic acid, prepared from cyanacetyl, is identical with pyruvic acid.

On Dioxy-benzoic Acid.—L. Barth.—The author seeks to obtain from the formation and the behaviour of the etheroid and anhydroid derivatives of resorcin corroboration of their views on the constitution of dioxy-benzoic acid.

On Thymo-oxy-cuminic Acid.—L. Barth.—The author describes the preparation, properties, and derivatives of this acid at considerable length.

On Idrialin.—G. Goldschmidt.—The author finds this body to contain 91.71 carbon and 5.32 hydrogen, and declares that he cannot see why it should rank with the aromatic hydrocarbons.

Double Salts of Cuprous Hyposulphite (Second Memoir).—F. Kessel.—Not suitable for abstraction.

On α -Oxpara-toluylic Acid.—E. v. Gerichten and W. Rössler.—The authors pronounce this acid identical with Flesch's oxy-toluylic acid.

Action of Fuming Nitric Acid and of Nitrous Acid upon Benzol-sulphinic Acid.—W. König.—The author seeks to ascertain whether $C_{18}H_{16}N_2S_3O_6$ contains intact the three benzol-sulphuryl residues.

On Organic Thio-compounds.—O. Wallach.—The author examines the behaviour of alkyl-bromides and iodides upon sodium-thiacetamid.

New Mode of Formation of Phenyl-glyoxylic Acid.—L. Claisen and F. H. Morley.—Ethyl-glyoxylic ethyl-ether and mercury diphenyl are readily transformed with little loss into phenyl-glyoxylic ethyl-ether and mercury mono-phenyl-chloride.

On Triphenyl-methan.—E. and O. Fischer.—The authors have obtained from this compound both triphenyl-methan-cyanide and triphenyl-acetic acid. They effected this object by heating triphenyl-methan-chloride with an excess of mercury cyanide.

Action of Halogens upon the Salts of Guanidin.—J. Kamenski.—In this memoir the author examines the behaviour of guanidin carbonate with bromine and chlorine.

Chrysarobin and Alleged Chrysophanic Acid in Goa-powder.—C. Liebermann and P. Seidler.—The authors hold that the substance originally present in this powder is not chrysophanic acid, and that acid, as actually detected by Attfield, they consider a product of conversion. For the original substance they propose Attfield's synonym chrysarobin.

Synthesis of Anthrarufin and Chrysasin from Anthracen.—C. Liebermann.—On treating anthracen with sulphuric acid the authors obtained two disulpho-acids, one of which lead through an easy series of conversions to anthrarufin (Schunck and Römer) and the other to chrysasin.

Disulphanthracenic Acid and its Conversion into Anthrarufin.—C. Liebermann and K. Böck.—A detailed description of the former reaction mentioned in the previous paper.

Formulae of Rhamnetin and Xantho-rhamnin.—C. Liebermann and O. Hörmann.—The authors assign to rhamnetin the formula $C_{12}H_{16}O_5$, and to xantho-rhamnin $C_{18}H_{26}O_{22}$.

Certain Derivatives of Cœrulignon.—H. Ewald.—A description of hydrocœrulignon potassium, hexamethoxyl-diphenyl, dibrom-hexa-methoxyl-diphenyl, and dichlor-hexa-methoxyl-diphenyl.

Three Isomeric Tolidins.—A. Goldschmidt.—In addition to the tolidin obtained by Petrie the author has obtained two others. The paper contains an account of meta-azo-toluol, meta-hydrazo-toluol, and sulphate of tolidin.

On Hydrocarbons obtained by the Action of Aluminium Chloride upon Chlor-methyl and Benzol.—E. Ador and A. Rilliet.—An examination of xylole.

Determination of Phosphoric Acid as Ammonic Phospho-molybdate.—R. Finkener.—Hydrochloric and nitric acids hinder or delay the formation of the yellow precipitate, whilst dissolved molybdic acid promotes or accelerates it. Hydrochloric acid in the solution acts more powerfully than nitric, and ammoniac nitrate more powerfully than ammoniac chloride. The author's solution con-

tains per litre 33 grms. molybdic acid, 141 grms. N_2O_5 and 19.4 grms. NH_3 . When precipitating phosphoric acid the quantity of free nitric acid must always be more than enough to prevent the formation of a precipitate in the absence of phosphoric acid, but a considerable quantity of nitrate of ammonia may be dissolved in the liquid. In ordinary cases the phosphoric acid will be totally precipitated in less than twelve hours, if so much molybdic mixture is added as to make up four times the volume of the phosphoric solution, and if in every 100 c.c. of the mixture there are dissolved 25 grms. nitrate of ammonium. For washing the precipitate is employed a strong solution (20 per cent) of ammoniac nitrate, to which at first one-thirtieth of its volume of nitric acid is added. The washing is completed when the washings are no longer coloured by potassium ferrocyanide. The precipitate may be brought into a condition fit for weighing by the following operations:—After removing most of the ammoniac nitrate by means of water the contents of the filter are washed into a weighed porcelain crucible. Anything adhering to the paper is dissolved in a little warm dilute ammonia, the solution is concentrated by evaporation, nitric acid is added in excess, the whole is quickly poured into the porcelain crucible, the liquid is expelled by evaporation, and the nitrate of ammonia driven off by a flame moderated by wire gauze. The residue is hygroscopic, and must be cooled over sulphuric acid and quickly weighed in the covered crucible.

Diazo-compounds of the Fatty Series (First Memoir).—W. Zorn.—By treating ethyl-iodide with silver nitrosyl the author obtained a compound C_2H_5NO , almost as readily and as violently explosive as the chloride of nitrogen.

Discovery of Vanillin in Siamese Benzoin.—P. Jannasch and C. Rump.—This paper contains merely the analytical evidence that the substance detected was vanillin.

Preparation of Nitrous Acid.—G. Lunge.—For the preparation of nitrous acid, whether by means of arsenious acid or starch, should be used nitric acid of sp. gr. 1.30 to 1.35, and almost entirely free from hyponitrous acid.

Action of Ethyl Iodide upon Silver Maleate and Fumarate.—R. Anschütz.—The author's object is to decide the isomerism of maleic and fumaric acids by a comparative study of their derivatives.

On Alizarin Blue.—C. Græbe.—The author shows by his experiments that the correct formula for this compound is $C_{17}H_9NO_4$. By heating it with zinc-powder he obtains a new base, $C_{17}H_{11}N$, whose salts are all golden yellow, and in solution display an intense green fluorescence.

Simple Method for Obtaining the Aldehydins.—A. Ladenburg.—The author agitates dilute aqueous solutions of an ortho-diamin hydrochlorate with an aldehyd, when the corresponding aldehydin is formed with liberation of heat.

Experimental Determinations of Position.—A. Ladenburg.—Not suitable for abstraction.

On Certain Phenyl-aldehydins.—A. Ladenburg and T. Engelbrecht.—An account of phenyl-benzaldehydin and phenyl-furfuraldehydin.

On the Aldehydins.—A. Ladenburg.—The author describes dibenzyliden-amido-benzoic acid; toluofurfuraldehydin, which latter body possesses an intense bitter taste recalling that of strychnin and acts upon animals as a powerful poison; and, lastly, phenyl-anisaldehydin.

Naphtho-picric Acid and Certain of its Derivatives.—T. Diehl and V. Merz.—The authors describe the preparation of this acid and the following of its derivatives:—Amido-diimido-naphthol hydrochlorate, the chromate of the same name, and the platonic double salt.

The Formula of Uric Acid.—H. B. Hill.—The author admits an error as to the original authorship of a structural formula.

Tetra-nitroxy-sulpho-benzide.—J. Annaheim.—This compound, $C_{12}H_6N_4SO_{12}$, is a solid, straw-coloured body, of an intensely bitter taste, melting at 253° , and deflagrating at higher temperatures.

On Mucobromic Acid.—O. R. Jackson and H. B. Hill.—An account of the preparation and of certain derivatives of this acid.

Analysis of the Mineral Spring Marienbrunnen, at Huckstalle, Westphalia.—H. Vohl.

Analysis of the Bitter Water of Rákóczy, from Buda.—H. Vohl.—The interest of these two papers, if any, is medical rather than chemical.

NOTES AND QUERIES.

Gluten in Grain.—Will any of your readers inform me what grain contains the largest amount of gluten?—E.

NOTICE.

MONTHLY ISSUE OF THE JOURNAL OF SCIENCE.

The JOURNAL OF SCIENCE will in future be issued MONTHLY instead of QUARTERLY, and will consist of 48 pp., the form and general appearance remaining the same.

The first of the Monthly issue will appear on
FEBRUARY 1st, 1879.

Price ONE SHILLING and SIXPENCE.

In addition to the usual articles on subjects of present scientific interest and reviews of scientific works, the MONTHLY JOURNAL OF SCIENCE will contain abstracts of papers read before the Scientific Societies—Reports on all Important Scientific Discoveries—A General and Critical Review of the Results of Biological Research—"Notes and Queries" and "Correspondence" Columns, &c., &c.

London: 3, Horse-Shoe Court, Ludgate Hill, E.C.

420 pp., Royal 32mo., French morocco, gilt edges, price 5s.

A POCKET-BOOK FOR CHEMISTS
CHEMICAL MANUFACTURERS, METALLURGISTS, DYERS, DISTILLERS, BREWERS, SUGAR-REFINERS, PHOTOGRAPHERS, STUDENTS, &c., &c. By THOMAS BAYLEY, Assoc. R.C. Sc. Ireland, Analytical and Consulting Chemist, Demonstrator of Practical Chemistry, Analysis, and Assaying, in the Mining School, Bristol.

Synopsis of Contents.

Atomic Weights and Factors—Useful Data—Chemical Calculation*—Rules for Indirect Analysis—Weights and Measures—Thermometers and Barometers—Chemical Physics—Boiling-points, &c.—Solubility of Substances—Methods of obtaining Specific Gravity—Conversion of Hydrometers—Strength of Solutions by Specific Gravity—Analysis—Gas Analysis—Water Analysis—Qualitative Analysis and Reactions—Volumetric Analysis—Manipulation—Mineralogy—Assaying—Alcohol—Beer—Sugar—Miscellaneous Technological Matter relating to Potash, Soda, Sulphuric Acid, Chlorine, Tar Products, Petroleum, Milk, Tallow, Photography, Prices, Wages, &c.

London: E. and F. N. SPON, 46, Charing Cross.
New York: 446, Broome Street.

CARBOLIC, AURINE, PICRIC, COLOURS AND TAR PRODUCTS.

A Chemist, with satisfactory testimonials as to Chemical Knowledge and Manufacturing Ability, with some years experience in the sole management of two Works, and full knowledge of business connection, &c., is open for an Engagement. To any gentleman with capital can offer good prospects of a very profitable return for money invested.—Apply, J. Longshaw, Penketh, near Warrington.

A Gentleman having had Six Years' Experience in Analytical Chemistry desires an engagement as Assistant, or as Chemist in Works.—W. H., Torwood Lodge, Fellatt Grove, Wood Green, N.

Manager of Tar and Ammonia Distillery will be disengaged on February 10, and will be open for Re-engagement. Advertiser has a good practical knowledge of the business, and is a steady energetic man.—Address No. 60, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Authors of "A Practical Treatise on the Manufacture of **SULPHURIC ACID,"**

with nearly 100 new illustrations (Sampson, Low, and Co., 188, Fleet Street, E.C.) are prepared to furnish plans and advice and superintend the erection of plant in all parts of the world.—Address, L. and L., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Situation wanted by a Competent Analyst as Assistant or Principal. Good teacher. Apply, Public Analyst, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, to exchange complete numbers of "Nature" for 1878 for complete CHEMICAL NEWS for same period, in good condition.—Apply to M., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, a Foreman in Superphosphate Works. Capable of undertaking the making of Sulphuric Acid and mixing. First class references required. He must be a married man. Apply to Edward Toynbee, Saxilby, Lincoln.

MANUFACTURING CHEMIST.

Wanted, a Young Man having a Good Know- ledge of Practical Chemistry. Must have been used to the Manufacture of Chemical Products.—Address, stating wages expected, experience acquired, and all particulars, to Chemist, care of Messrs. G. Street and Co., 30, Cornhill, E.C.

Water-glass, or Soluble Silicates of Soda and Potash, in large or small quantities, and either solid or in solution, at ROBERT RUMNEY'S, Ardwick Chemical Works Manchester.

WILLIAM AND WILLIAM T. FIELD,
MANUFACTURERS of the Celebrated **STAFFORDSHIRE BLUE BRICKS**, specially adapted for Chemical Plant, i.e., Acid Towers, &c. Also all other kinds of Best Staffordshire Blue Bricks, Pavings, Plyths, Splays, Copings, &c. &c. Prices and samples on Application.

TESTIMONIAL.

"We have used the Blue Staffordshire Brick for Sulphuric Acid Towers, &c., manufactured by Messrs. Field, for the last fifteen years, during which time they have given great satisfaction. We recommend them to the Chemical Trade, believing them to be nothing better in the market."—(Signed) WILLIAM HUNT and SONS, Lea Brook Alkali Works, near Wednesbury, Staffordshire, February, 1878.

TOLL END BRICKWORKS,
TIPTON, STAFFORDSHIRE.

THE NEW FASHION OF USING
at Home Dyes Prepared Free from Arsenic has not yet met with the appreciation it deserves. There is consequently still a great deal to be done before it will be properly introduced to the Public, by whom it is at present very little known, but by whom it could *easily be learned*, as it is so *practical* and *exceedingly simple in its application*.

I therefore now take the liberty to call attention to the under-mentioned advantages which this article offers for every household, and recommend it *strongly* to the Trade as an *easy selling and good paying thing*.

1. All my preparations are entirely free of poison, and possess a *very considerable intensity and beauty of colour*.

2. The dye preserves its different colours in wool, half-wool, cotton, and silk in a degree not yet attained by any other preparation.

3. The dye is made up in small packets of different colours, ready for sale, and in order to facilitate each colour being distinguished, every packet has the complete instructions how to use the dye printed on it in the same colour.

4. If kept in a dry place the preparations will keep for years.

5. The retail price of the packets is 3d. and 6d. each, but the following discount will be allowed :—

40 per cent to purchases amounting to 50s.
45 " " over 50s. and under 99s.
50 " " over £5.

TERMS CASH.

For the approaching Easter Festival I beg to recommend my EGG-DYES in different colours, such as ROSE, SKY-BLUE, YELLOW, ORANGE, and CARMINE.

They are *entirely free from Poison*, and of a splendid hue, in little packets with complete directions.

Price 1d. each, with equivalent reductions.

My preparations decidedly deserve the preference to all other articles of the kind as yet brought before the public notice, on account principally of their purity and brilliancy of colours, and as they are composed of only the best materials the colours are of unequalled intensity.

SAMPLES OF DYED WOOLS ARE TO BE HAD GRATIS OF

THE CHEMICAL NEWS.

VOL. XXXIX.

ON THE
3 FEB 79
ESTIMATION OF SMALL EXCESSES OF WEIGHT
BY THE BALANCE FROM THE TIME OF
VIBRATION AND THE ANGULAR DEFLECTION
OF THE BEAM.

By J. H. POYNTING, B.A., B.Sc.

WHILE working last year on an experiment to determine the mean density of the earth by the balance, I had to measure such an exceedingly small difference of weight, that I could not at that time estimate it by means of a rider, but was obliged to adopt the method described in this paper. Stated generally, it consists in treating the balance as a pendulum. Knowing the nature of the pendulum (that is its moment of inertia) and its time of vibration, we can calculate what force acting at the end of one arm of the beam will produce a given angular deflection. It is, in fact, an application to the common balance of the method which has always been used with the torsion balance when it has been necessary to calculate the forces measured in absolute measure. I cannot find any record of a previous application of the method, and as it might be of use in very delicate weighings, or in verifying the small weights in a laboratory, I have thought it worth while to give a full account of it.

When small quantities of the second order are neglected, and the oscillations are of the first order, it will easily be found that the equation of motion of the beam of the balance is—

$$(MI^2 + 2Pa^2\ddot{\theta} + (2Ph + Mgh)\dot{\theta} = a\ddot{\theta} \dots \dots (1)$$

Where MI^2 = moment of inertia of beam about central knife edge.

M = mass of beam.

a = half length of beam.

P = weight of either pan and the mass in it.

h = distance of line joining terminal knife edges below the central knife edge.

k = distance of centre of gravity of beam below central knife edge.

p = small excess in one pan.

θ = angular deflection in circular measure produced by p .

g = gravity.

If $\ddot{\theta} = \theta$ we have the position of equilibrium given by—

$$\theta = \frac{ap}{2Ph + Mgh} \dots \dots \dots (2)$$

The semi-periodic time is—

$$t = \pi \sqrt{\frac{MI^2 + 2Pa^2}{2Ph + Mgh}} \dots \dots \dots (3)$$

From equations (2) and (3) we can eliminate $2Ph + Mgh$, obtaining—

$$p = \pi^2 \frac{MI^2 + 2Pa^2}{ag} \frac{\theta}{t^2} \dots \dots \dots (4)$$

From this expression it appears that if we know the moment of inertia of the beam, its length, and the weight at each end, we can find the excess p from the time of vibration and deflection.

* Read before the Astronomer Library and Philosophical Society, December 29, 1878.

The results given in this paper were obtained with a 16-inch chemical balance by Oertling. The exact length of the half beam (a) measured by a dividing engine is 20.2484 centimetres.

To find the Moment of Inertia MI^2 of the Beam.—The simplest way theoretically would appear to be this. Find the times of vibration t_1 , t_2 and the deflections θ_1 , θ_2 due to the same excess p with two different loads P_1 , P_2 in each pan. Equating the values of p given for each by equation (4) we have—

$$\frac{MgI^2 + 2P_1a^2}{MgI^2 + 2P_2a^2} = \frac{\theta_2 t_1^2}{\theta_1 t_2^2}$$

An equation which will give MgI^2 in terms of known quantities. But on trial it was found that a very small proportional error in the observed time made a large error in the value of MgI^2 , and the following method, that usually adopted in magnetic observations, was employed in preference. A stirrup was suspended by a platinum wire, and its time of vibration (t_1) against the force of torsion (μ) of the wire was observed. The moment of inertia of the stirrup being S we have—

$$t_1^2 = \frac{\pi^2 S}{\mu}$$

The time of vibration (t_2) was then observed when a cylindrical brass bar of known moment of inertia B was inserted in the stirrup. We now have—

$$t_2^2 = \frac{\pi^2 (S + B)}{\mu}$$

The bar was then removed and the balance beam inserted in its place, and the time of vibration (t_3) gives—

$$t_3^2 = \frac{\pi^2 (S + MI^2)}{\mu}$$

From these three equations, eliminating S and μ we obtain—

$$MI^2 = \frac{B(t_3^2 - t_1^2)}{t_2^2 - t_1^2}$$

Now Bg was calculated from the weight and dimensions of the bar to be 6332.83 (in centimetres and grammes). The observed times were $t_1 = 3.6792''$; $t_2 = 4.495''$; $t_3 = 7.1483''$. From these values we find—

$$MgI^2 = 35651.6^*$$

To Measure θ .—The angle of deflection was measured by the number of divisions of the scale which the pointer moved over. As the length of the pointer is 32.1006 centimetres, while 20 divisions of the scale measure 2.5658 centimetres, a tenth of a division, in terms of which the deflection was measured, corresponds to an angle of 0.0003996. The oscillations were observed from a distance of 6 or 8 feet by a telescope. The resting-point (i.e., the point where the balance would be in equilibrium) was found in the usual way by observing the three successive extremities of two swings, and taking the mean of the second and the mean of the first and third. Five determinations of the resting-point were usually made with the excess to be measured alternately added and removed. From these five, three values of the deflection (π), due to the excess, were calculated in a manner which will be seen from the example below.

The Time of Vibration.—This was found from several determinations of the time of ten oscillations. The method will be seen from the example. No correction was needed for the resistance of the air as long as the vibrations did not exceed two divisions of the scale. When, however, they were much more than that the time of vibration was found to increase with the arc. As the time of vibration frequently changes slightly, probably through variations of temperature, it was usually observed before

* To this a small correction should be added if the adjusting bob is not in its lowest position. This amounts to 7.6 for each turn of the screw, and may therefore in general be neglected.

and after the determination of the deflection (n), and the mean of the two taken as the true time.

The following example of the determination of the value of a centigramme rider by placing it half-way along the beam will sufficiently explain the details of the method.

TIME OF VIBRATION AT COMMENCEMENT.

Pointer apparently Moving from Left to Right.

No. of Vibration.	Observed time of passage of pointer through resting-point.	No. of Vibratn.	Observed time of passage of pointer through resting-point.	Time of 10 Vibrations.
0	11h 15'36"	10	17'43"	127
2	16' 1"	12	18' 8"	127
4	16'25".5	14	18'33".5	127
6	16'52"	16	18'59"	127

Mean value of 10 vibrations 127

1	11h 15'49"	11	17'56"	127
3	16'14"	13	18'21"	127
5	16'39".5	15	18'46"	126.5
7	17' 5"	17	19'11".5	126.5

Mean value of 10 vibrations 126.75

Mean of means = 126.875.

$t = 126.875$.

DETERMINATION OF DEFLECTION n .

		92				
Added		152	53	102	66.75	35.25
		150				
Removed..		80	55	67.25	102.5	35.25
		79				
Added		147	60	103		
		145				

Mean value of $n = 35.83$.

TIME OF VIBRATION AT END.

Pointer apparently Moving from Left to Right.

No. of Vibration.	Observed time of passing of pointer through resting-point.	No. of Vibratn.	Observed time of passage of pointer through resting-point.	Time of 10 Vibrations.
0	11h 26'19"	10	28'27"	128
2	26'44".5	12	28'53"	128.5
4	27'10"	14	29'18"	128
6	27'35".5	16	29'44"	128.5

Mean value of 10 vibrations 128.25

1	26'32".5	11	28'39"	126.5
3	26'58"	13	29' 5"	127
5	27'23".5	15	29'30".5	127
7	27'49"	17	29'56".5	127.5

Mean value of 10 vibrations 127

Mean of means = 127.625.

$t_2 = 127.625$.

Remembering that one-tenth of a division of the scale is

an angle of 0.0003996 in circular measure formula (4), expressed in milligrams., becomes—

$$p = \frac{n}{t^2} 0.3996 \frac{\mu^2}{g} (MgI^2 + 2Pa^2)$$

In our present example—

$$n = 35.83$$

$$t = \frac{t_1 + t_2}{2} = 127.25"$$

$$MgI^2 = 35651$$

$$2Pa^2 = 24704^*$$

$$p = 5.724 \text{ milligrm.}$$

The length of time occupied in this determination was not quite a quarter of an hour.

The following table contains a series of results which I have obtained of the weight of two centigramme riders, the first of which was accidentally destroyed after the conclusion of the fourth determination. As the rider was always placed at division 5 on the beam, the values given in the table are double those actually obtained:—

No. of Expt.	$MgI^2 + 2Pa^2$	t in secs.	n	Weight of rider in milligrammes.	Mean Value.
1	145364	8.921	13.458	9.78	
2	309356	17.65	25.49	10.05

ON A NEW FORM OF APPARATUS FOR THE PRODUCTION OF FERROUS SALTS FOR TITRATION, &c.

By W. F. K. STOCK, F.C.S., F.I.C.

THE apparatus usually employed to procure the absence of atmospheric air during the solution of metallic iron in acids consists of a flask fitted with a cork, through which is passed a tube bent twice at right angles. When in use the free end of this tube is made to dip below the surface of water contained in a second flask or small beaker. The chief defects of this arrangement are:—

1st. Want of portability.

2nd. Necessity for some form of support for tube.

Having recently had occasion to execute a considerable number of determinations of metallic iron in samples of steel and iron, I constructed an apparatus entirely free from these defects, and very much more simple and convenient to manipulate. The following is a description of the new arrangement, which will be readily understood by the aid of the accompanying cut.

A is a flask of 200 c.c. capacity; B, a glass funnel 7 m.m. diameter; C, a glass tube of such a size as just to pass through stem of funnel B. D, an india-rubber joint connecting B and C and forming a perfectly tight joint; E, an india-rubber stopper, bored so as to pass stiffly upon C.

Perhaps a word upon the construction and use of the apparatus may be admissible. Having selected a tube of the proper size, the upper bend is turned on so that the point of the tube E, which should be narrowed to 1.5 m.m., falls into the apex of B. B is then placed in position and secured by D; the stopper E is next fitted on C, and finally the lower bend of C is turned on, taking care to allow so much tube as will prevent E being injured by heat.

* For this as for several other cases I removed the pans, and hung the weights directly by fine wires from the suspended pieces. By this means the resistance of the air was very much diminished.

In working the apparatus it is only necessary to place sufficient water in *s* to cover end of *c*, in order to secure exclusion of air. The most certain source of heat is a sand-bath. Using this I have never had a case of untimely regurgitation. Immediately the required solu-

tion is effected, the apparatus is removed from the source of heat, and recently-boiled water is run into the funnel *s* to the required extent.

Laboratory and Assay Office, Darlington,
January 22, 1879.

THE SEVEN FUNDAMENTAL TYPES OF ORGANIC CHEMISTRY,

AS VIEWED AND INTERPRETED FROM THE STANDPOINT
OF THE "TYPO-NUCLEUS" THEORY.

By OTTO RICHTER, Ph.D.

(Continued from p. 39).

In order to enable the reader to comprehend the full theoretical import and significance which attaches to this hypothesis of seven fundamental types, it becomes necessary for me to direct his attention to that most complex and elaborately finished specimen of molecular architecture in which the whole of our seven types are supposed to be collectively and completely represented, and to join me in a rapid survey of its general internal structure and organisation. Let it first of all be distinctly understood that in this our model-molecule, which relatively to the three conjugate axes of space is held to exhibit the most perfect symmetry of form and atomic arrangement, the primary constituent groups are placed side by side along the whole extent of one of these axes, to which I shall henceforth apply the term "Operative Axis," because it coincides with the particular line or direction in which chemically conflicting molecules are invariably brought to attack and to react upon each other. Let all this be taken for granted, and we may readily conceive the practicability of a mode and order of grouping, wherein our seven fundamental types have each one allotted to them a certain definite portion of space, within whose limits the primary groups are symmetrically distributed in obedience to their own special laws of molecular collocation and arrangement. It is further argued that the seven portions of space just alluded to, and which in their collective capacity may not inaptly be compared to a suite of continuous closets or chambers, are each of them destined

to serve as repositories for the exclusive accommodation of that particular class of molecules only which bear upon them the stamp of the presiding fundamental type. It is upon the basis of this, to my mind, perfectly natural and reasonable hypothesis that I shall now proceed to expound the main features of this wonderfully simple, yet all-accommodating seven-chamber system, with the view of determining not only the exact relative position of each chamber in our model molecule, but likewise what are the most salient chemical properties and functions with which its respective occupants are more or less liberally marked and endowed.

Commencing with the middle chamber, and bearing in mind that in my system the principal nucleus is invariably regarded as forming the common central point of attraction, towards which all the other component groups are, directly or indirectly, made to tend and to gravitate, it stands to reason that this identical nucleus is justly entitled to become the chief and only occupant of this middle chamber. The middle chamber, which is thus shown to claim for itself a prominently central position, is supposed to be flanked on the one side by the outer conjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular class of molecules which were formerly described by me as components of the envelope, but for which the more appropriate term "outer conjunct molecules" will henceforth be substituted. Again, the middle chamber is supposed to be flanked on the other side by the inner conjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular class of molecules which were formerly described by me as hydrocarbon adjuncts, but for which the more appropriate term "Inner Conjunct Molecules" will henceforth be substituted. Continuing our survey, the outer conjunct chamber is supposed to be flanked by the outer subconjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular set of substituted constituents which, from their chemical character and composition, are denied free admission into the outer conjunct chamber. Again, the inner conjunct chamber is supposed to be flanked by the inner subconjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular set of substituted constituents which, from their chemical character and composition, are denied free admission into the inner conjunct chamber. Completing our survey, the outer subconjunct chamber is supposed to be flanked by the outer adjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular class of co-ordinately allied poly-basic and poly-acid molecules, whose parent molecule is above poly-atomic alcohol, while the inner subconjunct chamber is supposed to be flanked by the inner adjunct chamber, which I hold to be reserved for the exclusive accommodation of that particular class of subordinately allied poly-basic and poly-acid molecules, whose parent molecule is a pseudo-poly-atomic alcohol.

Having now, with the aid of our model molecule, submitted to the reader a tolerably complete general outline of the internal structure and organisation of every conceivable variety and complexity of chemical combinations, strictly so-called, I shall in the next place endeavour to explain to him the precise nature and efficacy of those three fundamental agencies or principles which are supposed to over-rule and set in motion the wonderful mechanism with which this magnificent heptarchical system of types has been so knowingly and sapiently furnished.

Commencing with the nucleus type, I proceed upon the very simple and intelligible hypothesis that all the members of this class are formed by the direct union of two chemically identical but physically dissimilar elementary molecules, E_2 , and that these physical differences, supposed to be due to certain variations in the vibratory movements of their constituent atoms, are held to constitute an efficient cause for their coalition into a molecule of double the atomic weight. The class of molecules before us will, therefore, be expressed by the general symbol $2E_2$; and

it is of importance to bear in mind that the two thus firmly welded and interlaced molecules have now as a whole become endowed with sundry very marked and tangible chemical properties and functions.

Turning from this to the second or outer conjunct type, it is conjectured that all the members of this class owe their origin and formation to the union of two not differently but similarly modified elementary molecules, E_2 . These molecules will therefore likewise be expressed by the general symbol $2E_2$; but from the peculiar conditions of their generation, which invariably require the presence and co-operation of an over-ruling nucleus, it follows that, whereas the nucleus molecules possess in a high degree the character of consistency and stability, the outer conjunct molecules are, on the contrary, entirely destitute of these qualities. Hence it becomes impossible for them to exist apart from the dominating nucleus, to which alone they are indebted for their seeming firmness and ready associability. It is clear, therefore, that, in the act of being withdrawn from under the constraining influence of that powerful centre of attraction, the liberated molecules will instantly become re-converted again into molecules of the nucleus type, from which they are understood to have originally sprung, or else into molecules of the inner conjunct type, provided always that the chemical nature of their constituent atoms is not opposed to this species of molecular metamorphosis. It is, moreover, worthy of note that, while and so long as the molecules under consideration continue to subsist in the aforesaid compulsory state of bondage and confinement, they seem to be destitute of any special chemical properties and functions, whereas these same molecules, after their conversion into the corresponding subjunct molecules, are destined to play a very prominent part in the molecular economy by co-operating with the principal nucleus towards the proper conduction and consummation of that identical process of molecular substitution which, as already pointed out on a former page, became so unduly magnified and so unwisely selected by our leading theorists as an all-sufficient ground for the erection of a solid and comprehensive chemical theory.

As regards the inner conjunct type, which falls next to be considered, I have come to the conclusion that all the members of this class require for their realisation the joint action of neither more nor less than four primary and chemically identical hydrocarbon molecules, as expressed by the general formula H_2pC_2q (p and $q = 0, 1, 2, 3, 4$, &c.), a formula which is seen to include likewise the exceptional cases, when pure hydrogen or pure carbon are made to play the part of inner conjunct molecules. The cementing agent is again believed to be the physical principle which, by causing one of these molecules to become differently modified from the remainder, determines their coalition into one single and four times heavier molecule with the general formula $4H_2pC_2q$. I may observe, in addition, that the resulting simple hydrocarbon molecules share with those of the nucleus type the character of great consistency and stability, while, in complete analogy with the members of the outer conjunct type, these same hydrocarbon molecules, from the simplest to the most complex, are capable of entering into direct chemical union with a given principal nucleus, no matter whether that nucleus happens to be presented to them from without, or whether, as is frequently the case, it has first of all been moulded out of one or other of their own component hydrogen or carbon molecules. A second very striking and remarkable feature which the inner conjunct molecules share with those of the outer conjunct chamber consists in the circumstance that, thanks to their direct chemical union with a principal nucleus, the component hydrogen and carbon molecules have now acquired the singular power and faculty of co-operating with the said nucleus towards the proper conduction and consummation of that identical process of molecular substitution to which—I repeat it with emphasis—the founder of our modern school of philo-

sophy most wrongfully insisted upon attaching such an undue weight and preponderance.

As regards the two types which follow next in the list, namely, the outer and inner subjunct types, their origin and mode of formation have already to a certain extent been traced and foreshadowed in my closing remarks on the preceding types. The presiding agency is supposed to be the principle of calority or thermal principle, and the entire process of molecular substitution, which is the outcome of the practical application of that principle to molecular statics and dynamics, will be best understood from a descriptive analysis of its three principal stages. In the first stage, the particular outer or inner conjunct molecule which is destined for conversion in the corresponding subjunct molecule is first of all made to part company with the principal nucleus, and becoming instantly subjected to the powerful influence of the ever-present physical principle, it is speedily brought to remerge under the more permanent typical form of an ordinary nucleus. In this act of dissociation the newly generated subjunct molecule is supposed to move away from the principal nucleus, without, however, passing beyond the critical point where, at a high temperature, the simultaneously formed thermal bond, as I will call it, and which is now destined to serve as the only cementing link between the principal nucleus and its similarly constituted subjunct, becomes suddenly and forcibly torn asunder. It is, of course, impossible to determine *a priori* the exact number and degree of elasticity of the various kinds of thermal bonds by means of which subjunct nuclei may remain attached to their principal nucleus. There exists, however, abundance of valuable experimental evidence to prove that in this first stage of the process certain outer subjunct nuclei, like chlorine and its congeners, remain attached to the principal nucleus by means of one thermal bond only; others, again, like oxygen and sulphur, by means of two thermal bonds; while a third class of outer subjunct nuclei, like nitrogen and phosphorus, remain attached thereto by means of three thermal bonds, that being the highest number, so far as my system is concerned, which suffices for the complete elucidation and analysis of this interesting and instructive order of chemical phenomena. There exists, moreover, abundance of valuable experimental evidence to prove that inner subjunct nuclei with hydrogen for their component element remain attached to the principal nucleus by means of one thermal bond only; while subjunct nuclei, with carbon for their component element, remain attached thereto by two thermal bonds, and not at all by means of four thermal bonds, as is still persistently taught and maintained on the other side.

(To be continued).

THE CULTIVATION OF CHEMISTRY.*

By F. W. CLARKE, B.B.,
Professor of Chemistry in the University of Cincinnati.

ONCE a year it is our pleasure and our privilege to meet together, for the interchange of views upon the questions of chemical science; for the comparison of notes in our various lines of research; for mutual help, sympathy, and improvement. It is also, I suppose, a part of our work to attract public attention to the subjects that interest us, and to do what we can to secure for chemistry a wider appreciation and greater means for development. No branch of science has done more for civilisation than ours. Old industries have been revolutionised, and new ones created; things which were once the luxuries of the few have been made the daily necessities of the many; all arts and all manufactures owe tribute to the chemist. A comparatively small number of men, a majority of them

* Address before the Permanent Sub-section of Chemistry of the American Association for the Advancement of Science, at the St. Louis Meeting, August, 1878.

teachers, working only in their intervals of leisure, established the principles which have brought about these wonderful results. If small means, widely scattered and unsystematically used, have wrought such marvels, what may we not expect from the greater opportunities which a more general comprehension of the value of our labours must eventually bring?

To the members of this sub-section, the economical achievements of chemistry are familiar as household words. As we look about us in our daily lives, we see in every direction the fruits of chemical investigations. Every scrap of metal; all paints, varnishes, fats, oils, and fertilisers; every bit of glass or porcelain; every cake of soap or box of matches, embodies some improvement which chemistry has made. Our linen is bleached and our outer garments are dyed with the products of the laboratory. Whether we burn candles, gas, or kerosene, we still have chemistry to thank for nearly all there is of cleanliness, convenience, brilliancy, purity, and cheapness in the light. In many articles of food, and in a long list of medicines; in the photograph and the galvanic battery; by the conversion of waste rubbish into articles of beauty and usefulness; in short, through a vast network of improvements and discoveries, our still infant science has established its claims to recognition as a benefactor of mankind. Would that the multitudes who have enjoyed these benefits might see their sources as clearly as we do! Then would science be fostered and encouraged, where now it struggles feebly to secure a grudging and scanty support.

A single discovery of the chemist may work peaceful revolutions in many departments of labour. Pardon me if I pause to illustrate this truism by a very familiar example. Even for us it is not a waste of time to look backward occasionally, and to consider the consequences developed from one great research or invention. Such considerations may well strengthen us in our hopes for the future of chemistry.

Nearly ninety years ago, Le Blanc discovered his famous process for converting common salt into soda. No process could be much simpler than this, and yet in its ramifications it has affected every branch of civilised society. In the first place, it widened the field of labour. Certain materials were needed at the start, namely: salt itself, charcoal, limestone, and sulphuric acid; and many workmen found employment in their production. By the new demand for sulphuric acid, this important compound was rendered cheaper, and every other chemical industry was thus directly facilitated. If the familiar saying be true that the degree of civilisation to which any country has attained may be measured by the amount of sulphuric acid it consumes, then the importance of this single item can scarcely be over-estimated. Passing from the materials employed to the process itself, we find that incidentally, as a by-product, it furnishes immense quantities of hydrochloric acid at a minimum of cost, and that here again all branches of manufacturing chemistry receive direct benefit. As a final result—if, indeed, any result can properly be called final—we find that the soda, for which the process was devised, has been enormously cheapened. In 1814, soda crystals were worth about 300 dols. per ton. By 1861, the price had fallen to 22 dols.; 5000 tons a week were produced, and 10,000 labourers found direct employment. This does not include the labour engaged in furnishing materials for the process, nor that incidentally stimulated through other industries. By the cheapening of soda, other things of more generally familiar utility were cheapened also. Chief among these we may mention glass and soap, two articles in which soda is a leading ingredient. Such a reduction in the price of soda as that just indicated could not but work wonders here. As glass and soap became cheaper, the demand for them naturally increased; and hence, through Le Blanc's invention, our houses are better lighted, cleanliness has been encouraged, and the public health, because of these steps forward, has unquestionably been improved.

In short, the results of this single invention, direct and indirect, can be traced into nearly every department of human industry. These results have been exclusively beneficial. All of us share in their advantages, and no one has been injured. They have given employment to many thousands of labourers, and that without prejudice to older occupations. And thus it is in some degree with every discovery of the chemist. Each one is like a grain of corn, small in itself, and yet a germ from which may spring the food of numberless future generations. In the course of our labours, many grains may fall by the wayside and bring but small return; still, that which sinks into fertile soil will yield a thousand fold reward to the sower.

I need build no argument upon the facts I have just given. They stand before us, not only on the pages of books, but embodied in countless manufactories scattered all over the civilised world. They render life pleasanter, easier, more comfortable. They are the sources from which future discoveries shall flow, and help to make certain the steady growth of civilisation. If the general public is not interested in chemistry, it is because we as chemists have neglected a part of our duty. We have but to speak in order to command the public ear. Our work is work of national importance, and is sure in time of national recognition. Let us ask ourselves to-day how the splendid achievements of the past may be made more fruitful, and what measures and what researches will best advance the interests of our science in the future.

It is safe to assert that in every science there is some central line of growth, to which all details are subordinated, and along which its fundamental principles find their readiest and most logical development. Here lie the germs of future generalisations; whatever promise there may be of greater exactness, either in methods or in data; and all those deeper conceptions which most intimately connect a given science with other branches of thought and knowledge. Without such a main stem, each science would be but a mass of scattered details, isolated facts, fragmentary principles, with little coherence or order. True, we may fail to recognise a real line of growth, or we may follow a false clue, and yet make discoveries of great value; but without clear ideas upon this subject the highest work is impossible. In physics, the doctrines of the conservation of energy and the correlation of forces are points on the central line. In the study of organised life, the theory of evolution indicates a main stem. How is it with chemistry?

Among chemists to-day there seem to be two schools; at least practically, if not in point of abstract theory. It is almost as if the line of growth had divided, so that we can hardly tell which is the greater, and which the lesser stem. One school, represented by a large majority of modern working chemists, seems to take an interest only in the statical side of the science; its chief aim is to discover immense numbers of new compounds, and to theorise upon their constitution. Strangely enough, these chemists have devoted nine-tenths of their energy to the compounds of a single element, carbon; scarcely regarding other substances save in so far as they unite with this or with bodies containing it. To me it sometimes seems as if, in the light of their labour, chemistry was to be defined as the science of speculating upon the possible position of theoretical atoms within imaginary molecules. Do not think, however, that I undervalue the value of the work they have done. I fully recognise its importance, although I consider it unfortunate that so much time and energy should have been spent in this one line of research, to the neglect of other, and I believe greater, fields of investigation.

The other school of chemists, a school which seems to be rapidly growing in England and to be gaining industrious votaries elsewhere, may be described as essentially dynamical in its ideas. It sees in every chemical reaction three objects of study: first, the substances which enter into the reaction; secondly, the phenomena which occur during the reaction; thirdly, the substances produced

by the reaction. The second term, the term which involves all the transformations of energy, is to them of at least equal importance with the others. In this they study the play of forces attendant upon the formation and destruction of compounds, the appearance or disappearance of heat, the velocity of the change, the effects of pressure, the alterations in volume, and so on. To them, every element and every reaction is important and interesting; they strive to see each change of composition in all its relations; to study processes as well as results; to recognise the intimate connection between chemistry and other sciences. Does it not seem as if these workers were pretty nearly on the right track? Is not their method of study the deepest and broadest? Does it not really include all there is of permanent value in the other school? To me, at least, it seems as if here the great advances are to be made, and the central line of growth discovered.

This feeling is justified, I believe by history. Much of the best progress in chemical science has been made on the physical side. In truth, chemistry and physics are but one at bottom, having their roots in the same fundamental principles. Electricity cannot be studied apart from chemical considerations, neither can light nor heat. Nor are we able to understand truly a chemical operation until we know a good deal about the physical forces which it necessarily involves. Neither science can be mastered apart from the other; for they are but two great branches from one common line of growth. The molecular theory, without which modern chemistry could hardly have existed, rests mainly upon physical foundations. Apart from the laws of Avogadro and Ampère, of Dulong and Petit, of Boyle and Mariotte, of Gay-Lussac and Charles, much which is now plain and orderly to the chemist would be chaotic and unmanageable. Doubtless, at some future time, the investigations of Mitscherlich and others into isomorphism, of Kopp into molecular volumes, of Thomsen and Berthelot into thermo-chemistry, of Gladstone into refractive indices, of Harcourt and Eason, and Boguski and Kajander into the velocity of chemical changes, will lead to generalisations of equal importance with these. The workers I have named, with many others equally worthy of naming, have already done enough to give us glimpses of great laws which we are as yet unable to see in their entirety. These glimpses forward are like promises made by Nature; sometime to be fulfilled, certainly never to be broken. Were we to take from chemistry all that has been done upon the physical side, how little true science would remain! We should have left but little law and little order; scarcely more than a vast mass of scattered facts and details, unconnected with any fundamental conceptions or any definite method of scientific research. Physics, stripped of its chemical portion, might make a somewhat better showing; but even then it would be little more than a skeleton of what it now is. Neither science can be strong without the other.

One of the main objects of science is to render prevision possible. The more thoroughly our knowledge is co-ordinated, the better are we able to predict the nearer discoveries of the future, and to see what lines of research will be most fruitful. Science is continually striving after exactness; of which this prevision is one of the results. The line, therefore, which leads most directly to definiteness and precision in any department of knowledge, is evidently the true line of growth which we should seek to find and to follow. Nature marks out pathways for us, even though we close our eyes to her indications.

To-day, notwithstanding its brilliant achievements in the past, chemistry is an inexact science. From top to bottom, from beginning to end, it shows signs of imperfection. Indeed, to most minds, this incompleteness is a great charm. There is so much to be done in chemistry, so many lines of research to follow out, so many discoveries to be made, so much glory to be won and good to be accomplished, that an active mind can hardly fail of being attracted. We may well feel, with the German

philosopher, that the power to search after truth is more precious than truth itself. Were it possible for any science to become absolutely perfect, we should but idly fold our hands and enjoy its fruits, caring little for the history behind us, or for a future which could bring us nothing more. Perhaps, in the beneficence of Nature, we might even lapse into forgetfulness, in order that our descendants could enjoy the pleasure of a re-discovery. Speaking simply in a relative sense, chemistry is an eminently imperfect science. In experimental resources it is wonderfully rich; in delicate methods of investigation no other science can surpass it; but in those principles which render foresight possible, chemistry is poor and meagre. We may guess the existence of some undiscovered compound, but until we have prepared it what can we tell of its properties? A little perhaps, a very little; and that only approximately. Of its relations to the great forces of Nature, we know in advance almost nothing. We are able only to devise for it some "structural formula" which shall last for about five years, and then be replaced by another of equally perishable quality. We are, in fact, to-day but laying the foundations of a future science, which shall be to the chemistry of the present what that is to the alchemy of the past. What the chemist has already done for humanity has been done in spite of difficulties and defects; it is but a trifle compared with that which shall be accomplished in the better time to come. Enough has been done to prove the possibility of more; to encourage the investigator in his labours; to show the public that here is something worthy of study, of help, and of applause.

There are three great objects of investigation in chemistry as seen under its present aspect; three central problems upon which all else depends. First, what laws govern the transformations of energy that occur during chemical changes? Second, how do the properties of compounds stand related to those of the elements contained in them? Third, what is the nature of chemical union? These problems must be studied largely together; each one in the light of the other two. The first and second, however, are more practical in character than the third, and involve less speculation. They need for their solution severe experimental researches, the exact determination of numerical data, and reasoning of a rigidly mathematical kind. Under the third problem we encounter the chief speculations of chemistry, hypotheses which serve to suggest and stimulate investigations with regard to the other two, while at the same time dependent upon these latter for the security of their foundations. The nature of the elements, whether one or many; the truth or falsity of the atomic theory; all questions of inter-molecular structure; the validity of certain formulæ; the value of such doctrines as that of quantivalence; these are the ideas with which this problem has to do. Each one of these theoretical questions is but a special case depending for its answer upon our views concerning the main point of all. Plainly, the first thing for chemistry to do is to make sure of its foundations; using speculation only as a line by which parts of the work may possibly be helped and guided.

The only foundations which can stand the test of time, in such a science as ours, are exact, rigorous, quantitative measurements. We already know tolerably well in a qualitative way what transformations of energy occur in chemical changes; the question now is as to their definite numerical relations. How much heat appears or vanishes in any given reaction? what is the exact electromotive force of any specified couple? what laws of quantity connect actinic energy with particular combinations or decompositions? These are the questions which science now asks, and for which in a few cases we are just beginning to find answers. The physicist approaches these questions from one side, the chemist from another; eventually the two will meet, and a general solution will be found. From our knowledge of forces on the one hand, and of substances on the other, we shall become able to compute

the dynamical relations of every possible chemical change, and perhaps even to determine in advance what reactions can and what cannot take place.

(To be continued)

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

January 25, 1879.

Professor G. C. FOSTER, Vice-President, in the Chair.

PROF. E. RAY LANKESTER and Mr. Alex. Macdonald, B.A., were elected members.

Dr. ERCK exhibited a constant bichromate of potash battery. The ordinary bichromate battery soon loses power when in use, and in order to secure a powerful constant battery to drive a small astronomical clock, Dr. Erck devised the modified form shown. It consists of a narrow lead trough, 12 ins. long by 3 ins. wide and 1 in. deep, lined along both sides with the carbon plates. The zinc plate, 10 ins. long, is immersed in the solution to the depth of an inch midway between the two carbons. A continual circulation of the bichromate solution is kept up by allowing fresh solution to drop into the cell at one end, and the exhausted solution to drop away by a tap at the other end. As the space between the two carbons is only about half an inch wide, there is merely a thin layer of solution between the positive and negative poles. The internal resistance of the cell is therefore very low when short circuited, only about $\frac{1}{2}$ ohm. To obtain the maximum current, about 8 ozs. of solution per hour should be supplied. Dr. Erck also showed a battery formed of zinc and carbon circular plates mounted on an axle, which is rotated by wheelwork, thus mechanically stirring the bichromate solution.

Dr. GUTHRIE, F.R.S., described some the results he had obtained from experiments on the vibration of metal rods or lathes fixed in a vice at one end and free to vibrate at the other. The experiments were carried on by dusting sand on the rod and observing the nodal lines formed by it when the rod was vibrated so as to give out notes determined by a monochord. Dr. Guthrie's results showed that the two final segments at the free end are equal in length to the inner segment at the fixed end. It appears from these experiments that if a free lathe, vibrating with a node in the middle but having an even number of segments, be clamped at where there is a node we alter its conditions of vibration. When the lathe is half free the end segment breaks up into two parts together equal to the segment at the fixed end. In the case of torsional vibration of the lathe the position of the longitudinal nodal lines depended to some extent on the clamping of the lathe in the vice.

Prof. FOSTER pointed out that in a natural node the direction of the tangent is varying, whereas in an artificial node it is always horizontal.

Prof. UNWIN explained that the sand accumulated at nodes because the particles when thrown off the lathe make certain horizontal excursions, which tend to move them nearer the points of repose of the lathe.

Messrs. Elliot Brothers exhibited sundry electric commutators and resistance boxes.

EDINBURGH UNIVERSITY CHEMICAL SOCIETY.

Third Meeting, January 15, 1879.

Mr. G. CARR ROBINSON, F.R.S.E., in the Chair.

A PAPER was read by Mr. J. ADRIAN BLAIR, B.Sc., on the "Salts of Trimethyl-sulphine," containing further

results of an investigation carried on by Prof. Crum-Brown and the author.

The decomposition product of the hyposulphite of trimethyl-sulphine (CHEMICAL NEWS, vol. xxxvii., p. 130) was found by analysis to be represented by the following equation:—

The methyl-hyposulphite of trimethyl-sulphine thus obtained is very hygroscopic, and is gradually oxidised to a sulphate. The solution of the substance does not decolourise iodine solution. These results point to—

as the probable rational formula of the substance.

The sulphite of trimethyl-sulphine was obtained by the action of sulphurous acid on the hydrate. It crystallises well, but there is some difficulty in preparing a perfectly normal salt. The salt, as nearly normal as possible, does not, like the hyposulphite, give up its water of crystallisation in the cold over anhydrous phosphoric acid; at 140° C., however, it becomes anhydrous. Heated to 175° C. it gives off sulphide of methyl—8.3 grms. lost 2.32 grms., or 27.95 per cent. On cooling, the clear liquid residue solidifies, forming a hard, very hygroscopic, crystalline mass. This substance was so deliquescent that no analysis of it was made. This mode of formation leads to—

as its most probable formula.

In order to ascertain the nature of this substance the authors converted it, by double decomposition with iodide of potassium, into the corresponding potash salt, which was purified from the iodide of trimethyl-sulphine by crystallisation—

This potash salt was found to agree in properties and composition with the "sulpho-metholate" or "methyl-sulphonate" of potash.

The bearing of this fact on the constitution of mephites is obvious.

The acetate of trimethyl-sulphine is formed by treating the iodide of trimethyl-sulphine with acetate of silver.

On leaving the strong solution over sulphuric acid *in vacuo* for three weeks no crystallisation took place. The strong solution on being heated to 100° decomposed into water acetate of methyl and sulphide of methyl.

The benzoate of trimethyl-sulphine is formed by treating the iodide of trimethyl-sulphine with benzoate of silver,

This salt is very soluble in water. On standing for two weeks over sulphuric acid *in vacuo* only a very few crystals were formed, which it is difficult to separate from the very thick mother-liquor. It is slightly less soluble in alcohol. The imperfectly dried salt on being heated to 110° decomposes into water, benzoate of methyl, and sulphide of methyl.

The dithionate of trimethyl-sulphine is obtained by neutralising an aqueous solution of dithionic acid with

the hydrate of trimethyl-sulphine. On evaporating the solution of the salt on the water-bath it begins after a time to crystallise out. On leaving the saturated solution to cool a large quantity of clear cubical crystals were obtained. These are not hygroscopic, insoluble in hot alcohol, and without any smell of sulphide of methyl. These properties prove it to be one of the most stable of the salts of trimethyl-sulphine. Analysis agrees with the formula—

On heating the salt to about 120° water is given off. On raising the temperature to 220° sulphurous acid is given off, and afterwards along with it sulphide of methyl, and the salt froths and melts. The heating at about 200° was continued until very little gas was given off. 8·015 grms. were found to have lost 3·325 grms., equal to 41·4 per cent. On cooling the liquid solidified. The crystalline mass was very hygroscopic, and dissolved in alcohol. On adding ether to the alcoholic solution the substance was precipitated as an aqueous syrup, and on standing over sulphuric acid crystallised out in beautiful long fine prismatic needles. The presence of the trimethyl-sulphine radical was proved by double decomposition with iodide of potassium, when the iodide of trimethyl-sulphine crystallised out. The presence of methyl-sulphuric acid was also proved. These results, along with estimations of carbon and hydrogen, prove the substance to be the methyl-sulphate of trimethyl-sulphine. The decomposition of the dithionate is therefore expressed by the following equation:—

A paper was also read by Mr. J. W. DRAKE on the "Constitution of Inorganic Salts."

NOTICES OF BOOKS.

Useful Information on Practical Electric Lighting. By KILLINGWORTH HEDGES, C.E., M.I.M.E.

A POPULAR account of the principles, production, working, and in part the cost of the electric light, confessedly somewhat hastily thrown together. Mr. Hedges divides his subject into nine sections. The introduction treats of the laws governing induced magnetic currents; the second chapter of the various kinds of electrodes and electric lamps; the third is on the division of the electric light. The kind and quantity of power required are considered, as well as the application of the light for illumination. The transmission of electricity by wires is then explained, the approximate cost of working is necessarily somewhat incompletely dealt with, trustworthy data being as yet wanting. Mr. Hedges, speaking as a practical engineer, very properly ridicules the nonsense that has been written respecting the extinction of gas by electricity. The same prophecies were made with regard to oil and candles when first gas was used. The electric light, says Mr. Hedges, will educate the public to a higher degree of artificial lighting, a prophecy already fulfilled by the Phoenix Gas Company, which has lighted up the bridge end of Waterloo Road with a brilliancy hitherto unknown in the history of gas lighting. A higher standard of gas will be called for by shopkeepers, and an increased, instead of a diminished, consumption of gas will follow. We cannot, however, agree with Mr. Hedges when he thinks that we may obtain the electric light more economically from the battery than from the dynamo-electric machine. Mr. Hedges promises to give us a second edition of his pamphlet. In the present edition he has been continually betrayed into the use of technical expressions which, although perfectly familiar to all scientific men, will be simply so much Sanscrit to the ordinary reader.

Catalogue of Chemical Apparatus and Pure Chemicals Sold by Townson and Mercer, 1879.

A WELL compiled illustrated catalogue of every description of chemical and physical apparatus. We would especially direct the attention of students, teachers, lecturers, and medical officers of health to the cheap sets of scientific apparatus described at the end of the book, which seem to be a speciality of this old-established firm. There is an excellent index at the end of the catalogue.

Practical Physics, Molecular Physics, and Sound. By FREDERICK GUTHRIE, Ph.D., F.R.S.S.L. and E., Professor of Physics in the Royal School of Mines. London: Longmans and Co., 1878.

THIS little work belongs to the excellent elementary series called the London Science Class Books now in course of publication by Messrs. Longmans. The arrangement adopted by Prof. Guthrie is somewhat new. After explaining the principles of molecular cohesion in the case of solids, liquids, and gases he carries his pupil through diffusion, effusion, osmose dialysis, and vortex motion, into wave motion in general, and lastly introduces him to the principles of sound, thus rendering the sequence complete, the string telephone and the phonograph being introduced as illustrations. There is a useful appendix added explaining the use of the vernier, the method of making parchment paper, hints on glass working, barometer making, &c. The experiments illustrating the lessons in the body of the work, and the apparatus and materials used in performing them, are also explained at greater length in a second appendix.

Notes of Statutes and Legal Decisions Affecting the Public Health Act, 1875, from 1875 to 1878. By J. V. VESSEY FITZGERALD, B.A. London: Longmans and Co.

THESE notes are intended by the author as a sequel to a former work on the same subject at the time of the passing of the Public Health Act of 1875. To officers of health, inspectors of nuisances, factory inspectors, medical men, local boards, vestries, and all other bodies or individuals whose duty it is to see that the provisions of the various health acts are duly carried out, this little work will prove invaluable.

The Retrospect of Medicine. Edited by W. BRAITHWAITE, M.D., and JAMES BRAITHWAITE, M.D. Vol. lxxviii., July to December, 1878. London: Simpkin, Marshall, and Co., 1879.

AS usual there is but little to interest the chemist in the present volume of Braithwaites' "Retrospect," valuable as it may be from a purely medical point of view. A Dr. Jencken, who hails from the Emerald Isle, recommends gun-cotton as a dressing for wounds on account of the antiseptic character of the acids used in preparing it. We should imagine that properly washed pyroxylen would have no greater antiseptic power than ordinary cleaned cotton-wool, while if it still retained sufficient traces of acid to possess antiseptic properties it would be a highly dangerous addition to hospital requisites. Of quite a different calibre is Mr. Spencer Wells's warning to surgeons—not too place to much confidence in the use of antiseptics in surgical operations at the risk of omitting any of the precautions which experience has declared to be necessary; in a word, antiseptic treatment must not be looked upon as a substitute for measures which have already proved effectual, but only as an additional safeguard. Sir Henry Thompson gives an account of the use of the microphone in sounding for stone (July, 1878), but his experiments at present do not seem to have led to any practical result. The use in psoriasis of crysophanic acid, one of the few chemical remedies discovered of late years, appears to be spreading. By the way, we may mention that a cheap method of preparing this acid

is a desideratum. It is related to anthracen, being convertible into that substance when heated with zinc-dust, the contrary operation, therefore, ought not to be impossible. The only other papers of chemical interest are those of Dr. Ogston, Jun., "On a Stale Solution of Ammonium Sulphide as a Test for Chloral; "On Butyl-chloral," by Liebreich, who finds that whereas in the case of ordinary chloral hydrate the heart is paralysed before the respiratory organs, the reverse held good in the case of butyl-chloral, a very singular and important physiological observation; and "On the Advantage of Oxygen Inhalation in Cases of Asphyxia from Breathing Carbonic Acid." Dr. R. H. Goolden announces that for thirty-five years he has used manganese sulphate with great success in the treatment of liver complaint, but that a prejudice exists against its use on account of the difficulty of getting it dispensed, pharmacutists either never having the salt in stock or taking manganese sulph. for magnesiae sulph., and dispensing it accordingly. Dr. Goolden's efforts to introduce this remedy deserve all praise, in spite of the little success that he has hitherto met with. The same remark applies to Dr. B. W. Richardson's endeavours to introduce the alkaline ethylates as caustics.

CORRESPONDENCE.

INFLUENCE OF CHLOROFORM ON NITRIFICATION.

To the Editor of the Chemical News.

SIR,—In reply to Mr. Warrington's letter, I must at once acknowledge that I used the term "nitrification" in a stretched and, I fear, erroneous sense. I certainly am of opinion, that in many cases "the destruction and production of nitrates are allied phenomena, both of which are due to the action of bacteria" or of similar organisms. Perhaps even one and the same organism induces both the formation and (under different circumstances) the reduction of nitric acid, and both these actions I included in the term "nitrification," precisely as we consider both the decomposition and the formation of carbonic acid by plants as evidences of the growth of the plant, although in reality the excretion of carbonic acid is rather a sign of decay than of increase.

When I stated that nitrification was not arrested by small quantities of chloroform I meant, and ought to have said more clearly, that chloroform is not necessarily a poison to organisms allied to, or identical, with that producing nitric acid.—I am, &c.,

OTTO HEHNER.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 27, December 30, 1878.

Reply to M. Berthelot.—M. Pasteur.

Observations Concerning M. Pasteur's Communication.—M. Trécul.—A continuation of the controversy springing out of the posthumous work of Claude Bernard.

The Microphone in Subterranean Research.—M. d'Abbadie.—The speaker, in presenting to the Academy a work by M. Michel de Rossi "Il Microfono nella Meteorologia Endogena," remarked that the author had successfully applied the microphone to the study of underground movements, and that at his observatory at Rocca

di Papa, near Rome, he had been able to distinguish three kinds of sounds, and to trace their relation with the movements of his seismometers.

Harmotome and Stilbite.—A. Gaudin.—The author gives diagrams to show the atomic arrangement of these minerals.

Electro-chemical Action under Pressure.—A. Bouvet.—The author considers that he has established the two following laws:—That the decomposition of water by a current is independent of pressure. The quantity of electricity necessary to decompose a given weight of water is the same under whatever pressure the decomposition is effected.

Liquefaction of Gases by MM. Cailletet and Pictet.—A. Bouvet.—The writer points out that the principle made use of was indicated by him in a memoir addressed to the Academy on October 8, 1877.

Magnetic Rotation of the Plane of Polarisation of Light under the Influence of the Earth.—J. Joubert.—The author admits the reclamation of H. Becquerel concerning the experiment described in his memoir of December 23.

Use of the Telephone and Microphone in Scientific Researches.—M. Hughes.—These instruments may be advantageously employed, especially in researches concerning very feeble induction-currents resulting from the movement of a magnet before a helix.

A New Electric Lamp.—E. Ducretet.—The arrangement of the lamp cannot be described intelligibly without the accompanying figure. Its principal peculiarity is the use of a mercurial column into which the points are plunged.

Existence of an Oxide of Nickel, Ni_2O_3 .—H. Baubigny.—This oxide, unlike the corresponding iron compound, is not magnetic. It is formed on treating nickel chloride at 440° with moist oxygen, and appears as a grey metallic crystalline powder. It is slowly attacked by hot hydrochloric acid with liberation of chlorine, and at a strong heat it is reduced to protoxide, losing 6.6 per cent of its weight.

Nitrates found in Beets and in some other Roots.—J. A. Barral.—The highest percentage of nitrates calculated on the dry matter is found in the roots poorest in sugar.

Inactivity of the Chrome Compounds in Comparison with Vanadium in forming Aniline-black by means of Aniline Salts in Presence of Chlorates.—G. Witz.—The author, with reference to the memoir of M. Grawitz (*Comptes Rendus*, lxxxvii., p. 844), declares that the salts of chrome cannot be used in place of the salts of vanadium in their action upon aniline salts in presence of chlorates. The presence of chrome seems even slightly injurious.

Analysis of Crude Sugars and Saccharine Matters. Determination of Water and of the Totality of Salts with Mineral Bases and Organic Acids.—E. Laugier.—The author determines moisture by desiccation in hydrogen, or in coal-gas previously purified and dried. The total mineral bases are determined by incineration in a current of oxygen at temperatures below the melting-point of chlorides. In a second portion of exactly double the weight the organic acids are extracted with ether according to Schloësing's method and half the ethereal extract is poured to the ash obtained by the former experiment, thus re-constituting the previously existing salts. The mixture is again dried in the stove as in the determination of water and weighed. The second half of the ethereal extract is then neutralised with a standard alkaline liquid. From the result obtained is calculated the weight of the carbonic acid equivalent to the organic acids. By deducting from the weight of the salts that of the ash, less the weight of the carbonic acid expelled, we obtain the weight of the total organic acids, and of the

water which their salts retain at the temperature adopted for desiccation.

Innocuity of Borax Employed in the Preservation of Food.—E. de Cyon.—The author asserts that food thus prepared preserves all its nutritive value.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin,
No. 13, 1879.

Action of Dehydrating Agents upon Anhydrous Acids (Fifth Memoir).—S. Gabriel and A. Michael.—The authors examine the behaviour of phthalyl-propionic acid with sulphuric acid and with sodium amalgam; of ammonia with desoxy-benzoin-carbonic acid; and of sodium acetate with a mixture of anhydrous phthalic and isobutyric acids.

Determination of Vapour Densities.—A. W. Hofmann.—The author has been engaged with a course of experiments in order to ascertain the limits within which the determination of vapour densities in a barometric vacuum is usefully practicable. He describes a modified method for the expulsion of air, but purposes giving on a future occasion a detailed account of his methods and results.

The Formation of Methyl-aldehyd.—A. W. Hofmann.—The author passes a mixture of the vapour of methylic alcohol and of air through a platinum tube, not too narrow, containing a bundle of fine platinum wires. On the application of a gentle heat and condensing the vapours methylic aldehyd is obtained in quantity.

La Correspondance Scientifique.

December 10, 1878.

The Patent Office at Washington has refused to grant Mr. Edison a patent for his electric light, as his invention is merely a reproduction of that of Mr. Starr, of Cincinnati, whose patent dates from 1845. The English Patent Office is also said to have found Mr Edison's invention to have been anticipated by that of Chanzy, of Brussels, in 1852 laid by him before the Academy of Sciences February 25th 1858.

Syrup of orgeat is made of glucose made into an emulsion with oil and gum-tragacanth and flavoured with nitrobenzol.

The tin-paper used for covering chocolate and other essenculs has been found to contain 85 per cent of lead.

MISCELLANEOUS.

Society for the Encouragement of Arts, Manufactures, and Commerce, John Street, Adelphi, London, W.C.—One hundred and twenty-fifth session, 1878-79.—The following arrangements have been made for the forthcoming meetings of the Society:—Ordinary Meetings—Feb. 5, "The Best Methods for improving the Condition of the Blind," by Dr. T. R. Armitage. Feb. 26, "Indian Pottery at the Paris Exhibition," by George Birdwood, M.D., C.S.I. March 5, "The Social Necessity for Popular and Practical Teaching of Sanitary Science," by Joseph J. Pope, M.R.C.S., L.S.A. March 12, "The Compensation of Timekeepers," by Edward Rigg, M.A. March 19, "Economical Gardens for Londoners," by W. Mattieu Williams, F.R.A.S., F.C.S. March 26, "The Treatment of Iron to Prevent Corrosion" (a second communication), by Prof. Barff, M.A. In the Chemical Section—January 30, "Gas Illumination," by Dr. William Wallace, F.R.S.E. In the Indian Section—January 17, "Afghanistan," by C. E. D. Black, Col. H. Yule, C. B., R.E., will preside. January 21, "Quest and Early European Settlement of India," by George Birdwood, M.D., C.S.I. February 21, "The Trade of Central Asia," by Trelawney Saunders. March 7, "The Moral and Material Progress of India," by H. Phillips. In the African Section—January 21, "Retrospect and Prospect in Egypt," by B. Francis Cobb. February 4, "The Opening of the District to the North of

Lake Nyassa, with Notes of a Recent Expedition through that Country by H. B. Cotterell. March 18, "Some Remarks upon an Old Map of Africa contained in Janson's Atlas, published at Paris in 1612," communicated and exhibited by R. Ward. April 1, "The Contact of Civilisation and Barbarism in Africa, Past and Present," by Edward Hutchinson, Lay Secretary of the Church Missionary Society. **Cantor Lectures**—First Course, on "Mathematical Instruments," by W. Mattieu Williams. The remaining two lectures will be delivered on the following dates:—January 20 and January 27. The second course will be by Dr. W. H. Corfield, M.A., on "Household Sanitary Arrangements." It will consist of six lectures, to be given on the following dates:—February 17, 24, March 3, 10, 17, 24. The third course will be by W. H. Preece, on "Recent Advances in Telegraphy." It will consist of five lectures, to be given on the following dates:—April 21, 28, May 5, 12, 19. **Additional Lectures**—A Course of two lectures will be given by Dr. B. W. Richardson, M.A. L.L.D., F.R.S., on "Some Further Researches in Putrefactive Changes," in continuation and completion of his course of Cantor Lectures given last session. Any additions to or alterations in the above meetings will be duly announced.

MEETINGS FOR THE WEEK.

- MONDAY, 3rd.**—Medical, 8.30.
— London Institution, 5.
— Royal Institution, 8. General Monthly Meeting.
— Society of Arts, 8. "Some Further Researches in Putrefactive Changes," by Dr. B. W. Richardson, M.A., L.L.D., F.R.S.
TUESDAY, 4th.—Civil Engineers, 8.
— Royal Institution, 3. "Animal Development," Prof. Schäfer.
— Zoological, 8.30.
— Society of Arts, 8. "The Opening of the District to the North of Lake Nyassa, with Notes of a Recent Expedition through that Country," by H. B. Cotterell.
WEDNESDAY, 5th.—Society of Arts, 8. "The Best Method for Improving the Condition of the Blind," by Dr. T. R. Armitage.
— Geological, 8.
— Pharmaceutical, 8.
THURSDAY, 6th.—Royal, 8.30.
— Royal Institution, 3. "Electric Induction," J. H. Gordon.
— Chemical, 8. Discussion on Dr. Tidy's Paper on the Processes for Determining the Organic Purity of Potable Waters.
— Royal Society Club, 6.30.
— London Institution, 7.
FRIDAY, 7th.—Royal Institution, 9. "Bells," by Rev. H. R. Haweis.
— Geologists' Association, 8. (Anniversary.)
SATURDAY, 8th.—Royal Institution, 3. "Leasing," by Reginald W. Macan.
— Physical, 3. (Anniversary.)

THE MONTHLY JOURNAL OF SCIENCE AND ANNALS OF BIOLOGY, ASTRONOMY, GEOLOGY, INDUSTRIAL ARTS, MANUFACTURES, AND TECHNOLOGY.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1002.

ON THE TRANSMISSION OF POWER BY MEANS OF ELECTRICITY.

By Profs. ELIHU THOMSON and EDWIN J. HOUSTON.

THE statements recently made as to the size and cost of the cable that would be needed to convey the power of Niagara Falls to a distance of several hundred miles by electricity, have induced the authors to write the present paper, in the hope that it may throw light upon this interesting subject.

As an example of some of the statements alluded to, we may cite the following, viz.: That made by a certain electrician, who asserts that the thickness of the cable required to convey the current that could be produced by the power of Niagara, would require more copper than exists in the enormous deposits in the region of Lake Superior. Another statement estimates the cost of the cable at about 60 dols. per lineal foot.

As a matter of fact, however, the thickness of the cable required to convey such power is of no particular moment. Indeed, it is possible, should it be deemed desirable, to

FIG. 1.

convey the total power of Niagara, a distance of 500 miles or more, by a copper cable not exceeding one-half of an inch in thickness. This, however, is an extreme case, and the exigencies of practical working would not require such restrictions as to size.

The following considerations will elucidate this matter. Suppose two machines connected by a cable of, say, 1 mile in length. One of these machines, as, for example, A,

FIG. 2.

Fig. 1, is producing current by the expenditure of power; the other machine, B, used as an electrical motor, is producing power by the current transmitted to it from A by the cable C. The other terminals, x and y, are either put to earth or connected by a separate conductor.

Let us suppose that the electromotive force of the current which flows is unity. Since, by the revolution of B, a counter-electromotive force is produced to that of A, the electromotive force of the current that flows is manifestly the difference of the two. Let the resistance of A and B together be equal to unity, and that of the mile of

cable and connections between them the 0.01 of this unit. Then the current which flows will be—

$$C = \frac{E}{R} = \frac{1}{1.01}.$$

If now an additional machine, A', Fig. 2, and an additional motor, B', and an additional mile of cable, be introduced into the above circuit, the electromotive force will be doubled, and the resistances will be doubled, the current strength remaining the same as—

$$C = \frac{E}{R} = \frac{1+1}{1.01+1.01} = \frac{2}{2.02}.$$

Here it will be seen that the introduction of the two additional machines, A' B', has permitted the length of the cable c to be doubled, without increasing the strength of the current which flows, and yet allowing the expenditure of double the power at A A', and a double recovery at B B' of power, or, in other words, a double transmission of power without increase of current. Increase, now, the number of machines at A to say one thousand, and of those at B in like proportion, and the distance between them, or the length of the cable, one thousand, or in the case we have supposed, make it one thousand miles, its diameter remaining the same. Then, although the same current will flow, yet we have a thousand times the expenditure of power at one end of the cable, and a thousand-fold recovery at the other end, without increase of current. And the same would be true for any other proportion.

Since the electromotive force is increased in proportion to the increase of power transmission, the insulation of the cable and machines would require to be proportionally increased.

As an example it may be mentioned that a dynamo-electric machine used for the purpose of A in the figure, may have a resistance of say 40 ohms, and produce an electromotive force of say 400 volts. Such a machine might require from three to five horse-power when used in connection with a suitable motor B, for recovery of the power transmitted.

If the resistance of the motor B be, say, 60 ohms, and the cable transmitting the currents a distance of one mile be one ohm, then the current

$$C = \frac{400}{60+40+1} = \frac{400}{101}.$$

If, now, one thousand machines and one thousand motors, and a thousand miles of cable, each of the same relative resistances be used, the current

$$C = \frac{1000 \times 400}{1000 \times 101}.$$

which has manifestly the same value as before. If our supposition of the power used to drive one machine be correct, then from three to five thousand horse-power would be expended in driving the machines, and possibly about 50 per cent of this amount recovered. Then we have from 1500 to 2000 horse-power conveyed a distance of 1000 miles. What diameter of copper cable will be required for such transmission? Since this cable is supposed to have the resistance of one ohm to the mile, calculation would place the requisite thickness at about $\frac{1}{4}$ inch. If, however, the distance be only 500 miles, then

the resistance per mile may be doubled, or the section of the cable be decreased one-half, or its diameter will be less than the $\frac{1}{4}$ inch.

For the consumption of 1,000,000 horse-power a cable of about 3 inches in diameter would suffice under the same conditions. However, by producing a much higher electromotive force, the section of the cable could be proportionally reduced, until the theoretical estimates, which we have given in the first part of this paper, might be fulfilled. The enormous electromotive force required in the above calculation would, however, necessitate such perfect insulation of the cable, that the practical limits might soon be reached. The amount of power required to be conveyed in any one direction would, of course, be dependent upon the uses that could be found for it; and it is hardly conceivable that any one locality could advantageously use the enormous supposed power we have referred to.

Stripped of its theoretical considerations the important fact still remains, that with a cable of very limited size, an enormous quantity of power may be transferred to considerable distances. The burning of coal in the mines, and the conveyance of the power generated by the flow of rivers, may therefore be regarded as practicable, always, however, remembering that a loss of about 50 per cent will be almost unavoidable.

It may be mentioned that Dr. C. W. Siemens and Sir William Thomson have recently made statements that are in general accordance with the views here expressed.

ON THE EFFECT OF HEAT ON THE DI-IODIDE OF MERCURY, HgI_2 .*

By G. F. RODWELL, Science Master, and H. M. ELDER, a Pupil in Marlborough College.

IN continuation of the experiments on the effects of heat on the chloride, bromide, and iodide of silver, which one of us has previously had the honour of communicating to the Society,† it was thought to be advisable to search in some of the other metallic iodides for molecular anomalies similar to those presented by the iodide of silver. Among these no substance appeared more likely to possess such anomalies than the di-iodide of mercury. This substance, as is well known, is dimorphous. In the amorphous condition it presents the appearance of a brilliant scarlet powder, which, if heated, fuses at 200°C ., and volatilises just above the fusing point to a vapour more than twice as dense as that of mercury. The vapour condenses to rhombic prismatic crystals, which frequently become scarlet while cooling, but which, if they still remain yellow when cold, instantly become scarlet if rubbed or otherwise mechanically agitated. According to Warrington, this change is due to the transformation of the rhombic prisms into acute square-based octahedrons with truncated summits. If the yellow prismatic crystals are placed under the microscope, and are then touched, the change to the red variety may be observed to go on through the mass of contiguous crystals, accompanied by a slight movement, but the external form of the crystals remains unchanged, consequently pseudomorphous crystals are produced; and the larger rhombic prisms have been resolved into a mass of minute octahedrons. Frankenheim asserts that by the application of a very gentle heat both the red and the yellow crystals may be sublimed together, and he believes that the vapour of the yellow crystal passes off at a lower temperature than that of the red. Warrington found that the precipitate produced by iodide of potassium in chloride of mercury appeared under the microscope to be composed of rhombic laminæ, which gradually altered their form by the

truncation of the edges until they disappeared, while square-based octahedrons were produced in their place.

The iodide is clearly capable of existing in two crystalline forms belonging to different systems, and of passing from one form to the other, either by diminution of temperature or by simple mechanical means. Such a substance would seem to be likely to possess peculiarities in its modes of expansion under the influence of heat. In order to test this the iodide was submitted to the same experimental treatment as that employed in the case of the iodide of silver, and previously described in detail.

Homogeneous rods of the iodide of mercury were heated in paraffine in the expansion apparatus described and figured in the previous paper, and the extent of expansion due to a given range of temperature was noted. The apparatus was standardised by means of a rod of fine homogeneous silver. The same micrometer, reading to $\frac{1}{1000}$ th of an inch, was employed, and the mode of conducting the experiments was precisely the same as in the case of the iodide of silver. Two slight changes were made in the apparatus, however:—the one consisted in the substitution of a massive stone base for the wooden one hitherto used; and the other the replacement of the glass rods moving in stuffing boxes by curved equal-armed levers moving over the rim of the trough, by which means the leakage of hot paraffine at the stuffing boxes was prevented.

Bars of the iodide of mercury were cast in clean glass tubes, and here at the outset the experimental difficulties commenced. For not only was it difficult to obtain a homogeneous rod, on account of the volatilisation of the iodide at a temperature slightly exceeding its melting point, but the rod when cold was found to be so brittle that it usually broke in the attempt to remove the glass envelope from the outside. Eventually good rods were procured by slowly melting the iodide in thin glass tubes and annealing in hot paraffine. When the whole was cold the glass was cut on the outside, and carefully broken off the ends of the rod, which were sawed plane by a fine steel saw, and then furnished with metal caps, and the rod was placed between the levers of the expansion apparatus. After heating the bar once or twice in paraffine to a temperature approaching its melting-point longitudinal rifts appeared in the glass envelope, which was then easily removed, leaving a clean homogeneous rod of the iodide.

On heating a mass of the crimson amorphous iodide, it turns yellow at 126°C ., and just before the melting-point is attained the yellow changes to a deep red-brown. The liquid resulting from the fusion has the appearance of liquid iodide of silver, that is to say, it has the exact colour of bromine. The liquid when cooled solidifies to a red-brown solid, which speedily becomes yellow, and at 126°C . it changes to the crimson octahedral variety. Distinct cracking sounds, due to inter-molecular movements, were heard during the continuance of the change. Heat is absorbed when the red iodide changes to yellow, and is given out when the yellow iodide changes to the red.

A bar of the iodide was placed in the expansion apparatus, melted paraffine was forced upon it, and when the index had become quite steady, a gentle heat was applied to the paraffine. The index showed a regular and slow expansion until a temperature of 126°C . was reached, when the bar began to change from the octahedral to the prismatic condition, and without further rise of temperature rapid expansion took place. The temperature was kept constant until the change was complete, and was then slowly raised. A regular expansion now took place under a higher coefficient than before the molecular change, and this continued until the melting-point was attained. The results were concordant.

The expansion in passing from the solid to the liquid condition was determined by weighing mercury in a tube, and afterwards filling it to the same height with fused iodide. The specific gravity of each substance being

* Paper read at the Royal Society.

† *Proc. Royal Society*, vol. xxv., p. 280.

known, and the weight of equal volumes, the expansion could obviously be readily determined.

The coefficient of cubical expansion for 1° C. from 0° C. to the point of change—126° C.—was found to be:—

$$0.0000344706.$$

At 126° C., during the change from the red octahedral to the yellow prismatic condition, the body increased in bulk to the extent of:—

$$0.00720407.$$

The coefficient of cubical expansion for 1° C. from 126° C., after the change, λ , to the melting-point 200° C., was—

$$0.0001002953.$$

Thus, if we suppose a molten mass of the iodide of mercury to be cooling down from 200° C. to 0° C., the following would be the volumes under the conditions, indicated:—

Vol. at 200° C. of the liquid mass	 = 1	.1191147
" " solid mass	 = 1	.0190453
" 126° C. (yellow prismatic condition)	= 1	.0115378
" " (red octahedral condition)	= 1	.0043337
" 0° C.	 = 1	.0000000

According to Schiff the specific gravity of the octahedral iodide is 5.91; while Karsten makes it 6.2009, and Boullay 6.320.

Two distinct specimens with which we worked gave respectively—

- (1). 6.3004
- (2). 6.2941

The specific gravity of the fused iodide was found by the method before described to be

$$5.2865.$$

Thus the specific gravities corresponding to the five marked conditions shown in the curve table are as follows:—

Sp. gr. at 0° C.	 = 6	.297
" 126° C. (octahedral condition)	.. = 6	.276
" " (prismatic condition)	.. = 6	.225
" 200° C. solid	 = 6	.179
" " liquid	 = 5	.286

THE CULTIVATION OF CHEMISTRY.*

By F. W. CLARKE, S.B.,
Professor of Chemistry in the University of Cincinnati.

(Concluded from p. 51).

ALTHOUGH the foregoing statements relate specifically to the first of the three great problems, similar principles apply to the second. If we are to determine what general laws connect the properties of compounds with those of the elements contained in them, we must first secure a large mass of well-established data to work from. For a very large number of substances, such constants as density, crystalline form, melting and boiling point, thermal conductivity, specific and latent heat, co-efficient of expansion, index of refraction, electrical resistance, and so on, ought to be rigorously ascertained. With such accurate data, we may hope to reach the desired laws; without them we can see but a little way. Moreover, every constant should be determined in a much more thorough manner than any have been determined hitherto. Every measurement should be repeated many times, and under all attainable conditions; otherwise the work would be manifestly incomplete.

Fragmentary researches of this kind have already been carried out in great number; but how? In some directions

I have tried to collect the evidence, in order that we might know what data were really available, and where the worst gaps lay. The discrepancies which sometimes come to light are amazing. Take a large number of specific gravity determinations for any given compound, and see how discordant they are. The values will range through wide limits, so that it is often impossible to say which one out of several is the best. These variations may be due partly to bad work, and partly to unrecognised differences in chemical constitution. Some of them are so peculiar that they can hardly be explained, except upon the hypothesis that they spring from some undiscovered allotropy or isomerism. The metallic iodides furnish some good illustrations of this idea. The well-known properties of mercuric iodide, Rodwell's experiments upon silver iodide, and Cooke's researches into antimony iodide are sufficiently suggestive. When, therefore, we meet with discordant specific gravity determinations among other iodides, we may reasonably suppose that one experimenter has dealt with one allotrope, and another with another, both unconscious of any existing differences. But however this may be, the discordance of so many data, not only among specific gravity measurements, but in all other series of determinations, serves to show how little we really know, how much work remains to be done freshly, and how much ought to be done over again. Of all the figures upon which we now rely for the solution of these grander problems, at least three-fourths should be scrupulously re-determined; and even after that had been done our material would still be woefully insufficient. The kind of work we need may be well illustrated by the classical labours of Stas upon the atomic weights, and the immortal researches of Regnault into the physical properties of vapours. Such work as this will give imperishable foundations for exact science, strong enough and broad enough to sustain the most stately edifice which the human intellect can rear.

To my mind, the investigation of this sort most immediately needed is the accurate determination of all the physical constants for all the so-called elements. This would supply evidence directly related to all three of the great problems. We might thus learn something about the nature of the elements themselves, and how far the transformations of energy due to chemical action depended upon their individual characters; we should also be put in some position to predict the properties of compounds. In many important lines of research, science would then replace speculation, and the imagination could still find ample fields in which to exert its powers. As yet such work as this has not been done for even one of the sixty-five or sixty-six elements known. Take iron, for example,—the most important of the metals, one which has been the subject of numberless practical researches,—and we as yet know it in these more purely scientific relations barely on the surface. Not a single series of physical constants has yet been thoroughly determined with regard to it, notwithstanding the light that such investigations might shed upon important industrial problems. We know a little here and a little there; a bit about its thermal properties and another bit about its electrical properties, but nothing systematically and well. As for gold, silver, copper, and mercury, rather more is known; but even with these elements not a tenth of what ought to be done has really been accomplished.

The reason for such incompleteness in chemistry is sufficiently evident. Indeed I have already hinted at it. The labour of investigation hitherto has fallen chiefly upon the shoulders of volunteers, who have worked in great measure independently of each other, every man following his own particular bent. Part of the work has been done by teachers, in their odd moments of freedom from the drudgery of instruction; other portions were carried out by inventors, or by manufacturers with reference to special industrial questions. There has been little co-operation, and no organisation of efforts. The one class of investigators has sought for the glory which brill-

* Address before the Permanent Sub-section of Chemistry of the American Association for the Advancement of Science, at the St. Louis Meeting, August, 1878.

liant discoveries bring; the other has laboured to secure pecuniary rewards. Thus has our pure science grown unsystematically, and our applied science has been imperfectly applied. The two depend on each other; and the more complete pure science can be made, the simpler and more beneficent will its applications become.

What chemistry needs, then, is combined effort upon some general plan. There must be a body of trained workers under an efficient head, who shall mark out some of the lines for investigation to follow. Such a co-operation can hardly be brought about under existing circumstances and with present facilities, since as a matter of course every scientific man prefers to work independently, and to shape his researches for himself. Something may be done, perhaps, by those college professors who are fortunate enough to have a considerable number of advanced students to assist them; but work carried forward under such conditions can scarcely amount to more than a clearing of the ground. Still such pioneer labour is not to be despised. It marks out many useful pathways for us, and shows where the chief difficulties are to be encountered. The one great method, however, by which the desired ends may be attained is to be found in the establishment of endowed laboratories devoted to pure research. With regard to laboratories of this kind much has been written, both for and against. From two distinct points of view has the subject been treated. One set of writers has opposed the idea of endowing research, upon what appear to me to be wholly fallacious grounds. They have urged that the payment of salaries to scientific men, either as a reward for past services or as a means of encouraging future work, would probably result in the foundation of sinecures in which pretentious idlers might find an excuse for doing nothing. A man could easily pretend to make investigations, and in reality only fritter away his time in a sort of elegant leisure. No endowment would render brilliant discoveries certain, so that fruitlessness might find ready apologies. This is a somewhat extreme statement of the case, though not a wholly unjust one. Such forebodings as these might be realised, although it does not to me seem probable that the men who now labour so earnestly and assiduously for the love of knowledge would accomplish any less because of greater encouragement. Still an endowment which afforded large salaries for no regular, specific duties, might in some cases work mischief. The true man of science would hardly advise even a possible wasting of means.

The idea of an endowed laboratory for research is of a very different kind. It proposes an institution in which salaries shall be paid for work of a definite, prescribed character. Men would not be employed in it to make showy discoveries, although these might be rendered incidentally possible. The laboratory would, in short, be a place wherein the fundamental data of chemistry and physics should be accurately established, without more than casual reference to particular industrial questions or to theories. In it a body of trained specialists would co-operate upon such researches as I have suggested; they would fix some of the foundation stones of science; they would combine their strength upon those tasks which are too large and too arduous for individuals to undertake. Just as an astronomer makes an exact map of a given zone in the heavens, observing the position of each star over and over again; so the workers in this laboratory would undertake repeatedly those delicate measurements which physical science so much needs. The physical properties of substances could be exactly determined; methods of measurement could be tested and improved; apparatus too expensive for individuals to own might be constructed and employed; the quantitative relations of the several forces could be accurately ascertained. One great problem at a time might be taken up, and the energy of the whole body of workers concentrated upon it. Under ordinary existing circumstances a scientific man teaches several hours a day, and after that he labours at research. Here he would have a different routine from

that of teaching, and probably as much leisure for himself and his own ideas as before. Indeed, to carry out the latter his opportunities would be vastly improved.

Who can doubt that such a laboratory would benefit science? To have important data systematically determined, with every conceivable precaution and the best appliances, would certainly be worth while. Every industry involving applications of physics or chemistry would be aided. The special problems of the ironmaster might not be touched, and yet evidence would be discovered which should enable him to solve them much more easily and certainly than before. Precision would be gained everywhere; in facts, in methods, and in appliances; theories would rest on more solid foundations; the intellect would find new food for thought. The work done might seem at first sight to be of the hardest, driest, and most practical character; and yet there would be within it more than utility. We cannot deepen our knowledge of the real without at the same time broadening our insight into the ideal. The more we know, the vaster the unknown seems to us. The better we know, the more truly do we recognise the imperfections of our knowledge. We climb each mountain only to see a bluer, higher, grander summit far beyond.

Can this conception of a laboratory for pure research be realised? I believe it can. Physics and chemistry have created millions upon millions of wealth; they have helped to bring distant countries nearer together; they have benefited every human being within the limits of civilisation. In every country of the civilised world there are many rich men who owe their wealth to the applications of these sciences. In our own country especially, we find such men ready and often anxious to give. Every day we hear of large bequests for public purposes; of gifts to colleges, libraries, observatories, and museums; to hospitals, asylums, and churches; to the poor and to the heathen. Surely some of the wealth which our science has rendered possible ought to come back a little more directly for her benefit. There must be men who would give liberally to her purposes if they only knew of her needs. Can we not do something towards making our wants known? Are we not able to present a strong case in our own favour? Might we not by some combined effort at least make a beginning, and secure a fund, which should serve as a fulcrum for our future exertions? Let a nucleus once be established near some large university, or under the control of such an institution as the Smithsonian, and it cannot fail to grow. If the first organised laboratory, for such work as I propose, could be founded in this country, it would soon be recognised as a national glory and a benefactor of the whole human race. I throw out these suggestions merely as suggestions, with the hope that some means may speedily be found which shall lead us to the much desired end.

In Europe the needs of science are often liberally provided for by Government. The scientific institutions of Germany, for example, owe their existence and support chiefly to funds drawn from the public treasury. This policy I believe to be wise and proper, although it might not be judicious to urge it strongly here. With us, the proposal to establish a purely scientific institution, upon moneys raised by general taxation, would undoubtedly be seriously opposed. The public importance of the measure would be obscured by a clamour about economy, and upon the wickedness of expending the means of the many for the benefit of the scientific few. Much of this opposition would be foolish, although at the same time effective. Still, granting that it might be unwise to ask the National Government to establish a laboratory for research, there is another kind of laboratory which it might build, equip, and organise, with unquestionable propriety.

All the time the General Government finds it necessary to employ chemists for special expert work. For the Bureau of Engraving and Printing investigations are made with reference to the inks and paper used in the manufacture of notes and bonds. Questions are con-

tinually arising in connection with the custom houses, which can only be settled by the testimony of a reliable chemist. Frequently the Examiners of Patents would be much aided in their decisions if they had laboratory facilities at their command. The War and Navy departments are continually needing work done, it may be in the examination of supplies, in testing metals, or in experiments upon explosives. For the Lighthouse Board there are oils to be tested, and for the Geological Surveys there are rocks and minerals to be analysed. As for the Agricultural Department, it already has a small laboratory, and there is another connected with the Army Medical Museum. These examples do not by any means complete the list; they only serve to show how great an amount of scientific labour the National Government is obliged annually to employ. The work is now done in a scattered way, often with imperfect appliances, and much less thoroughly than is desirable. The question I now raise is this: Would it not be eminently proper for the Government to establish a first-class chemical and physical laboratory, in which all of its work in these departments should be done by an adequate body of scientific men, provided with the best materials and apparatus? Would not this be a measure of true public economy? Could not more and better work be done for a given sum of money than is done now? To me it seems that the plan is decidedly practical, and that Congress might by judicious pressure be induced to carry it out. Of course the measure is open to the usual political objections. It might enable inefficient men to get responsible positions through political influence; and there would be a possible danger that corruption should secure another foothold where it is already too firmly lodged. This objection I do not believe to be sound. At present experts may be employed through political favour, while the country at large knows nothing of what is going on. In a national laboratory the appointments would be conspicuous, and mismanagement would at once be recognised. There is an argument from analogy which may be even stronger than this. Whatever weakness our public officers in general may have exhibited, our scientific service has always been remarkably able and strong. If the proposed laboratory could be made as efficient as the Naval Observatory, the Coast Survey, or the Army Medical Museum; if it could secure as thorough men as these have secured, the objections just urged would disappear. The nation must get the work done somehow, and would it not be best done in the manner I propose?

Such a laboratory as this, organised at first for the merely practical work of the Government, might in course of time widen its scope a little. The National Observatory, established originally for the purposes of the Navy Department, has been able to do much for science beyond its purely routine labours. The expenditure of public money for eclipse and transit expeditions, in furnishing the means for work like that of Newcomb and Hall, has been for the interests of abstract science; but I doubt whether any intelligent citizen has ever begrudged a dollar of it. The nation has been ennobled by such researches, even though no material benefits should ever spring from them. So with a national laboratory. At first its work would be only a technical routine; but sooner or later this would necessarily develop into something more. The Government investigations could not be carried on for ever by imperfect methods; and accordingly better methods would have to be devised. Whatever researches tended towards improving the work done for the nation would, of course, be properly carried out in a national laboratory. Thus an institution, established for practical purposes at public expense, could at the same time benefit the public service, and advance the interests of science. The cost would be justified over and over again in a purely material way, so that the question of the usefulness of the laboratory could never be seriously raised.

- As we are gathered together for the Advancement of

Science, I may be permitted to broach one more subject which I believe to be of some importance. Year after year the researches of American chemists are steadily increasing in number, extent, and value. Work like that of Gibbs, Cooke, Smith, Mallet, Remsen, Jackson, and a dozen others who might be named, is certainly work of which we may reasonably feel proud. But how is all this material published? A little of it in the *American Journal of Science and Arts*; a part in certain foreign periodicals; another portion in several local transactions, as for example the *Proceedings* of the American Academy. In short, the work is widely scattered, and some of it is effectually buried beyond the reach of a majority of our fellow chemists. We need, I believe, in this country, a good chemical journal which shall fairly represent the work that America is doing for chemistry. A journal in which every chemical research published in the United States should find a place, either in full or in abstract, would certainly stimulate investigation among us, and send all over the world a truer estimate of our scientific standing. We might have for our organ a chemical periodical equal to any in the world, and I sincerely hope that we may not have to wait long for its establishment. Where or by whom it should be edited and published is a question I will not attempt to raise; suffice it to say that it ought to be controlled by no local clique, and managed in no Pharisaical spirit. It should be broad enough not to fear novelty, and courageous enough to reject trash; two qualifications more easily stated than found. I throw out these suggestions, hoping that they may take root somewhere, and that without much delay. Even though we ourselves may lack the power to carry them out, our recognition of their importance may lead to action elsewhere. If we in our gatherings can point out good pathways, others with richer means may be induced to follow them. Our united counsels and combined efforts may achieve results where, working separately, we should fail.

THE SEVEN FUNDAMENTAL TYPES OF ORGANIC CHEMISTRY,

AS VIEWED AND INTERPRETED FROM THE STANDPOINT OF THE "TYPO-NUCLEUS" THEORY.

By OTTO RICHTER, Ph.D.

(Concluded from p. 48.)

In passing on to consider the second stage of the process, we may suppose that, by a species of lateral movement on the part of the newly formed subjunct nucleus away from the outer or inner conjunct chamber towards the outer or inner subjunct chamber, that molecule, while it remains still firmly attached to the principal nucleus by means of its appropriate number of thermal bonds, will at length arrive at the particular point whence it may be brought to take up a fixed and well-defined position within the corresponding subjunct chamber, a position which it will undoubtedly continue to maintain after the whole system has returned from the nascent state of unstable equilibrium into the quiescent state of stable equilibrium. It is scarcely necessary to add that at the close of this second stage of the process no substitutional action has as yet taken place, the affected molecule having simply undergone that particular preparatory treatment which befits it for the exercise of its newly acquired chemical duties and functions. Finally, as regards the third and last stage of the process which, in the majority of cases, involves the presence and co-operation of two contending molecules, its chief characteristic feature consists in the successive interchange of one or more thermal bonds with simultaneous transfer of their respective subjuncts from one principal nucleus to the other.²

Reserving the fuller discussion of this important subject for a future communication, I shall here content myself with a brief enunciation of the general law which I hold to preside over this particular order of chemical phenomena. But before doing so it will be necessary for me to pass a few observations on the proper meaning and use of the technical terms "Multivalence" and "Quantivalence," terms which, the reader will not fail to remember, have now and then formed the subject of very animated but far from satisfactory controversies in our leading journals and debating societies.

In pondering this question from the novel and more elevated standpoint of my "Typo-nucleus" theory, I was not slow in perceiving that a fatal error had been committed by either side of combatants in not sufficiently discriminating between the absolute substitutional power and capacity of a principal nucleus pure and simple and the relative substitutional power and capacity of that same nucleus when associated with a variable number and quality of outer or inner conjunct molecules.

From an extensive series of researches in this direction I have arrived at the interesting and all-important conclusion that in the former case the said power and capacity is always measured and expressed by one single thermal bond only, because it forms the only connecting link between the two semi-nuclei into which the original molecule has been made to resolve itself, while in the latter case the said power and capacity is always measured and expressed by the variable number and quality of those outer or inner conjunct molecules which have passed from the original state of conjuncts into the typically altered state of subconjuncts. Now, in my mode of viewing the term, "Multivalence" is correctly employed whenever we wish to indicate the aggregate number of chemically similar or dissimilar conjunct molecules that have entered into direct chemical union with a given principal nucleus, while the term "Quantivalence" is correctly employed whenever we wish to indicate the number of subconjunct molecules into which the whole, or a certain part only, of associated conjunct molecules have been successively converted, it being distinctly understood that such conversion is invariably accompanied by the simultaneous formation of a corresponding number of as many thermal bonds as are lawfully required to serve as connecting links between the principal nucleus and its evolved subconjuncts.

The preceding statements and explanations will, I trust, enable the reader to grasp the full scientific bearing and significance of the remarkable law above referred to, and which may be briefly enunciated as follows:—The substitutional power and capacity of a given principal nucleus, after it has entered into direct chemical union with a given number of outer or inner conjunct molecules is a variable and fluctuating quantity, which is measured and expressed *pro tem.* by the collective number of thermal bonds emanating from that particular set of outer or inner conjunct molecules which have been made to pass from the original state of conjuncts into the typically altered state of subconjuncts."

It deserves to be borne in mind that the said power and capacity is entirely independent of the chemical nature of the element out of which the principal nucleus has been moulded, for that element is found to contribute not one single unit to the sum total of the thermal bonds collectively attached thereto. We are thus driven to the unexpected but inevitable conclusion that the substitutional power and capacity with which our modern speculators are in the habit of crediting the principal nucleus does not reside therein at all, but may be said to exist in a kind of latent state within the outer or inner conjunct molecules, until the conversion of the latter into the corresponding subconjuncts causes that power and capacity to become revealed under the form of interchangeable thermal bonds which, as a variable and fluctuating quantity, are made to range between the more or less circumscribed limits of a well-defined maximum and minimum.

It is now time for me to dismiss this singularly attrac-

tive and fascinating subject, in order to examine into the last remaining set of fundamental types which I have represented as standing under the immediate control of the principle of polarity or chemical principle. This principle rests upon the hypothesis that in their nascent or chemically active state of existence every species of molecules, from the simplest to the most complex, is capable of being transiently thrown into a state of electrochemical polarity. This new kind of agency is supposed to attain its maximum of force in the direction of a straight line intersecting the molecule at right angles to its operative axis, and coinciding with the polar axis of that molecule; while in a plane at right angles to that axis, which coincides therefore with the equatorial plane of that molecule, the said agency is supposed to attain its minimum. This hypothesis, strange and mysterious though it may appear at first sight, leads at once to the consideration of two possible alternatives. In the first alternative, any two conflicting molecules may be represented as confronting each other in such a way that the polar axis of the one becomes opposed to the polar axis of the other; while in the second alternative they may be represented as confronting each other in such a way that the polar axis of the one becomes opposed to the equatorial plane of the other.

Applying this hypothesis to the direct chemical union of two or more principal nuclei with each other, I have arrived at the conclusion that all the members of the outer adjunct type which embrace the true polyatomic alcohols and their numerous basic and acid derivatives owe their origin and formation to the first of these alternatives, and, again, that all the members of the inner adjunct type which embrace the pseudo-polyatomic alcohols and their numerous basic and acid derivatives owe their origin and formation to the second of these alternatives. It deserves special notice also that the typical differences arising from the circumstance that the chief component groups of the former class of molecules are co-ordinately, because axially and axially, united, while those of the latter class of molecules are subordinately, because axially and equatorially, united, are of such a nature as materially to interfere with the general law of molecular collocation and arrangement. From a host of well-established experimental facts and observations I have it in my power to prove that, while the general law continues to exercise an absolute control over all the members of the outer adjunct type, it is no longer applicable to the members of the inner adjunct type, where its frequent infringement is apt to give rise to a great number and variety of isomeric compounds, the formation of which seems chiefly to depend upon the precise order in which certain organic and inorganic bases or acids are made to unite with that class of molecules.

Having now submitted to the reader a brief and tolerably complete general outline of the seven fundamental types of chemistry as collectively exhibited and placed side by side in our model molecule, I may yet be allowed, in drawing to a close, to give vent to a few appropriate remarks and sentiments.

It is my humble opinion—an opinion that is probably shared by the majority of unbiassed and more calmly reflecting chemists—that, in the course of its marvellously rapid progress and development our science has at length arrived at that critical turning-point where its votaries are compelled to answer to themselves the question—"Is it meet and desirable in the face of such an overwhelming mass of ever-accumulating facts that we should still go on contenting ourselves with the adulterated and unpalatable compost of antiquated notions and untenable dogmas, hallowed though they may be by the honoured memories of so many deserving and illustrious experimentalists, and may it not be that our boasted knowledge and pretended insight into nature's secrets is merely a gross delusion and a snare, the natural result, in fact, of grave speculative errors and prejudices, which must inevitably melt away under the genial rays of a more profound and enlightened

system of chemical philosophy?" Already, if we may judge from certain highly interesting and invaluable contributions to spectroscopy with which Mr. Norman Lockyer and others have recently regaled the chemical profession, a new and unexpected light has suddenly been brought to bear upon the all-important question whether the chemical elements ought still to be regarded as simple bodies in the ordinary sense of the word, or whether these elements ought not rather to be regarded as more or less complex bodies that, under the dissociating influence of temperature, may, like other truly compound substances, be brought to resolve themselves into molecules of lower atomic weight, and presumably also of different chemical and physical properties, from their parent molecules. It is contended—and I think rightly so—that these wonderful spectroscopic discoveries are totally inexplicable on the prevailing biatomic hypothesis. What other hypothesis then, I would ask the reader in all humility, remains for our final adoption but that same polyatomic hypothesis which forms the theoretical basis of that very system of chemical philosophy I have been the first in expounding and elaborating—a system, moreover, which, with respect to the splitting up or condensation of chemically simple or compound molecules, presents no difficulties whatsoever, while it possesses in these two opposite tendencies a ready and fertile source for the complete elucidation of many hitherto obscure and unintelligible chemical phenomena. With regard to the fundamental axiom which underlies my whole chemical system, namely, that not only every species of chemically elementary molecules, but likewise every variety of chemically compound molecules, as embraced under the generic term "Model Molecule," are made to exhibit relatively to the three conjugate axes of space the most perfect symmetry of form and atomic arrangement, I have yet to observe that our model molecule with its seven-chamber system, in order to satisfy the aforesaid fundamental law, requires to be doubled; in other words, that such molecules require to be united into one by joining them together with their inner adjunct chambers. It will at once be seen that, under this new aspect, the symmetry of the whole system is rendered perfect; and I may now state, in addition, that this re-duplication of our model molecule will not oblige me to alter my customary mode of notation, if it is taken for granted that any molecular changes in the right moiety of our model molecule are invariably and simultaneously accompanied by similar molecular changes in the left moiety.

In now taking final leave of my subject, I may yet be permitted to express an anxious hope that the arduous but imperatively necessary task of a thorough revision and reconstruction of the groundwork of theoretical chemistry—a task initiated by me a number of years ago, and evidently desired and prayed for by that small but rapidly increasing band of chemical practitioners whose reasoning powers have not as yet been crippled and paralysed under the withering influence of a perverse and unyielding dogmatism—may soon engage the earnest and undivided attention of our leading men of science, and induce them to countenance and second my isolated and hitherto scarcely appreciated efforts by honouring with a fair, impartial, and candid criticism those novel and original views and principles I have ventured to advance and to publish in this and preceding communications.

A NEW FAST GREEN AND MALACHITE GREEN.

By Messrs. BINDSCHIEDLER and BUSCH.

Up to the present the so-called methyl-green has been obtained from dimethyl-aniline by converting the latter into violet by oxidation, and then the violet again by methylation into green.

It has long been the endeavour of the manufacturers of aniline colours to get the green direct from dimethyl-

aniline without going through the violet; and taking as starting-point the theoretical and meritorious studies of Prof. A. Baeyer, Otto Fischer, in Munich, and Oscar Doebner, in Berlin, it has been found possible to produce green direct from dimethyl-aniline, and even at a very low price.

These direct greens are brought into the market under the names of New Fast Green, Malachite Green, &c., and possess about the same chemical qualities, but the mode of manufacture and the attention paid to the same, cause more or less a difference in brilliancy of shade and yielding. It is, however, very easy to distinguish direct greens from methyl-greens through the simple fact that wool, silk, or cotton, when dyed with direct greens, can stand a very high degree of heat without the green colour turning into violet; whilst stuff dyed with methyl-greens turns violet when brought into contact with an iron exceeding 120° of heat.

The aforesaid theoretical mode of Otto Fischer, in Munich, was published in the reports of the Berlin Chemical Society on August 11, 1877, under the title of "Condensations Produkte Tertiärer Aromatischer Basen." Otto Fischer describes therein a new base, which he obtains by the reaction of dimethyl-aniline, chloride of zinc, and hydride of benzyl, and further states that oxidising the salts derived from his method led to the production of a beautiful bluish green colour.

The exceedingly high price of the hydride of benzyl has hitherto prevented the practical application of Fischer's most interesting discovery. Now, however, this material is produced at a price which renders its practical use quite possible.

The process of manufacturing malachite-green is based upon the theoretical studies of Oscar Doebner, published in the reports of the Berlin Chemical Society, May 27, 1878.

Doebner proves in his report that green can be obtained direct from dimethyl-aniline, chloride of zinc, and trichloride of benzol.

Besides the before-mentioned system of producing direct greens through the medium of hydride of benzyl, there are other methods by which the same can be obtained: for instance, the product of the reaction of dimethyl-aniline, chloride of zinc, and dichloride of benzoyl, submitted to oxidation, gives a very beautiful and cheap green.

From the preceding statement it is obvious that different methods of manufacturing direct green exist.

THE GRAHAM LECTURE.

THE Philosophical Society of Glasgow have determined to institute a triennial lecture in memory of the late Prof. Graham, Master of the Mint, who was for thirty or forty years a member of that Society. He communicated some of his earliest papers to it before publication of its Transactions was undertaken. The Council have also caused a portrait medal of the value of £10 to be struck, and this they propose to award every third year for the best original investigation, either in chemical physics or in pure or applied chemistry, which may be communicated to the Society or to its Chemical Section in the interval of the awards. The choice as first Graham Lecturer appropriately fell on Mr. W. Chandler Roberts, F.R.S., who had so long been associated with Graham's work, and who was enabled to employ for the purposes of demonstration much of the apparatus that had been used by his distinguished master. A very large audience assembled on the 22nd of January in the Hall of Glasgow University, where Graham graduated in 1824, and the chair was at first occupied by Mr. JAMES MACTEAR, President of the Chemical Section, who pointed out that they were doubly fortunate in having secured the services of Mr. Roberts, and in the fact that Mr. James Young, F.R.S., of Kelly,

the life-long friend of Graham, had consented to preside on the occasion; he therefore vacated the chair in favour of Mr. YOUNG, who briefly introduced the Lecturer.

Mr. ROBERTS briefly traced the influence of Black and Thomson in turning the attention of Graham to the study of molecular physics, to which he patiently devoted his life. In connection with the law of diffusion of gases, the Lecturer claimed that Priestley made in 1799 an observation on the escape of hydrogen from a cracked jar. The subsequent and independent discovery of this phenomenon by Doeberiner in 1823 has hitherto been considered the starting-point of the experimental study of gaseous diffusion, to which it undoubtedly attracted Graham's attention. After a brief notice of the influence of Eastern and Greek thought on the study of molecular movement, allusion was made to Sir Christopher Wren's model representing the effects of all sorts of impulses that result from the impact of hard globulous bodies, which, according to Dr. Sprat (historian of the Royal Society), he proposed as the principles of all demonstrations in natural philosophy, it being considered "that generation, corruption, and all the vicissitudes of nature are nothing else but the effects arising from the meeting of little bodies, of different figures, magnitudes, and velocities." Herapath's revival of Bernoulli's view as to the movement of gaseous particles was considered, and Mr. Roberts then described in detail the experiments that enabled Graham to establish the law of the diffusion of gases, and he illustrated experimentally the passage of gases through porous bodies, such as unglazed earthenware and artificial graphite, as well as through a layer of the hard translucent variety of opal known as hydropbane. The mode in which Graham studied the diffusion of the momentum of gases, by observations on viscosity as indicated by rates of flow through capillary tubes, was then described. It was pointed out that his law of diffusion forms the basis of the science of molecular mechanics, and his measurements of the rates of diffusion prove to be the measure of molecular velocities which have been so profoundly investigated mathematically by Clerk-Maxwell, Clausius, and Boltzmann, and experimentally by Loschmidt in developing the dynamical theory of gases. Mr. Roberts then considered the passage of gases through colloid or jelly-like bodies which have no sensible pores, dwelling more especially on the separation of oxygen from air by the transmission of air through a thin film of india-rubber, a circumstance of special interest from a physiological point of view. The liquefaction of gases formed the subject of one of Graham's earliest papers in 1826, and it occupied his attention at intervals during his life. He held the view that hydrogen when absorbed by palladium is reduced to the metallic form, a supposition which has received strong confirmation from the success that has attended M. Raoul Pictet's efforts to solidify this gas; and that distinguished physicist stated in a letter to Mr. Roberts that it is probable Graham's indication of the density of solid hydrogen will prove to be nearly correct. Allusion was then made to Graham's opinion that the various kinds of matter now recognised as different elementary substances may possess one and the same ultimate or atomic molecule existing in different conditions of movement, the varying degrees of rapidity of this movement constituting, in fact, the difference between the elementary bodies. In other words, if the molecular energy of a so-called element could be changed, the element would be dissociated, a view of special interest in relation to the researches of Lockyer. The lecture was illustrated by many effective experiments, and concluded with the statement that it had not been instituted from the merely special interest of Graham's researches to the physicist and chemist, but in honour of the labours of a life, the memory of which will be as enduring as its work, and to stimulate others to investigate as patiently and earnestly the varied phenomena whose basis is "Molecular Mobility."

— Sir WILLIAM THOMSON, in proposing a vote of thanks

to the Lecturer, called attention to a diagram on the wall recording the rates of passage of gases by diffusion, effusion, transpiration, and by the peculiar passage through such "colloid septa" as non-crystalline metals or india-rubber; and he stated that before Graham's time these valuable physical constants were absolutely unknown. They had listened with much interest to the connection which had been traced between Graham's law of diffusion and the science of molecular physics, as well as to the account of Graham's work generally, so carefully set before them by Graham's pupil and friend.

PROCEEDINGS OF SOCIETIES.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, December 24, 1878.

J. P. JOULE, D.C.L., LL.D., F.R.S., &c., President, in the Chair.

'Note on the Intensity of Moonlight,' by HARRY GRIMSHAW, F.C.S.

At the meeting of this Society held on the 26th of November, 1878, some remarks were made upon the relative intensity of moonlight, daylight during a thick fog, and the diffused light of the electric arc.

The opinion was then expressed by some members that it was very doubtful whether it was possible to read printed type of anything like a small size by the brightest moonlight in this country.

The light of the moon on the 8th of December being of considerable intensity, I took the opportunity of making the experiment, which I have previously, at different times, performed more roughly, with sufficient accuracy to form some standard of comparison. The result was that I found it possible to read with certainty a still smaller type than I had previously known it possible to peruse.

The types on which I experimented were those of a newspaper, and known technically by the printers as "minion," "bourgeois," and "nonpareil." These are all smaller than the letters of the *Proceedings* of the Society, which I believe is called "small pica." The first two are what are ordinarily used for such printing as that of newspapers and the cheaper periodicals, whilst the last ("nonpareil") is a very small letter indeed. The last paragraph of this note is printed in the type in question. The printed matter in the "minion" and "bourgeois" letter was read with comparative ease; the "nonpareil" had to be perused slowly, but could be made out with certainty.

The time at which the above experiment was performed was 8.15 p.m., and the evening of course bright and cloudless. The moon was full at 7.49 p.m. the following evening. The observers were three in number, who all succeeded in reading the three types, and it should perhaps be added, as a quantity affecting the results, that the "eyes" were all comparatively young, being under the age of thirty.

CORRESPONDENCE.

WATER ANALYSIS.

To the Editor of the Chemical News.

SIR,—I have perused with much interest Dr. Tidy's valuable paper on "Water Analysis," published in the January number of the *Journal of the Chemical Society*, and am of opinion that he has done good service in drawing attention to the most accurate methods to be adopted in the examination of waters, more especially to the employment of the two-foot tube and the action of permanganate during the first hour.

The point which still remains to be discovered, however, is where to draw the line; this is the main question, and

is by no means decided by any paper on water analysis yet published. For years past our text-books, both English and foreign, have stated that when the total impurities of a sample of water reach beyond a certain figure the water is to be condemned. But this is a mere assertion which has been copied from one book into another for the last thirty years or more. The fact is, we possess at present no positive data whereby to condemn a sample of drinking-water, and cannot possess such data until physiological experiments have been made to prove when and why a given kind of water is bad or good. In most cases it is not difficult to prove a water good for drinking, but quite the reverse to establish that it is injurious to health or unwholesome, unless it be very bad indeed.

What the chemist requires is to be able to state with certainty that a water which discolours so much permanganate in an hour is unwholesome. How much permanganate of a given strength may a water discolour and yet be good for drinking? That is a point of the utmost importance, which Dr. Tidy's laborious and interesting investigations have not solved any more than his predecessors' in the same branch of research have done. Of the hundreds of analyses which pass through my hands every year there are none which give me so much trouble and anxiety (I can use no other word) than drinking-waters. Let us suppose that the ingredients of a well-water consist of carbonate of lime, 25 grains; sulphate of lime, 18 grs.; nitrates and chlorides of magnesium, calcium, and sodium, 20 grs.; organic matter, 7 grs.; total, 70 grs.; and that the microscope shows neither microphytes nor animalculi in the water or slight deposit it may leave on standing; that the 7 grains of organic matter consist almost entirely of crenate of ammonia which can be separated by alcohol. Is such a water unwholesome to drink? If so, why? Now let us suppose that these 7 grains of organic matter are some putrescent matter in a state of decomposition. Would the water then be injurious to health? I must confess that we have no positive answer to this important question. (And 7 grains of organic matter is more than is present in the great majority of waters used for drinking.)

The thing to be determined is, as I said before, where to draw the line. On what authority are we to condemn a water as unfit for drinking? Perhaps the permanganate solution as used by Dr. Tidy may help to solve the problem. The questions which require to be solved are apparently very simple:—

- (1.) How much organic matter in a putrescent state (*i.e.*, how much permanganate in the hour) may be tolerated in a specimen of water before that water is condemned as unfit for drinking?
- (2.) How much nitrates and chlorides may be present in a gallon of water before this water is pronounced unwholesome?

These questions cannot be answered by mere supposition or conjecture.

Let me recommend these points to medical men who are devoting themselves to the examination of drinking-water.—I am, &c.,

T. L. PHIPSON, Ph.D., F.C.S., &c.
Laboratory of Analytical Chemistry,
Putney, London, S.W.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 1, January 6, 1879.

Reply to M. Pasteur.—M. Berthelot.—The author points out that the posthumous papers of Claude Bernard

contain merely the beginnings of a series of experiments. The question was not to open a polemic on a train of research interrupted by the death of its author, but to preserve the trace of it in science. As to M. Pasteur's theory that certain organisms derive combined oxygen from sugar instead of free oxygen from the atmosphere the burden of proof rests with him and not with dissidents.

Formation of Organic Ultramarines.—M. de Forcrand.—The author concluded that it might be possible to obtain organic ultramarines by heating silver ultramarine with the chlorides or iodides of the alcoholic radicles. He caused an excess of hydriodic ether to react upon silver ultramarine for fifty to sixty hours at 180° in a closed vessel, and obtained thus an ethyl-ultramarine in the form of a grey powder.

Separation of Ethyl-amines.—E. Duvillier and A. Buisine.—By the process which the authors have adopted they succeed in separating di-ethyl-amin as a perfectly crystalline body. The methyl-amins appear to act in the same manner.

No. 2, January 13, 1879.

Researches on Ozone and the Electric Effluve.—M. Berthelot.—Hydrogen and oxygen mixed in the proportions of two vols. of the former to one of the latter, do not combine under the influence of the effluve, whether in sealed concentric glass tubes or in a tube surrounded with a lamellar spiral of platinum and placed over mercury. The tension of these experiments was about equal to that which gives sparks of 7 to 8 centimetres in length through air when operating with an induction coil fitted with condensers. Doubtless on increasing the tensions progressively nearly up to those which produce disruptive discharges water would be formed. But it is important to show that this formation does not ensue with tensions such as the above and in conditions where a very notable quantity of ozone is produced. The resistance of hydrogen to combination under these circumstances is so much the more remarkable as the conditions are precisely those in which oxygen combines with metals, with sulphurous and arsenious acids, iodine, and even with nitrogen. Vapour of water is not decomposed by the effluve in these conditions, and oxygen does not combine with water to form hydrogen peroxide. On the other hand, carbonic oxide and oxygen combine under the influence of similar electric tensions, though even in presence of an excess of oxygen a portion of carbonic oxide remains uncombined. Reciprocally it does not prevent the incipient decomposition of carbonic acid, and in a mixture of equal volumes of carbonic acid and oxygen after twelve hours 5 per cent of the gas was decomposed into carbonic oxide and oxygen. This oxygen contained a very strong proportion of ozone or of percarbonic acid. The decomposition of pure carbonic acid by the effluve, effected in a space free from mercury and from oxidisable bodies, gives rise to special phenomena very worthy of interest, as they lead us to suspect the existence of percarbonic acid. The gas formed attacked mercury with extreme violence. It may be considered either as oxygen very rich in ozone or as containing a strong dose of percarbonic acid, C₂O₆.

Formation of Ethers of Hydracids in the Gaseous State.—M. Berthelot.—The author gives some new determinations to permit the calculation of the heat disengaged by the gaseous products of the union of the carbides of hydrogen with the halogens and the hydracids.

Are there among the Lower Species with which we are Occupied Species Exclusively Aerobian and others Exclusively Anaerobian? Are all these Beings to be Ranked in Two Classes, or in Three as M. Pasteur has Successively Admitted, or in One, as I have Recently Indicated?—M. Trecul.—The author concludes that organised ferments are merely particular conditions of species more or less complicated, which are modified according to the media they inhabit.

Instead of three classes of inferior beings, according to the present views of M. Pasteur, we must recognise one only, each species being able to present one or more ærobian and one or more anerobian conditions.

Second Reply to M. Berthelot.—M. Pasteur.—A continuation of the controversy springing from the posthumous writings of Claude Bernard.

Researches on the Compressibility of Gases.—L. Cailliet.—The author describes the improved manometer used in his recent researches. He finds that nitrogen is compressed at first more than is indicated by Mariotte's law, and that its compressibility then decreases, as he found to be the case with atmospheric air in his earlier researches. Nitrogen presents this curious maximum at about the pressure of 70 metres of mercury.

A New Compound Prism for Direct Vision Spectroscopes, having a very great Dispersive Power.—A. Thollon.—The sulphide of carbon prism presented to the Academy possesses an extraordinary dispersive power. Instead of being enclosed laterally by plates with parallel surfaces, it is enclosed by prisms of crown glass whose refrangent angles are in an opposite direction to that of the sulphide. The refrangent media are distributed as in the prism of Amici, with this difference, that the angles of the crowns are smaller, and that at entrance as well as at exit the luminous ray passes always between the summit of the angle and the normal at the surface. This system is intermediate between the simple prism and the direct vision prism, the deviation being less than in the former and the dispersion greater than in the latter. The absorption is almost annulled.

Thollon's Spectroscope.—L. Laurent.—A further description of this apparatus. Its dispersion is equivalent to that of four flint prisms of mean density.

Synthesis of Uric Derivatives of the Alloxanic Series.—E. Grimaux.—The direct product of the action of phosphorus oxychloride upon a mixture of malonic acid and urea is malonyl-urea, the barbituric acid of Baeyer, mixed with a yellow amorphous substance, sparingly soluble in water.

Action of Diastase, Saliva, and Pancreatic Juice upon Starch and Glycogen.—F. Musculus and J. de Méring.—Saliva and pancreatic juice yield with starch the same decomposition products as diastase, namely, reductive dextrines, maltose, and glucose. Glycogen yields similar products, but its dextrines are less hygroscopic than those of starch, and their reductive power is less. There is only one glycogen, whether the animal producing it has been fed exclusively on the hydrates of carbon or on albuminoid food. The existence of reductive dextrines of variable power accompanying maltose and glucose proves the necessity of having recourse to fermentation in the determination of sugar in industrial products, and explains the discordant results obtained by experimentalists. [This memoir is, curiously enough, placed under the heading "Inorganic Chemistry."]

Les Mondes, Revue Hebdomadaire des Sciences.
No. 15, December 12, 1878.

M. Maurice Perrin points out that the physiological effects of chloroform at present are much less satisfactory than was the case some years ago. He considers that less care is employed in its manufacture.

The process adopted by M. Coquerel, of the Clichy Manure Works, is said to have succeeded in instantly converting excrementitious matters into an inodorous cake, containing 3 per cent of nitrogen and 10 per cent of phosphoric acid.

Note on the Phylloxera.—M. Carves.—The author maintains that the Phylloxera *per se* is not the cause of the death of the vine, the real enemy being a fungus which plants itself in the wound made by the animal.

MISCELLANEOUS.

The Royal Institution of Great Britain.—At the General Monthly Meeting held on Monday, February 3, 1879, Warren De la Rue, D.C.L., F.R.S., was elected Secretary of the Royal Institution, and William Spottiswoode, D.C.L., Pres. R.S., was elected Manager.

NOTES AND QUERIES.

Ammonia Tables.—Can you inform us if there are any tables published of liquor ammonia strengths, taking into consideration the different temperatures as well as the specific gravity? For instance, if liq. am. is 0.895 at 35° F. what sp. gr. will it be at 60° F., and *vice versa*? We find that all the tables in Watts, Ure, and Miller always suppose the temperature to be 60°, but as we bottle at all temperatures it would assist us if we had a table that could be relied upon.—W.R.E.

MEETINGS FOR THE WEEK.

SATURDAY, 8th.—Physical, 3. "Variation of the Thermal Conductivity of a Rod with Temperature," Dr. O. J. Lodge. Annual General Meeting.
MONDAY, 10th.—Medical, 8.30.
London Institution, 5.
Royal Geographical, 8.30.
TUESDAY, 11th.—Civil Engineers, 8.
Photographic, 8. (Anniversary).
Royal Institution, 3. "Animal Development," Prof. Schäfer.
Anthropological, 8.
WEDNESDAY, 12th.—Society of Arts, 8.
Microscopical, 8. (Anniversary).
THURSDAY, 13th.—Royal, 8.30.
Royal Institution, 3. "Sound," Prof. Tyndall.
Royal Society Club, 6.30.
FRIDAY, 14th.—Royal Institution, 9. "November Meteors," Prof. Johnstone Stoney.
Quekett, 8.
SATURDAY, 15th.—Royal Institution, 3. "Lessing," by Reginald W. Macan.

TO CORRESPONDENTS.

J. A. Fahie.—We regret we cannot give our correspondent the information he requires.
S.—You had better write direct to the Professor and ask the question.

THE CHEMICAL NEWS.

Vol. XXXIX. No. 1893.

THE DISSOCIATION OF THE ELEMENTS.

It has fallen to the lot of modern chemists to witness a discovery in their science which, if duly verified, must be pronounced of importance almost beyond parallel. The formation of endless compounds, the speculations on their "constitution," the synthesis of organic bodies, the detection of new metals,—all, in short, that can be done with or deduced from the isolation and combination, the arrangement and re-arrangement of the so-called elements, falls into a secondary position in comparison with the complete reversal of our accepted notions concerning those elements themselves. It is therefore incumbent upon us all to rise to the level of the occasion. We must neither, in view of the dazzling prospect thrown open before us, give too free rein to the "scientific imagination," nor should we carry scepticism further than candour sanctions and than the interests of Science require.

It can scarcely be denied that some among us have sinned in both these directions.

In considering the evidence laid before us in support of the decomposition of our present elements, we must remember that the discovery does not break upon us unannounced and unprepared. Whoever has heedfully dwelt on the philosophy of chemistry must admit that, as research has been pushed further and further, the primary and indecomposable character of those sixty odd bodies which we have been taught to call simple has been rendered more and more doubtful. If we consider their comparative properties we find groups which present such features as might be expected from a compound formed by some body, x , with successively increasing proportions of another, y . But we should be compelled almost to write the history of chemistry from the beginning of the present century were we to enumerate all the phenomena and all the considerations which caution us against ascribing to the "elements" more than a merely provisional character. As Mr. Lockyer judiciously points out, with the application of increasing temperatures we have increasing dissociation, and on the faith of the principle of continuity we may expect that still higher temperatures will act in the same direction as lower ones have already done. The only reply is, that hitherto we have had no satisfactory proof that this has been done in any one instance. This difficulty Mr. Lockyer's recent researches seem to have overcome. It is a matter of some importance to note that these researches were not undertaken in the hope of decomposing the elements. The object in view was a knowledge of the chemical nature of the sun, in pursuit of which the observer was compelled to form his present conclusions. It will not be necessary or us to recapitulate the evidence which has been given in detail in the CHEMICAL NEWS for January 3rd and 10th of the present year. We will merely cite the experimental conclusions that "the common lines visible in the spectra of different elements at high identical temperatures point to a common origin, and that the different lines visible in the spectra of the same substance at high and low temperatures prove that at the former dissociation goes on as continuously as at all lower temperatures."

All this, however, it may be objected, is not direct experimental evidence, analytic and synthetic, such as chemists are able to produce in favour of the compound nature of water. Mr. Lockyer has not, *e.g.*, taken a gramme of copper and decomposed it, exhibiting, in a state of isolation and in due proportion, each of the various more elementary elements of which it is com-

pounded, and again reconstructing the original metal from these materials. Still less has he realised the dream of the alchemists by transmuting one metal into another. But if we are on this account to refuse to his hypothesis that fair examination to which it is so well entitled, we are establishing a dangerous precedent, and incurring the charge of gross inconsistency. Who, for instance, has seen and handled an atom, or even a molecule? Yet we admit the existence of such portions of matter, we ascribe to them certain properties, and we even speculate on their relative positions in complex bodies, because by so doing we can, to the best of our knowledge, most satisfactorily explain certain phenomena. This is precisely the evidence in favour of the undulatory theory of light or of the kinetic theory of gases. They are accepted as best accounting for the facts of the respective cases. Just so with Mr. Lockyer's hypothesis of the dissociation of the elements; it explains, with a completeness hitherto unattained, a number of difficulties in solar and stellar physics. If we admit that "the solar phenomena in their totality are due to dissociation at the photospheric level, and re-association at higher levels," we can then understand the ascending and descending vertical currents in the solar atmosphere, the absorption in sun-spots, and their association with the faculæ, as well as the seemingly continuous spectrum of the corona and its peculiar structure, the excess of supposed calcium in connection with minimum sun-spots, and, contrarywise, the connection between an excess of so-called hydrogen with a maximum of sun-spots.

Even at present, therefore, until some fact is shown to be irreconcilable with Mr. Lockyer's views, we consider ourselves perfectly justified in giving them our provisional adhesion, as a working hypothesis to be constantly tested by reference to observed phenomena.

As regards what may be called laboratory verification, there is a difficulty in the way which at first sight may seem insurmountable.

Let us suppose that we have volatilised and dissociated an element, say copper, and that we have, floating in the voltaic arc or in any other region of intense artificial heat, the vapours of its unknown constituents, which we may call x and y . The problem is to withdraw these vapours from the arc and from each other without allowing them the opportunity of re-associating and so re-constituting the original copper. If we allow the temperature to decline, this result must, it should appear, inevitably follow. But suppose we volatilise and dissociate two or more elements together; is it not at least conceivable that on re-association they might form new combinations? Thus, suppose we have a vapour mixture of—

Is it not possible that x might combine not with y but with y' or y'' , forming bodies which it would be easy to distinguish from the alloys and other compounds of our reputed elements. It will be of course desirable to submit all our simple bodies to degrees of heat higher if possible than have ever been attained before and under every conceivable modification of circumstances. Above all, spectroscopic research will have to be instituted and scrutinised from this novel point of view. Perhaps by some of these methods we may succeed in penetrating to a deeper, a more fundamental series of elements to which our present supposed simple bodies stand in the relation of mere compounds, and of scrutinising their relations and studying their combinations.

But even if it is not given to man to advance farther than a mere knowledge that our present elements are not ultimate and primary species of matter—and this is all to which Mr. Lockyer, so far, lays claim—it is scarcely possible to over-rate the value of the discovery. Our views of the constitution of the universe are rendered far grander and broader. The atom instead of being, as was

recently thought, a "manufactured article" alike throughout the universe and incapable of change is now seen to depend for its nature and very existence upon the thermic condition of its medium. The elements of the planet are decomposed in the sun to a degree dependent upon its temperature. And perhaps the bodies which there resist all further change, and would to a rational being capable of inhabiting our central orb appear as simple, may be decomposed in hotter stars, or in that great body round which, as some astronomers tell us, all the heavenly bodies are describing a revolution. On the other hand, in planets colder than our earth bodies which we are capable of resolving into components might prove apparently elementary. The "elements" in each planet, comet, and sun are therefore the result of a process not altogether heterologous to the "struggle for existence" which eliminates from our earth all organic forms not in harmony with its general conditions; and from this point of view Mr. Lockyer may be saluted as the Darwin of the inorganic world.

A NEW TEST FOR COBALT.

By T. TATTERSALL.

If a solution of a cobalt salt be mixed with cyanide of potassium, a cinnamon-coloured precipitate takes place, the precipitate, as is well known, being soluble in a slight excess of the reagent to a clear yellow liquid. But if now a few drops of yellow ammonium sulphide be added, a blood-red colour is obtained, even in presence of nickel salt, or any soluble cyanide except the copper compound, which completely prevents the reaction. Colourless ammonium sulphide will not produce the red colour. It may also be obtained, though not with the same degree of delicacy, by using Na_2SO_3 or SnCl_2 .

VICTOR MEYER'S NEW METHOD OF DETERMINING VAPOUR-DENSITIES.

By WATSON SMITH, F.C.S., F.I.C.

I HAD been for some time looking out wistfully for a truly reliable and accurate method, and one not possessing too much intricacy and risks of failure, for the determination of the vapour-densities of the highest boiling hydrocarbons, wherewith I should be able to settle once for all any possible question as to the molecular integrity of the bodies I had considered to be isomeric dinaphthyls. This want has just recently been supplied in the most complete manner, and the point mentioned quite settled, by means of a method so simple, universally applicable, easy and rapid of execution, and withal accurate, that it deserves a foremost place amongst scientific methods. Especially for the worker in the fields of original research will this method indeed be a great boon, and, in fact, amongst methods of its kind, will no doubt take the very first place. Prof. Victor Meyer, of Zürich, has for some time been working upon and perfecting methods of vapour-density determination. The present method is the improved form of one described in the *Deut. Chem. Ges. Ber.*, xi., 1867, and is described by V. Meyer and Carl Meyer in the *Deut. Chem. Ges. Ber.*, xi., 2253 (*i.e.*, the last issue). I have been astonished with the accuracy of the results this method yields, considering the celerity and ease of the determination, and I thought it would be doing good service to help to spread the news of the discovery of a method of vapour-density determination scarcely requiring more time or trouble than the determination of a melting- or boiling-point. With this method the temperature of the bath and the size and contents of the vessel employed do not need to be considered in the calculation.

b (Fig. 1) is the specific gravity vessel of glass, containing 100 c.c., and about 200 m.m. high as regards the cylindrical lower part. The stem above is about 600 m.m. high. d is a caoutchouc stopper closing and fitting well above. a is a narrow, almost capillary, evolution-tube, through which the air escapes in the process, and bubbles up into the graduated tube, e, filled with water, and standing in the little pneumatic trough of glass, f, over water. At the lower part of the apparatus, which must be perfectly clean and dry to begin with, a little asbestos is placed to break the fall of the little glass tube, g, with weighed substance, which at the proper time is dropped in at d. The bath of glass, c, for bodies boiling up to 300°, may be furnished with water, xylene, aniline, ethyl benzoate, amyl benzoate, or diphenylamine, according to the boiling-point of the

substance determined. And these bodies do not need be pure. It is only requisite, in short, to know that the bath furnishes a uniform and constant temperature sufficient easily to vapourise the substance. The substance is weighed out in a little tube, open at one end, and the amount taken should be such that its vapour will occupy somewhat less than half the volume of the cylindrical part of the apparatus, b (fig. 1). The glass bath, c, is placed on wire gauze and heated with a Bunsen's burner. If the substance boil over 300°, then the lead bath (fig. 2) is used. This is merely an iron tube, mounted on three legs. Pieces of lead are thrown in and melted by the heat of a large Bunsen's burner with fifteen jets. To prevent the glass cylinder from touching the iron sides of the tube it is enclosed in a sort of wire cage, as in fig. 2 (s). The apparatus must be cautiously and gradually introduced into the lead bath, else it is cracked or broken. When the lead bath is employed the requisite temperature for vapourising the substance is ascertained simply by placing a little of the substance in a narrow test-tube, and dipping this under the surface of the molten lead, and both observing and applying the ear and listen-

ing if it boils. This is most simply and easily ascertained. The remainder of the process is the same whether lead bath or any other be employed. The instrument, into which a little well-ignited asbestos has been introduced, is gradually and carefully introduced into the bath and fixed in position, the end of its fine tube dipping sufficiently deep below the water in the little trough. The graduated tube stands close by, filled with water and inverted in the trough. The cork, *d*, is now inserted, and it is necessary to wait till the little column of water, extending a m.m. or two up the fine evolution tube, remain quite stationary, no more bubbles and no further motion occurring. This is a sign that a uniform temperature obtains within. The cork is now taken out, and the little tube with substance dropped in, and the cork quickly replaced again, whereby a bubble or two of air escape by displacement. These are not heeded, but immediately afterwards the inverted tube is placed quickly over the point of the evolution tube, *a*. Very soon the substance below is vapourised, and displaces the air of the apparatus above, which issues in a rapid stream of bubbles into the graduated tube. This evolution at an end (generally occupying 10 to 15 seconds), the little water column will first assume a tranquil condition; others gradually show signs of receding. It will recede after some little time a certain distance up the narrow tube, *a*, the effect of diffusion, set up below, between vapour and air. As soon as the gas evolution is over the cork is removed, the thumb placed over the orifice of the graduated tube, and the latter removed and completely immersed in a large deep cylinder filled with water and containing a thermometer. The barometer and thermometer in the water are now, after waiting a minute or two, read off, and then all observations are at an end. The following simple formula gives the vapour density—

$$D = \frac{S \cdot 760(1 + 0.003665t)}{(B - w) V \cdot 0.001293}$$

or gathering together the constants—

$$D = \frac{S(1 + 0.003665t) \cdot 587780}{(B - w) V},$$

where—

S = weight of substance.

t = temperature of water in cylinder, *i.e.*, of the room.

B = Barometric column reduced to 0°.

w = tension of aqueous vapour at *t*°.

V = measured volume of air, in grad. tube.

In the case of substances slightly decomposed by atmospheric air at their boiling and vapourising points, dry nitrogen gas is introduced into the apparatus, and the vapour density is thus determined in nitrogen. *V. Meyer* prepares the nitrogen according to the Gibbs-Böttger method by boiling a solution of 1 part potassium bichromate, 1 part ammonium nitrate, 1 part commercial sodium nitrate, and in 3 parts of water. The gas was also passed over a layer of ignited metallic copper before conducting into the gasholder. From the gasholder it passes first through drying tubes, and then down a long narrow glass tube reaching to the bottom of the vapour density apparatus, itself perfectly clean and dry. The instrument is thus filled by displacement and most simply and expeditiously.

The wide range of this apparatus is shown in the numerous examples of determinations made by Prof. *V. Meyer's* assistant, Herr Carl Meyer, by its means. Chloroform boiling at 61° is first determined (in steam), and, lastly, in the lead bath, the perchlor-diphenyl of Merz, boiling considerably higher than 440°. This determination was made in an atmosphere of nitrogen.

Results.

	Calc.	Found.	Boiling pts.
Chloroform (in steam)	4.13	4.13	61°
Perchlordiphenyl (in nitrogen and lead bath)	17.24	17.43	over 440°

To demonstrate the great value of the method for ascertaining the molecular weights of certain high boiling hydrocarbons, whose compositions may lie so closely together that the centesimal numbers obtained by an organic combustion will fail to distinguish them, it may just be mentioned that the body chrysene, $C_{18}H_{12}$, as regards the numbers furnished by organic analysis, cannot be distinguished from dinaphthyl, $C_{20}H_{14}$. The calculated vapour densities of the two bodies are respectively 7.89 and 8.77. The numbers found by Victor Meyer's method were—for chrysene, 8.12; ditto for dinaphthyl, 8.73. (I am told the substance was not quite pure.)

I am told the apparatus for the above method is to be had on application to Herrn H. Fischli, Zürich, Rami-strasse 45.

Zürich, Feb., 1879.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, February 6, 1879.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

AFTER the announcement of visitors, the minutes of the previous meeting were read and confirmed.

The Treasurer, Dr. RUSSELL, then announced that he had received a bequest of £1000 from the executors of the late Mr. Sidney Ellis, of Nottingham.

The following certificates were read for the first time:—
A. W. Stokes, T. L. Teed, C. H. Hutchinson, G. Rait, W. Stone, T. Griffiths, W. Palmer.

During the meeting the following gentlemen were balloted for and declared duly elected Fellows of the Society:—F. R. Japp, C. F. Cross, H. Wilson, C. E. Cassel, A. E. Menke, J. J. Broadbent, E. A. Letts, E. H. Rennie, W. Stevenson, S. Spencer, C. W. Smith, A. J. G. Lowe, T. Gough, R. Gracey, P. P. Bedson.

The PRESIDENT said that it was scarcely necessary to remind the Fellows that the discussion on Dr. Tidy's paper had been adjourned to this evening, and that it was his duty to preside over the champions of the three processes for determining the organic matter in potable waters, and to see—if he might be allowed the expression—that the lists were clear and the fight was fair. The question to be discussed this evening was that of the relative merit of the processes, and there was the question behind, viz., how far these processes tell us whether a water is fit to drink or not. It was one thing to determine the carbon and nitrogen, and quite another to decide whether such quantities so detected were hurtful or not. He should like to mention that two curves which formed part of Professor Tidy's paper had not been published with the letterpress on account of the delay which had arisen during some corrections. The curves would be published in the forthcoming number. He would call on Mr. Riley, as he moved the adjournment, to open the discussion. Mr. Riley, however, not being present, Dr. Frankland opened the discussion.

Dr. FRANKLAND said that in responding to the President's invitation to open the discussion he wished to express the gratification which the perusal of Dr. Tidy's paper had afforded him. The author had performed his task in a truly philosophical spirit, with fairness and candour. He had frankly told us of the alteration of some of his former opinions, and, above all, he had contributed a large amount of important and laborious work to the subject of water analysis. He thought that chemists generally were much indebted to Dr. Tidy for the clear and impartial style in which he had handled an intricate and exciting theme. As he would have to criticise some parts of the paper

adversely he wished to record at the outset his very favourable opinion of it as a whole. To proceed with the details of the paper, he quite agreed with the author that if it were possible to estimate the organic matter in the water before evaporation, such a mode of estimation would be preferable to any operations of the kind upon a water residue; but unfortunately he knew of no method by which this could be accomplished. He also agreed with the author's opinion that potable waters contained a great variety of organic matters, although he would not go so far as to say that the variety was "infinite." He entirely dissented, however, from the author's suggestion that non-volatile matter may be removed *mechanically* during evaporation. He had proved by actual experiments that mechanical removal only took place during violent agitation or the breaking of gas bubbles at the surface of the liquid. The opinion that solid or liquid particles were mechanically removed during quiet evaporation was emphatically negatived by almost every quantitative determination in analytical chemistry. He was still more astonished, however, to find Dr. Tidy, who is a physician as well as a chemist, suggesting that the poisonous constituents of sewage may be volatile:—"Remembering how virulent that poison is, I should myself be far from astonished if it were of a highly volatile nature, just as we know that arseniuretted hydrogen far exceeds arsenious acid in intensity of action on the human body." All the knowledge we have hitherto acquired about the infectious matter of epidemic disease points to the inevitable conclusion that the propagating material is not merely organic, but organised; and that its virulence, unlike that of arsenic or other similar poisons, resides in its vitality and its power of multiplying itself almost indefinitely in the human body. Now it is impossible to conceive of organisation in substances whose molecules are free to move as they list:—An organised liquid, gas, or vapour, is a physical impossibility, and hence there is no foundation whatever for the opinion that the poison of sewage is volatile, or that it is not contained in the residue left on evaporation. Indeed, the author, somewhat inconsistently, admits this generally-accepted view of the nature of morbid poison when he says, soon after making the foregoing suggestion,—"But it must be remembered that the evils arising from drinking contaminated water are probably the work of invisible particles—germs or whatever else you like to call them." We cannot, however, estimate separately the *disease producing* organic matter of polluted water. It is probably, even in the worst waters, so small in quantity as to be almost imponderable. Dr. Tidy appeared to be equally inconsistent in his great fear of loss of organic matter by oxidation in a *reducing atmosphere of sulphurous acid*, when he afterwards went on to show the extreme difficulty of oxidising such organic matters by an *acidified solution of potassic permanganate*! Moreover, the oxidation of organic matter by no means necessarily increases its volatility. The difficulty which the author has occasionally expressed in the reduction of nitrates when these salts occur in large quantity appears to have arisen from his fear of oxidation by sulphurous acid, and his consequent neglect of the precautions given. He says, "I cannot conceive that the organic matter in the residue can survive direct actual treatment with a sulphurous acid solution. I never do this part of the experiment without a feeling of despair." This conception and this feeling were, however, utterly opposed to facts. Hundreds of combustions of the residues of shallow well-waters containing large quantities of nitrates have demonstrated that the organic matter does survive this treatment. Moreover, this difficulty is in practice more imaginary than real; for when a water contains these excessive quantities of nitrates, it is to be condemned on this ground alone. With regard to the remaining obstacles mentioned in connection with the combustion process, it is easy to procure suitable cupric oxide, either by oxidising sheet-copper in a muffle, or by procuring roasted copper scraps from the makers of sulphate of

copper. The speaker always procured these scraps from Messrs. Tennants, London Road, Manchester, and it was only necessary to heat them to redness in an iron tube for an hour or so in a current of air to fit them for use. There cannot be any occluded nitrogen in the copper, as suggested, because the copper is always heated to redness *in vacuo* before the combustion begins. The author is now convinced of the accuracy of the determination of organic carbon, and the speaker confidently anticipated that further acquaintance with the combustion process would prove to him that the corresponding determination of organic nitrogen was quite accurate enough for all practical purposes. With regard to the albuminoid ammonia process, his experience coincided with that of Dr. Tidy. It had been put forward as capable of answering the question, "Is the water wholesome or is it not?" It does not, however, answer this question: It condemns water containing only peaty matter, and it acquits water containing urea and uric acid! If we look at the results of its application to the waters supplied to London and recorded in this paper, could anybody believe that in 1876, for instance, the Chelsea Company's water, drawn from the Thames, was "safe" in January, "dirty" in March and August, "safe" again in November, and "of extraordinary purity" in December, when it contained no less than 0.423 part of organic elements in 100,000 parts of water; and when three other samples drawn from the same source were denounced as "dirty" by the same process. Again in 1871, whilst the West Middlesex Company's water was "of extraordinary purity" in January, April, and May, the Chelsea Company's water was "dirty" in those months, although quite "safe" in December. Floods undoubtedly make Thames water dirty, but the albuminoid ammonia curve pursues the even tenor of its way quite regardless of them. The very instructive comparative curves, given at the close of the paper, prove conclusively that there is no sort of connection between the pollution of water and the proportion of so-called albuminoid ammonia. He now came to the most important part of the paper, viz., that treating of the oxygen or permanganate process. Experiments had recently been made in his laboratory by Mr. Woodland Toms which showed that there was not, as suggested by the author, any substantial difference between Dr. Tidy's method of performing this process and his own, which was that originally described by the late Dr. W. A. Miller. The author speaks of this process as if by it "everything capable of oxidation" was completely oxidised. But there must be some mistake here, because of the numerous organic matters hitherto submitted to it oxalic acid was the only one completely oxidised. The author had made numerous experiments on the influence of various mineral salts upon the test, and he had shown that the presence of nitrates made no difference with its indications. It was far otherwise, however, with sulphuretted hydrogen, ferrous salts, and nitrites. The first two were easily detected and removed, but the nitrites presented a formidable difficulty, which, in the speaker's opinion, the author had not overcome. He (Dr. Frankland) admitted that they were not often present in potable water; but unfortunately they were especially liable to be present in well-waters, and the oxygen process might thus condemn deep well-waters of most excellent quality. The author's own figures, obtained with the Kent Company's deep well-water, showed this, especially when the very erratic curves of this very uniform water were studied. Thus, in 1870, for instance, the oxygen consumed by this water varied from 0 to 50, whilst the organic elements varied only from 1 to 3.3. In 1871, the oxygen consumed varied from 1 to 7, but the organic carbon and nitrogen only from 1 to 2.6. In 1874, the oxygen consumed was remarkably and uniformly low, whilst the combustion results were, for this water, remarkably and uniformly high. Again, in 1875, the oxygen consumed varied from 1 to 7, but the organic carbon and nitrogen only from 1 to 2; and, lastly, in 1876, the oxygen consumed varied from 1 to 3, but the

organic elements only from 1 to 3. There is a strong probability that the organic matter in the Kent Company's water is acted upon but very slightly by permanganic acid, and that the effects recorded by Dr. Tidy were chiefly produced by nitrites. The speaker had observed on one occasion that a sample of this water, on its first arrival at his laboratory, consumed three times as much oxygen as it did after standing a couple of days, although he had proved that the organic matter in this water underwent no diminution during eleven days' agitation with atmospheric air. Nevertheless there was undoubtedly a remarkable approximation between the curves representing for many years the organic carbon in the river waters supplied to London and those recording the oxygen taken up from potassic permanganate; and the speaker was not without hope that as a short and easy cut to the valuation of organic carbon the process might be made available for potable waters generally, but he thought the author had, as yet, failed to establish it in this position. There were also some other remarks about the capabilities of the oxygen process, which must not pass unnoticed. Dr. Tidy admitted that it certainly does not affect all organic substances; but he says it "affords the most positive evidence (evidence to my mind beyond dispute) of the relative quantity of matters in the water likely to be injurious (for it is the offensive and deleterious we wish to hunt out, and not the inert and the harmless), and enables us to speak with confidence in advising the use of, or the rejection of, a water for drinking purposes." Where is the evidence of this beyond dispute? Dr. Tidy has not given us the slightest fragment of it. If it exists it ought to be produced, because it would put the oxygen process upon the firm and trustworthy basis which it, at present, certainly lacks. No process of water analysis can distinguish between "offensive and deleterious" and "inert and harmless" organic matter; but there is a method which can take account of starch, sugar, gum, gelatine, uric acid, and urea. Dr. Tidy said, and he quite agreed with him, that these substances are in themselves quite innocuous; but how do they get into potable water? People are not in the habit of throwing sugar, starch, gum, or gelatine into rivers. There is a sufficient observance of the proverb "Waste not, want not" to prevent such a use of these valuable materials. Care is taken that these substances first pass through a canal before they reach a river, stream, or well, and that canal is the alimentary canal! Will Dr. Tidy assert that these substances embalmed in the secretions of that canal are *ever* fit for human consumption, or are not, at times, charged with the potentiality of disease? Hence he (Dr. Frankland) said that no process of water analysis is trustworthy which does not take full account of these substances, inert and harmless though they may be, when they leave the grocer's shop. Another statement in the paper in reference to the oxygen process ought not to pass unchallenged, although the author had ceased to act upon it. He said, "In the case of the London waters, however, I think I have abundant experiments to prove that the oxygen used, multiplied by eight, denotes very nearly the actual quantity of organic matter present; nor would it be difficult to obtain further evidence (if it were required) on this point from the work of others." Will Dr. Tidy mention the details of some of these experiments? To chemists generally there is no method known by which "the actual quantity of organic matter present" in London water can be even approximately determined. How, then, can that quantity be proved? If the author knows of a process why does he not disclose it? Such a discovery would go far to sweep the oxygen, albuminoid ammonia, and combustion processes into oblivion, for it could scarcely fail to be equally applicable to other waters besides those consumed in London. With regard to the adjuncts to the oxygen process, the speaker remarked that he considered the colour test to be useful only from a sentimental point of view. Comparatively few organic

matters are coloured, and the coloured part of the organic matter of water is probably a very small fraction of the whole. A water may contain much organic matter, and be nearly, if not quite, colourless, or it may contain but little, and be deeply tinted. Thus, as mentioned by the author, a sample of water which had been in contact with precipitated alumina was, when examined by the speaker, of the very light blue-green tint of *pure* water when seen in a two-foot tube, although it yielded by combustion 0.160 per 100,000 of organic carbon, and another sample which had been in contact with mine mud was, when clarified by subsidence, colourless in a quart decanter, although 100,000 parts of it yielded on combustion no less than 0.544 part of organic carbon. The author, however, said "The peculiar tint of the water is an indication of the kind of organic matter, and the tint-depth is an indication of the quantity of organic matter in the water." The speaker was not aware of the grounds upon which this statement was made. It was not impossible that spectroscopic examination might help us. The absorption-bands of brown urine and of peat might be different, and it was surprising that the author, who evidently attached so much value to the colour test, had not pushed his investigation in this direction. For his own part he had been unable, except in waters from the same district, to guess the approximate portion of peat from the tint-depth of the water. The tinctorial power of the peat in one district seemed to differ from that in another. But it was scarcely necessary to pursue the subject further, as the author himself concludes his advocacy of the 2-ft. tube by virtually condemning it as a quantitative instrument. The quart decanter, or rather flask, was, in the speaker's opinion, more useful than the 2-ft. tube, because if water appears coloured or turbid in such a vessel the consumer would have just cause of complaint, but not otherwise. He cordially agreed with the author's strictures on superficial and rapid analyses of waters, in which the determinations were "chosen with far greater regard to the analyst's time than to the needs of the inquiry." The so-called partial analyses were often very partial, and often brought disgrace upon the profession of chemistry. It was satisfactory to know that the author not only preached but practised this doctrine; the fulness and minuteness of his analyses were well worthy the attention and imitation of chemists. He also agreed with Dr. Tidy in deprecating a hard and fast division of waters into classes, although a suggestive classification was often useful. He would prefer to modify somewhat the division into four classes adopted by the author, making a separate and more liberal scale for upland surface water, which rarely contained anything hurtful, and a somewhat stricter one for spring, well, and river water, the organic matter in which was very liable to come from dangerous sources. He would therefore propose the following classification:—

SECTION I.—UPLAND SURFACE WATER.

Class I.—*Water of Great Organic Purity*.—Containing a proportion of organic carbon not exceeding 0.2 part in 100,000.

Class II.—*Water of Medium Purity*.—Containing from 0.2 to 0.4 part of organic carbon in 100,000.

Class III.—*Water of Doubtful Purity*.—Containing from 0.4 to 0.6 part of organic carbon in 100,000.

Class IV.—*Impure Water*.—Containing upwards of 0.6 part of organic carbon in 100,000.

SECTION II.—WATER OTHER THAN UPLAND SURFACE.

Class I.—*Water of Great Organic Purity*.—Containing a proportion of organic carbon not exceeding 0.1 part in 100,000.

Class II.—*Water of Medium Purity*.—Containing from 0.1 to 0.2 part of organic carbon in 100,000.

Class III.—*Water of Doubtful Purity*.—Containing from 0.2 to 0.4 part of organic carbon in 100,000.

Class IV.—*Impure Water*.—Containing upwards of 0.4 part of organic carbon per 100,000.

He could not admit, however, without further data the translation of these numbers into terms of oxygen consumed. He had studied this translation for several years in connection with the London waters, and had plotted comparative curves from month to month like those exhibited by Dr. Tidy; and his pupil, Mr. Woodland Toms, had also extended the comparison to other classes of waters. From a large number of these results he selected the following to illustrate the difficulties yet to be overcome before a trustworthy translation of oxygen consumed into organic carbon could be made. In the following tables the column headed "Oxygen" contained the amount of oxygen consumed by 100,000 parts of each water, whilst that headed " $\frac{C}{O}$ " gave the multiplier, by which the oxygen consumed was converted into the organic carbon actually found by combustion of the water residue. The amount of carbon thus found was given in the last column, headed "Org. C."

I. London River Water.

Thames.	Oxygen.	$\frac{C}{O}$	Org. C.
Lambeth	0.164	$\times 1.65$	= 0.271
Grand Junction	0.130	$\times 1.65$	= 0.216
Southwark	0.179	$\times 1.64$	= 0.295
Lea.			
New River	0.067	$\times 1.55$	= 0.104
East London	0.079	$\times 1.85$	= 0.146

In these waters the translation is easy; in fact the three Thames waters require practically the same multiplier, and even if this multiplier were applied to the oxygen consumed by the East London Company's water it would not lead to very serious error. Hence the striking agreement in the comparative curves. The case is very different, however, with other classes of waters, and the multiplier has to be greatly altered, as, for instance, in the following tables:—

II. Well-Waters.

Deep Wells.	Oxygen.	$\frac{C}{O}$	Org. C.
Kent Co.'s	0.015	$\times 5.10$	= 0.077
Colne Valley Co.'s ..	0.0135	$\times 6.90$	= 0.094
Hucknall Tokard ..	0.103	$\times 3.60$	= 0.372
Shallow Well.			
Honiton	0.179	$\times 1.80$	= 0.317
Sutton	0.028	$\times 4.00$	= 0.117

III. Sewage.

Lyme Brook + Sewage	0.452	$\times 5.58$	= 2.527
Effluent water from Crewe Sewage Works	0.245	$\times 4.50$	= 1.104

Here the multipliers not only differ for the most part widely from that of Thames water, but what is much more to be regretted they differ enormously amongst themselves. The gross blunders which might be made by using the oxygen instead of the combustion process are, however, most strikingly illustrated by the following table of contrasts, in which each of two pairs of samples requiring approximately the same amount of oxygen are shown to contain enormously different proportions of organic carbon, and require therefore very different multipliers:—

IV. Contrasts.

	Oxygen.	$\frac{C}{O}$	Org. C.
{ The River Marchnant	0.237	$\times 0.57$	= 0.136
{ Crewe Sewage Effluent	0.245	$\times 4.50$	= 1.104
{ Stream at Hinckley..	0.147	$\times 2.96$	= 0.435
{ River Vyrnwy	0.152	$\times 0.89$	= 0.139

But the most hopeless cases are presented in the following table, in which the results yielded by samples taken from the same upland rivers at different dates are contrasted:—

V. Same Rivers at Different Dates.

	Oxygen.	$\frac{C}{O}$	Org. C.
The Vyrnwy, Sep. 4..	0.422	$\times 0.338$	= 0.148
" " " 30..	0.259	$\times 1.03$	= 0.267
" " Dec. 16..	0.041	$\times 2.92$	= 0.120
The Marchnant, Sep. 4	0.286	$\times 0.55$	= 0.156
" " Oct. 10	0.164	$\times 1.46$	= 0.240

The speaker feared that the utmost attainable in this direction would be a translation of oxygen consumed into organic carbon by the use of a separate factor for each description of water. In the meantime, however, the 1418 cases of approximate coincidence out of 1686 mentioned by the author were very encouraging; and to all chemists who shirk the labour of combustion he strongly recommended the oxygen process interpreted by Dr. Tidy as one far superior to any other, and one which, although rough and ready, would probably only rarely lead them far astray. But in all cases of moment and importance, where the health of large communities was at stake, reliance ought never to be placed upon a method which deals only with the carbon and hydrogen of the organic matter and leaves the nitrogen unnoticed. In conclusion, he congratulated the author on his valuable addition to the literature of water analysis, and on the clearness with which he had brought a great array of facts before the Society. His comparative tables were of great value, and he trusted they would be carefully studied by all chemists who practise water analysis. They formed a chart upon which the rocks so fatal to many a water analysis were so clearly shown that he who runs might read.

At the conclusion of Dr. Frankland's address a general wish was expressed to hear Mr. WANKLYN, who made the following remarks. Unfortunately, he was not able to take so favourable a view of the paper as Dr. Frankland. He would restrict himself to the subject of the paper, and hardly say anything about the paper itself. He believed that he was not bound to notice the paper, and should therefore deal with the subject of it. One of the subjects was the controversy between Dr. Frankland and himself, which commenced in 1867 in the pages of a journal no longer published—*The Laboratory*—and as long ago as that date Chapman, Smith and himself directed attention to the cardinal defect of the combustion process, and this defect had never been overcome. It is this, that the organic matter in the water does not survive the evaporation to dryness. This may be doubted; but let us consider what is the organic matter. We have modified cellulose which is very sensitive to the action of dilute acids; e.g., in a few seconds a solution of cane-sugar, when treated with dilute sulphuric acid, becomes converted into grape-sugar, so as to reduce the copper test, once we get cellulose into the plastic condition it does not need oxidation to break it up. If the organic matter of the residue is not that of the water, it is plain that the process is not valid, and this consideration and the practical difficulty of the process have prevented Mr. Wanklyn from making many water analyses by the combustion method. Dr. Frankland said that he would be content if he had a process to burn up the organic matter in the water itself. Messrs. Cooper and Wanklyn have invented such a process, and have burned up substances in solution. The results obtained are interesting. The actual organic matter present in the London Companies' waters does not exceed 2½ milligrams per litre. Dr. Frankland has found 3.99 milligrams per litre as a mean of many experiments: in his paper, the quantity really does not exceed 2½. After this discrepancy comment on the process is needless.

Mr. KINGZETT said that with regard to the occlusion of nitrogen by copper, Thudichum and himself had shown that copper prepared from the nitrate is quite free from nitrogen. Prof. Tidy's experiments on page 78 proved that permanganate practically did not act on gelatin. As

albuminoids were admitted to be dangerous by all, this fact was a stumbling-block in the use of the process, as it overlooked albuminoids.

Prof. BISCHOF said that Dr. FRANKLAND's reply had been so exhaustive that he would confine himself to a few remarks. Though all agreed that it would be preferable to estimate the organic matter in the water, yet we must recollect that by evaporating the water the organic matter was concentrated, and so could be estimated with even more accuracy than in the water itself. He asked Prof. Tidy whether he had made any experiments by condensing the vapour given off, during the evaporation of water for analysis, which proved that a loss of organic matter had taken place, so as to be able to say the oxygen process has detected so much volatile organic matter in the distillate? His plan of evaporating water prevented to a great extent the destruction of organic matter, because it avoided the frequent alternate exposures to hot water and air. Could Prof. Tidy detect by the oxygen process any difference between milk infected, say, with typhoid and scarlet fever and the same milk not so infected? He would like to know the precise meaning attached by Prof. Tidy, in his reports of the London waters, to the words "efficiently filtered." Also, why Prof. Tidy continues to use the ammonia method in his reports to the Medical Officers of Health when he has admitted that the results of that method are unsatisfactory. In conclusion, he would submit to the President the figures obtained by Prof. Tidy and Dr. Whitmore, both using the albuminoid ammonia method, in their analyses of the West Middlesex and Grand Junction waters, figures which differed by nearly 100 per cent, and asked if Mr. Wanklyn or anyone else could account for this discrepancy.

Mr. WANKLYN remarked that he had never had any difficulty in obtaining his alkaline permanganate free from ammonia, and could not tell what results might be arrived at by using impure solutions of permanganate, and, allowing for the impurity: it was also very important that chemists should be trained in a correct manner.

Dr. VOELCKER said that an impartial observer would come to the conclusion that all methods were more or less defective, and some gave very erroneous results. He would most earnestly urge the importance of determining all the constituents of a water, organic and inorganic, and not founding our opinion on one factor.

Mr. GROSJEAN said that all must have recognised the great advantage of having a paper printed before it was discussed, and trusted that it would form a precedent and ultimately the rule. Prof. Tidy did not seem to have standardised his permanganate, but had apparently assumed it to be pure. It was usually standardised, and hence probably the origin of the multiplication of the oxygen used by 8, as the equivalent of oxygen $\times 8$ equals nearly the equivalent of oxalic acid. The commencement of the action of permanganate on oxalic acid is characterised by a tardiness which was explained by Vernon Harcourt, *Chem. Soc. Journ.*, 1867.

Dr. DUPRE protested against the assumption that a chemist who used the albuminoid ammonia process did so to shirk the trouble of the combustion process; and, moreover, did not see why the time, expense, and trouble of a process should not have a certain weight. He had used both the ammonia and permanganate processes, and found the results fairly concordant, with, however, strange exceptions now and then. He had not had any difficulty in preparing alkaline permanganate solution free from ammonia. He gave as an instance of concordant results obtained by the ammonia process, the results obtained by six chemists in examining 249 waters:—Of these, 66 were first class waters, and all agreed that 64 were first class waters and 2 second class; 60 were second class waters, and all agreed that 53 were second class, 6 first class, 1 third; 123 were cistern waters, and 6 were put in the first class, 81 in the second, and 36 in the third.

Mr. W. THORP asked Prof. Tidy what his conception was as to the nature of the organic impurity, as he had

compared it to hydrocyanic acid, &c. He did not think that any free sulphuric acid was likely to be formed during the evaporation, as the carbonates present would be more than sufficient to neutralise any that might be formed, and if there was any chance of such an occurrence it might be avoided by the addition of a little pure sulphite of sodium. He did not think that Prof. Tidy had done justice to Nesslerising. When in work his (Mr. Thorp's) error in estimating tints was only 3 per cent. Railway men were not accustomed to judge minute differences, and so their arrangement of Nessler tints was by no means a fair experiment. He thought great difficulty would be experienced in applying the oxygen process to waters containing nitrites. Moreover, some waters containing no nitrites rapidly reduced permanganate. He did not place much reliance on the colour of a water.

Dr. HAKE remarked that when copper was cooled in CO_2 no occlusion took place.

Prof. TIDY thanked the Fellows for the kind manner in which they had received his paper, and expressed his satisfaction at having provoked such an interesting discussion. He had concluded that the poison in water was volatile from analogy, because when it did act it was very virulent, and virulency and volatility usually go together. He relied on the colour of a water more as a useful adjunct to the results obtained by analysis. In the Thames water the oxygen used $\times 8$ gives the difference very nearly between the inorganic salts and the total residue.

The warmest thanks of a crowded meeting were carried by acclamation and tendered to Prof. Tidy for his paper.

The Society then adjourned to February 20, when the following papers will be read:—"Investigations into the Action of Substances in the Nascent and Occluded Conditions (Hydrogen, continued)," by Dr. Gladstone and Mr. Tribe; "On some Methods of Vapour-Density Determination," by J. V. Brown; "On the Quantitative Blowpipe Assay of Mercury," by G. Attwood.

PHYSICAL SOCIETY.

Annual Meeting, February 8, 1879.

Prof. W. G. ADAMS, President, in the Chair.

THE PRESIDENT read the report of the Council, which showed that the papers had been more numerous during the past than in any previous year, and that their value and interest had been well sustained. A copy of the collected papers of the late Sir Charles Wheatstone was laid on the table, and the work will shortly be issued to the members of the Society. The President then gave a brief review of the physical work of the past year, dwelling more especially on the papers read at the meetings.

Votes of thanks were then passed to the President, to the Lords of the Committee of Council on Education, to the Demonstrator, Treasurer, Secretary, and Auditors, and the following were elected as Council and Officers for the ensuing year:—

President—Prof. W. G. Adams.

Vice-Presidents—Prof. G. C. Foster, Prof. R. B. Clifton, Lord Rayleigh, Dr. Spottiswoode, Sir W. Thomson.

Secretaries—Prof. A. W. Reinold and Mr. W. Chandler Roberts.

Treasurer—Dr. E. Atkinson.

Demonstrator—Prof. F. Guthrie.

Other Members of Council—Capt. W. de W. Abney, Dr. Warren de la Rue, Major E. R. Festing, Prof. Fuller, D. Huggins, Prof. A. B. W. Kennedy, Prof. McLeod, The Earl of Rosse, Mr. G. Johnstone Stoney, Dr. Wormell.

Honorary Members—Prof. G. R. Kirchhoff, Dr. J. Plateau.

The meeting was then resolved into an ordinary one, and Dr. O. J. LODGE read a short paper on a method of calculating the curve of temperature in a rod along which heat is being conducted.

Mr. SHOOLBRED gave an account of electric lighting, illustrated by diagrams of the most recent magneto- and dynamo-electric machines and examples of the lamps in vogue. The only surviving magneto-machine is that of De Meriten's, which is incomparably superior to the older ones of Nollet and Holmes. The dynamo-electric machines described were the continuous-current machines of Siemens, Gramme, Wallace-Farmer, and the alternating-current machines of Wilde, Gramme, and Lontin. Wilde's machine is the first of these, or parent machine, and Lontin's so resembles it that the latter cannot be used in England. In these machines the current from a continuous machine is passed through a second machine, which yields the alternating currents. In Lontin's machine, also, a number of distinct currents are generated in separate circuits, each of which is capable of feeding several lights. There is now one in use on the Western Railway of France which gives three distinct currents, each of which supplies four different lamps, making a total of twelve lights. The American Brush machine was also mentioned. The Dubosq lamp, which was the first regulator, is well adapted for laboratory purposes, but for practical purposes the Serrin is preferable. Rapiéff's lamp is used in the *Times* office. The De Mersanne, which was highly spoken of at the Paris Exhibition, moves the carbons by bevelled gearings. The Wallace-Farmer lamp, though durable, is unsteady, perhaps because only inferior gas carbon has yet been used. Jablochkoff's candle was found to be defective from the solid insulator, such as plaster, used between the carbon. This made it very expensive also. Experiments in Paris had shown that whereas Jablochkoff's system cost 10d. per hour per light, the other systems cost only one half of that. In Wilde's candle the solid insulator was dispensed with, air taking its place, the arc always tending to keep at the top of the candle by electro-dynamic repulsion. In the De Meriten's candle three strips of carbon were used, the intermediate one being a stepping-stone to the arc which passes between the two outer ones. Werdermann's and Reynier's so-called incandescent lamps were also shown. Mr. Shoolbred, after alluding to the fact that the upper (positive) carbon takes a crater form, and hence becomes a reflector shedding the light downwards, stated that experiments had proved the line of maximum intensity of light to pass downward at an angle of 60° to the axis of the vertical carbons. By giving the positive carbon a horizontal displacement behind the lower negative one, Mr. Douglas, of the Trinity House, had been able to raise this line till it became horizontal, an advantage in light-houses. He also pointed out that, whereas in Paris the

Jablochkoff waxed for a period short compared to that in which it waned, in London it waxed for longer than it waned, which was of course an improvement; and Mr. Shoolbred suggested that it might be due to the fact that the engine worked at a speed nearer to that of the machine, and that the machine was founded more solidly in London than in Paris.

Mr. WERDERMAN said that it was a mistake to call his lamp an incandescent one, the fact being that all carbon lamps gave light from the incandescence of the positive carbon, and that a small arc was formed in his lamp between the two electrodes, which could be varied by the pressure between them. He maintained that it was as easy to produce 500 lights as 10 from the electric light by sub-division, as he hoped soon to show, and stated that the size of the carbons greatly controlled the intensity of the light.

Prof. AYRTON held that the obstacle to the sub-division of the electric light was not an electrical one, but was due to the fact that the amount of light produced by the current is not in direct proportion to the amount of the heat produced.

In contradiction to Prof. Ayrton, Mr. WERDERMAN stated that in the electric arc the opposing electromotive force was proportional to the original electromotive force.

Prof. SYLVANUS P. THOMSON pointed out that residual magnetism in the cores of the bobbins of dynamo-electric machines lowered their efficiency, and hence short cores, as in the Wallace-Farmer machine, were an improvement.

EDINBURGH UNIVERSITY CHEMICAL SOCIETY

January 29, 1879.

ALEXANDER MACFARLANE, D.Sc., F.R.S.E., in the Chair.

A PAPER was read by Mr. J. S. THOMSON, on "*Paraffin and what is got from it, as illustrated by Exhibits at the Paris Exhibition of 1878.*" A full account was given of the modes of preparation of these exhibits, which consisted of specimens of all the commercial products of the Addiewell Chemical Works. These included naphtha, burning oils, lubricating oils, solid paraffin in blocks (weighing not less than 7 cwts. each), sulphate of ammonia, and candles of various kinds made from the paraffin wax. The methods of preparation of other products of paraffin were also explained; of normal paraffins, alkaline bases of the leucoline series found in the acid tars, phenols and analogous bodies found in the soda tars, chrysin and paraffins of various melting-points, from 21° to 65.5° C.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATER.

JANUARY, 1879.

THE following are the returns of the Society of Medical Officers of Health:—

	Appearance in 2 foot Tube.	Ammonia.		Nitrogen as Nitrate, &c.	Oxygen used to Oxidise Organic Matter.	Total Solids.	Lime.	Magnesia.	Chlorine.	Sulphuric Anhydride.	Hardness on Clark's Scale.	
		Saline.	Organic.								Before Boiling.	After Boiling.
		Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Degs.	Degs.
<i>Thames Water Companies.</i>												
Grand Junction	Slightly turbid	0.000	0.012	0.165	0.130	21.40	9.230	0.720	0.72	1.600	13.2	5.10

The quantities of the several constituents are stated in grains per imperial gallon.

NOTE.—The amount of oxygen required to oxidise the organic matter, nitrites, &c., is determined by a standard solution of permanganate of potash acting for three hours.

C. MEYMOTT TIDY, M.B.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 3, January 20, 1879.

Observations on M. Pasteur's Second Reply.—M. Berthelot.—The author points out that M. Pasteur, though declaring beer to be anærobian, admits that this supposition has not been demonstrated.

Reply to the Notes of M. Trécul of Dec. 30 and Jan. 13.—M. Pasteur.—A continuation of the controversy on anærobian and anærobian organisms.

Temporary Magnetic Powers Developed by Influence in Certain Specimens of Nickel and Cobalt as Compared with Iron.—Henri Becquerel.—Bars of nickel become saturated more rapidly than bars of iron, and consequently setting out from a certain intensity a bar of nickel becomes a temporary magnet almost constant, while iron becomes magnetised more for growing intensities. The difference between the magnetic properties of bars of iron and nickel are so much the more considerable as the conditions of magnetic are nearer to those which determine saturation in one or the other.

Classification of Colours and the Means of Reproducing Coloured Appearances by Three Special Photographic Proofs.—C. Gros.—The author distinguishes two categories comprised under the word colours: lights and pigments. The elementary lights which by their mixture produce all kinds of shades are the green, violet, and orange rays. The elementary pigments which by their mixture produce all kinds of shades are red, yellow, and blue. To obtain directly the elementary tints of rays and of pigments it is sufficient to look through a prism at a white stripe upon a black ground, and at a black stripe upon a white ground. In the first case we see an orange, green, and violet spectrum, and in the latter case a blue, red, and yellow spectrum. In the former case the orange, green, and violet are elementary rays, and in the latter the red, blue, and yellow are rays combined two and two. The author then exhibits and describes an apparatus, which he names the chromometer, and by means of which he produces the protographic effect above mentioned.

Researches on the Effects of Induction Across Telephonic Circuits by Means of the Microphone and the Telephone.—D. Hughes.—Taken from an English source.

New Voltaic Element with a Constant Current.—A. Héraud.—The author uses as an exciting liquid hydrochlorate of ammonia; the depolarising body is mercurous chloride. When the circuit is closed the hydrochlorate of ammonia in presence of zinc gives zinc chloride, forming ammonia and hydrogen, which two bodies go to the positive electrode. The hydrogen reduces the mercurous chloride, producing metallic mercury, hydrochloric acid, and consequently hydrochlorate of ammonia. As long as there exists mercurous chloride around the positive electrode, hydrochlorate of ammonia will be regenerated.

Tetric Acid and its Homologues.—Eug. Demargay.—An account of the tetric, pentic, hexic, isohexic, and heptic acids. These acids agree very closely in their chemical properties, and are coloured a violet-red by ferrous chloride.

Reimann's Fürber Zeitung,
No. 47, 1878.

Dr. Lunge confirms the statements of Miller on the use of tropeolin OO for the titration of soda, for deter-

mining the free acid in sulphate of alumina, &c. So long as no free acid is present the yellow colouring-matter remains unchanged. If there is the smallest excess of hydrochloric acid the colour turns first to magenta, then to orange, and after a few seconds disappears entirely. The author has tested a number of the azo colouring-matters, and has found that they are all indifferent to free carbonic acid, and are capable of marked changes of colour in presence of the slightest excess of mineral acid, or inversely. These changes are most beautifully shown by Poirrier's Orange III. (dimethyl-anilin-diazosulphobenzolic acid), by diazo- α -sulpho-naphthyllic acid, and amido-benzol. Tropeolin OOO is suitable for the detection of alkali (caustic or carbonated), as it undergoes the opposite change of colour from tropeolin OO, being yellow in an acid solution and magenta-red in alkaline liquids. Weaker acids—such as the sulphurous, oxalic, &c.—produce less distinctly marked changes of colour. Acetic acid, like the carbonic, is indifferent to the azo-compounds. Hyposulphite of soda behaves exactly like the salts of strong mineral acid. With the aid of these indicators soda-ash, &c., may be titrated in the cold.

Les Mondes, Revue Hebdomadaire des Sciences.
No. 16, December 19, 1878.

This issue contains no original chemical matter.

No. 17, December 26, 1878.

The only original chemical matter in this issue is a description of the celebrated aniline-colour works of A. Poirrier, at St. Denis, and of the dyes which have been either invented or at least manufactured there. The writer enumerates as such—Violet (produced with potassium bichromate); dimethyl-anilin violet, otherwise known as Paris violet; benzylated dimethyl-anilin violet, purer in tone than Paris violet, and capable of being applied upon wool in presence of acids; methyl-anilin green, formed by acting upon the violet with methyl-chloride; dibenzyl-anilin green, which has not proved commercially successful by reason of its very sparing solubility; phenylen-diamin brown and chrysoidin; cachou de Laval, otherwise known as the patent colours of Croissant and Bretonnière, formed by the action of sodium sulphide upon organic matter. (This colour does not seem to possess any distinctive novelty, and, though exceedingly fast, yields dull shades.) Mention is next made of the oranges and rocellin. The last of these colours is obtained by the reaction of the diazoic derivative of sulpho-conjugated naphthylamin upon naphthol B; the shade produced is very like that of orchil, but brighter, faster, and more economical.

Nos. 1 and 2, January 2 and 9, 1879.

These issues contain no original chemical matter.

Revue Universelle des Mines, de la Metallurgie, &c.,
Tome 4, No. 2, September and October, 1878.

The only chemical paper here is a note by Prof. J. B. Caldwell on the determination of phosphorus in ores of iron, and in cast-iron and steel, taken from the *New York Metallurgical Review*.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin,
No. 14, 1879.

Transformation of Dibromethylen into a Keton with Four Atoms of Carbon by Means of Hypobromous Acid.—E. Demole.—The author considers it as established that on the oxidation of dibromethylen there is really formed a transition compound, bromacetylen, in the nascent state. At low temperatures this compound

becomes polymerised, resuming HBr, whilst at higher temperatures it takes up simultaneously oxygen and hydrobromic acid, and is converted into bromacetyl-bromide.

Separation of Zinc and Nickel.—F. Beilstein.—The sufficiently diluted solution of the nitrates or sulphates is mixed with ammonia till an alkaline reaction is obtained, and then acidified with pure citric acid. When the solution is perfectly cold sulphuretted hydrogen is introduced till the liquid has a distinct smell, which is generally effected in five to ten minutes. If much zinc is present sulphuretted hydrogen is introduced for five minutes at a time, letting the liquid stand after each introduction, and repeating this till the smell of the gas does not disappear on standing. In this manner we avoid a needlessly long treatment with sulphuretted hydrogen by which traces of nickel sulphide may be carried down. The precipitate of zinc sulphide is allowed to stand for twenty-four hours in the cold, and is then weighed as such. The filtrate is evaporated to a small volume, and after supersaturation with ammonia the nickel is thrown down electrolytically, in which operation care must be taken that no sal-ammoniac is present, as it hinders the precipitation of nickel. The solution should be a nitrate.

On β -Chlorocymol from Thymol.—E. v. Geichten.—A hypothetical and controversial paper, not susceptible of useful abstraction.

Certain Fluorine Compounds of Vanadium.—H. Baker.—A valuable and detailed account of the formation and properties of the fluoxy-vanadates of potassium, ammonium, and zinc, and of fluoxy-hypo-vanadate of ammonium.

Certain New Derivatives of Benzoic Acid.—P. Griess.—The author describes ϵ -nitramido-benzoic acid, ϵ -oxy-nitro-benzoic acid, α -oxy-nitro-benzoic acid, and γ -oxy-nitro-benzoic acid.

Halogen Substitution-products of Ethan and Ethylen (Eleventh Communication).—W. Stædel.—An account of the hexa-chloride of carbon and of the somewhat numerous chlorobromo- and bromo-substitution products of ethan and ethylen.

Compounds of Organic Bases with Mercuric Chloride.—Otto Klein.—In this memoir the author describes certain mercuric compounds of dimethyl-anilin.

On Isoindol (Thirteenth Communication).—W. Stædel and M. Kleinschmidt.—Isoindol presents one of the most interesting cases of pleochroism. If a columnar crystal is held to the light and slowly turned on its axis it appears in succession green, yellow, deep red, blue, and indigo-blue.

Dinitro-benzo-phenon and Dioxy-benzo-phenon.—W. Stædel and E. Sauer.—Dinitro-benzo-phenon is most readily obtained by the oxidation of dinitro-diphenyl-methan. Dioxy-benzo-phenon is best prepared from the hydrochlorate of diamido-benzo-phenon.

Brom-nitro- and Brom-amido-anisols.—W. Stædel and G. Damm.—Not suitable for abstraction.

On Uvic Acid.—W. Stædel.—During an attempt to resolve synthetic uvic acid into dextro- and lævo-tartaric acid a solution of the neutral sodium-ammonium salt was prepared. From this solution there were at first deposited large well-developed crystals of the monoclinic system, on which there were no hemihedral surfaces, and whose solution was optically inactive. In the mother-liquor of these crystals there appeared the rhombic crystals of the two sodium-ammonium tartrates, with their usual hemihedral surfaces.

On Diphenyl Bases.—H. Schmidt and G. Schultz.—The authors have undertaken a complete examination of all the known amido-compounds of diphenyl.

Supplementary Remarks on Alstonia Constricta.—O. Hesse.—The author, in the former paper, questioned the presence of quinin in Alstonia bark. He now learns

that Baron Muller, of Melbourne, who discovered the species, also denies that it contains quinin.

On Diphenyl Benzols.—H. Schmidt and G. Schultz.—The authors seek to ascertain the relation—if any—of violanilin to diphenyl-benzol.

Amidins and Thiamids of Mono-basic Organic Acids.—A. Bernthsen and H. Trompeter.—The authors give an account of ethenyl-tolyl-amidin, benzenyl-naphthyl-amidin, ethenyl-naphthyl-amidin and certain of its salts, benzo-thio-toluidid, aceto-thio-toluidid, benzo-naphthyl-thiamid, aceto-naphthyl-thiamid, benzamido-tolyl-thiamid, benzyl-anilin, and ethyl-naphthyl-amin.

Certain Double Salts of Bivalent Iridium.—C. Seubert.—An examination of the iridic double salts of sodic bisulphite.

Atomic Weight of Iridium.—C. Seubert.—The author's determinations give as a mean result 192.744 ($H = 1$). He points out that Berzelius admits the presence of osmium in the iridium which he employed.

On Absorption Spectra.—J. Landauer.—A spectroscopic examination of safranin. The author not merely agrees with Vogel in doubting the universal applicability of the proposition that every chemical compound has its specific spectrum, but concludes that absorption spectra throw light upon the constituents of a compound only in so far as the colour of a body can be regarded as characteristic of its chemical composition. For the accurate determination of colours the spectroscope is as serviceable as is the microscope for the determination of forms.

Action of Dry Gaseous Hydrochloric Acid upon Sulphates.—C. Hensgen.—In this memoir the author describes the action of dry hydrochloric acid gas upon ferrous sulphate. At elevated temperatures the anhydrous salt is decomposed, and pure anhydrous ferric chloride is formed. From the hepta-hydrated salt was obtained $Fe_2Cl_6 \cdot 2H_2O$ in green acicular crystals, and $FeSO_4 \cdot 6H_2O$ in tabular plates.

MISCELLANEOUS.

Royal Commission.—The Queen has approved the appointment of Mr. Warrington W. Smyth, F.R.S., Sir George Elliot, M.P., Mr. F. A. Abel, C.B., Mr. Thomas Burt, M.P., Mr. Robert Bellamy Clifton, F.R.S., Prof. Tyndall, F.R.S., Mr. Lindsay Wood, and Mr. William Thomas Lewis, as Her Majesty's Commissioners for the purpose of inquiring and reporting whether, with respect to the influence of fluctuations of atmospheric pressure upon the issue of fire-damp from coal, to the adoption and efficient application of trustworthy indicators of the presence of fire-damp, and generally to systematic observation of the air in mines, to improved methods of ventilation and illumination, to the employment of explosive agents in the getting of minerals, and to other particulars relating to mines and mining operations, the resources of science furnish any practicable expedients that are not now in use and are calculated to prevent the occurrence of accidents or limit their disastrous consequences.—*Times*.

Moist Water Colours for Students.—Lech tier Barbe, and Co. have issued a set of student's moist water colours in tin pans. These moist colours are said to be pure, unadulterated pigments. The use of water colours in the moist state, with artists, has almost superseded that of dry cake colours. The latter may have a superiority in some instances, yet the moist, affording a supply of colour with more freedom and rapidity, have come to be generally preferred, and the only obstacle to their being more extensively used still has hitherto been their high price. The shilling box contains the ten colours and three brushes as recommended by the Society of Arts. The main and novel feature of the box is that the colours are

contained in small tin pans; that these pans are removable, and that, when used up, any of them can be replaced by another one, just as in artists' colour boxes. Thirty of the most useful moist colours are manufactured and sold in those small tin pans; so that additional colours may be put in the box, in order to bring it fully within any object in view in water-colour drawing.

MEETINGS FOR THE WEEK.

- MONDAY, 17th.**—Medical, 8.30.
London Institution, 5.
Society of Arts, 8. "Dwelling Houses: Their Sanitary Construction and Arrangements," by Dr. W. H. Corfield, M.A. (Cantor Lectures)
- TUESDAY, 18th.**—Civil Engineers, 8.
Royal Institution, 3. "Animal Development," Prof. Schäfer.
Zoological 8.30.
- WEDNESDAY, 19th.**—Society of Arts, 8. "Turkish Resources and their Ready Development," by J. L. Haddan.
Meteorological, 7.
Society of Public Analysts, 8. "On the Influence of the Decomposition in Butters from Age on the Specific Gravity of the Fat and the Percentage of Soluble and Insoluble Acids," by E. W. T. Jones, F.C.S. "Notes on the Analysis of Butter," by J. M. Milne, M.D. "On Condensed Milk," by O. Hehner, F.O.S. "On Analysis of Coffee Leaves," by O. Hehner, F.C.S. "On the Falsification of Milk," by C. A. Cameron, M.D.
- THURSDAY, 20th.**—Royal, 8.30.
Royal Institution, 3. "Sound," Prof. Tyndall.
Royal Society Club, 6.30.
Chemical, 8. "Investigations into the Action of Substances in the Nascent and Occluded Conditions: Hydrogen (continued), by Dr. Gladstone and Mr. Tribe. "On some Methods of Vapour Density Determination," J. T. Brown. "On the Quantitative Blowpipe Assay of Mercury," by G. Attwood.

MR. COX, VALUER OF CHEMICAL PLANT, offers his services on the usual terms. Twenty years' experience. Estimates for all description of plant, plans, &c.—Glenmohr House, New Charlton London, S.

420 pp., Royal 32mo., French morocco, gilt edges, price 3s.

A POCKET-BOOK FOR CHEMISTS,
A CHEMICAL MANUFACTURERS, METALLURGISTS, DYERS, DISTILLERS, BREWERS, SUGAR-REFINERS, PHOTOGRAPHERS, STUDENTS, &c., &c. By THOMAS BAYLEY, Assoc. R.C. Sc. Ireland, Analytical and Consulting Chemist, Demonstrator of Practical Chemistry, Analysis, and Assaying, in the Mining School, Bristol.

Synopsis of Contents.

Atomic Weights and Factors—Useful Data—Chemical Calculations—Rules for Indirect Analysis—Weights and Measures—Thermometers and Barometers—Chemical Physics—Boiling-points, &c.—Solubility of Substances—Methods of obtaining Specific Gravity—Conversion of Hydrometers—Strength of Solutions by Specific Gravity—Analysis—Gas Analysis—Water Analysis—Qualitative Analysis and Reactions—Volumetric Analysis—Manipulation—Mineralogy—Assaying—Alcohol—Beer—Sugar—Miscellaneous Technological Matter relating to Potash, Soda, Sulphuric Acid, Chlorine, Tar Products, Petroleum, Milk, Tallow, Photography, Prices, Wages, &c.

London: E. and F. N. SPON, 46, Charing Cross.
New York: 446, Broome Street.

A Young Man (18) wishes to be engaged for three years in the Laboratory of a Chemical Works. Period of instruction two years.—Address, F. W. S., 47, Neshell's Place, Birmingham.

Manager of Tar and Ammonia Distillery will be disengaged on February 10, and will be open for Re-engagement. Advertiser has a good practical knowledge of the business, and is a steady energetic man.—Address No. 60, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Situation wanted by a Competent Analyst as Assis'ant or Principal. Good teacher. Apply, Public Analyst, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, a Situation in Works, Laboratory, Patent Office, or as Teacher of Chemistry and Chemical Technology by a Scientific Chemist of great practical experience, and well up in English, German, and French.—Address, P. 11, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO PAPER MAKERS, CHEMICAL MANUFACTURERS, AND OTHERS.

TO LET, at Low Rentals, Works and Land in Plots of Two to Ten Acres, near Swansea. Coals obtainable from 4s. 6d. per ton. Water good and abundant. Any description of manufactory can be carried on. Excellent Railway, Canal, and Dock accommodation close at hand.—Apply to Richard Hall, Esq., 37, Great George Street, Westminster, or Mr. Thomas Williams, Aberdulae, Neath, Glamorganshire.

The Authors of "A Practical Treatise on the Manufacture of

SULPHURIC ACID,"

with nearly 200 new illustrations (Sampson, Low, and Co., 188, Fleet Street, E.C.) are prepared to furnish plans and advice and superintend the erection of plant in all parts of the world.—Address, L. and L., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

BERNERS COLLEGE of CHEMISTRY.

Instruction and preparation in CHEMISTRY and the EXPERIMENTAL SCIENCES under the direction of Professor E. V GARDNER, F.A.S., M.S.A.

The Class Rooms are open from 11 to 3 a.m. and from 7 to 10 p.m. daily.

Special facilities for persons preparing for Government and other examinations.

Private Pupils will find every convenience.

Analyses, Assays, and Practical Investigations connected with Patents, &c., conducted.

Prospectuses and full particulars on application to Prof. Gardner at Berners College, 44, Berners-street, W.

WILLIAM AND WILLIAM T. FIELD,
MANUFACTURERS of the Celebrated
STAFFORDSHIRE BLUE BRICKS, specially adapted for Chemical Plant, i.e., Acid Towers, &c. Also all other kinds of Best Staffordshire Blue Bricks, Pavings, Plyths, Splays, Copings, &c. &c. Prices and samples on Application.

TESTIMONIAL.

"We have used the Blue Staffordshire Brick for Sulphuric Acid Towers, &c., manufactured by Messrs. Field, for the last fifteen years, during which time they have given great satisfaction. We recommend them to the Chemical Trade, believing there is nothing better in the market."—(Signed) WILLIAM HUNT and SONS, Lea Alkali Works, near Wednesbury, Staffordshire, February, 1878.

Absorption of Gases by Charcoal.

77

ABSORPTION OF GASES BY CHARCOAL.

PART II.

ON A NEW SERIES OF EQUIVALENTS OR MOLECULES.*

By R. ANGUS SMITH, Ph.D., F.R.S.

In the *Transactions of the British Association*, 1878, Norwich, on page 64 of the *Abstracts*, there is a preliminary notice of an investigation into the amount of certain gases absorbed by charcoal. I made the inquiry from a belief previously expressed in a paper of which an abstract is in the *Proceedings of the Royal Society*, page 425, for 1863. I said in that paper that the action of the gas and charcoal was on the border line between physics and chemistry, and that chemical phenomena were an extension of the physical; also that the gases were absorbed by charcoal in whole volumes, the exceptions in the numbers being supposed to be mistakes. The results given were:—

Hydrogen	1.00
Oxygen	7.99
Carbonic oxide	6.03
Carbonic acid	22.05
Marsh-gas	10.01
Nitrous oxide	12.90
Sulphurous acid	36.95
Nitrogen	4.27

It was remarked that the number for nitrogen was probably too low; I had some belief that the charcoal retained a certain amount which I had not been able to estimate.

For common air, the number 40.065 crept into the paper or abstract instead of the quotient 7.06

I considered the numbers very remarkable, but was afraid that they would be of little interest unless they could be brought more easily under the eyes of others; my experiments were somewhat laborious; the exact numbers were seldom approached by the single analysis, but were wholly the result of a series of irregular averages and apparently irregular experiments. The cause of this was clear, as I believed, namely, the irregular character of the charcoal with which I had to deal. The experiments were forgotten, I suppose, by most men, but the late Prof. Graham told me that he had repeated them with the same results that I had published. I might have considered this sufficient, but waited for time to make a still more elaborate investigation of the subject, and to take special care with oxygen, in the belief that, the rule being found, the rest of the inquiry would be easy; this was extended to nitrogen, but not by so many experiments as with oxygen. I am now assured of a sound foundation for inquiries, which must take their beginning from the results here given.

It is found that charcoal absorbs gases in definite volumes, the physical action resembling the chemical.

Calling the volume of hydrogen absorbed 1, the volume of oxygen absorbed is 8. That is, whilst hydrogen unites with eight times its weight of oxygen to constitute water, charcoal absorbs eight times more oxygen by volume than it absorbs hydrogen. No relation by volume has been hitherto found the same as the relation by weight.

The specific gravity of oxygen being 16 times greater than hydrogen, charcoal absorbs 8 times 16, or 128 times more oxygen by weight than it does hydrogen. This is equal to the specific gravity of oxygen squared and

divided by two $\frac{16^2}{2}$, or it is the atomic weight and specific gravity multiplied into each other, 16×16 , and divided by two $\frac{256}{2} = 128$.

Nitrogen was expected to act in a similar way, but it refused. The average number of the latest inquiry is 4.52, but the difficulty of removing all the nitrogen from charcoal is great, and I suppose the correct number to be 4.66. Taking this one as the weight absorbed, $14 \times 4.66 = 65.3$, or it is $\frac{14^2}{3}$. Oxygen is a dyad; nitrogen a triad.

We have then carbonic acid not divided, but simply 22 squared = 484.

Time is required for full speculation, but the chemist must be surprised at the following:—

Carbonic oxide	6	volumes.
Carbonic acid, CO ₂	6+16	" = 22.00
Marsh-gas, CH ₄	6+4	" = 10.00
Protoxide of nitrogen, NO	8+4.66 (N) (4.9)	= 12.66

These four results belong to the early group not corroborated lately, but so remarkably carrying out the principle of volume in this union, giving numbers the same as those of weight in chemical union, that they scarcely require to be delayed.

I am not willing to theorise much on the results; it is here sufficient to make a good beginning. We appear to have the formation of a new series of molecules made by squaring our present chemical atoms, and by certain other divisions peculiar to the gases themselves. Or it may be that the larger molecule exists in the free gas, and chemical combination breaks it up. These new and larger molecules may lead us to the understanding of chemical combinations in organic chemistry and whenever there is union not very firm, and may also modify some of our opinions on atomic weights and the motion of gases.

Of course, I cannot pretend to give the result of these results; but as we have here the building up of a molecule by volumes, so as to form an equivalent of physical combination analogous to the chemical equivalent, it is impossible to avoid seeing that it indicates the possibility of our present equivalents being made up in a similar manner.

I did not expect these numbers; but I certainly, as my previous paper showed, had in full view a necessity for some connexion between physical and chemical phenomena more decided than we possessed.

VOLUMETRIC ESTIMATION OF SUGAR BY AN AMMONIATED CUPRIC TEST GIVING REDUCTION WITHOUT PRECIPITATION.*

By F. W. PAVY, M.D., F.R.S.

To be able to effect the quantitative determination of a body with accuracy and facility is an important matter looked at in relation to the study of its bearings. In the case of sugar there are no reliable means of precipitating and weighing it, either alone or in combination, and thus in the chemical estimation of this principle an indirect method has to be resorted to. The only property upon which dependence can be placed, for the purpose of chemical quantitative analysis, is its reducing action, under the influence of heat, upon certain metallic oxides, and that of copper is the one which general experience shows to answer best.

In the ordinary volumetric application of the copper

* Abstract of a Paper read before the Royal Society Feb. 6, 1878.

* A Paper read at the Royal Society, January 16, 1879

test the precipitation and diffusion of the reduced suboxide through the liquid interferes with the clear perception of the precise point of complete decoloration, and thus detracts from its delicacy. For purposes where minute accuracy is of no moment, a sufficiently approximate result can be obtained, but for physiological investigation, and in other cases where precision is indispensable, the process is quite unfit for employment.

With the view of obtaining increased accuracy, chemists have had recourse to the plan of collecting the precipitate of reduced suboxide and weighing it as such or after reversion into the oxide. From the difficulty, however, that exists in procuring the metallic oxide in a pure and uniform state, and from the impossibility of completely freeing the filter paper used from adhering surplus copper solution, some uncertainty is given to the results obtained by this method. To obviate the difficulty here presented I suggested, in a communication published in the *Proc. Roy. Soc.* for June, 1877, that the precipitated suboxide should be collected and dissolved, and the copper frequently thrown down by the agency of galvanic action upon a platinum cylinder, as is now frequently done in the assaying of copper ores. The process has been found, as shown by the closeness observable in the results of counterpart analyses, to admit of the greatest precision, and I have turned it to extensive account in some recent physiological investigations I have conducted. In its application to such a purpose it may be held that time and labour should be considered as of no moment, but it frequently happens that a more ready process of investigation is needed than the gravimetric supplies, and on this account a volumetric method, free from the objection I have pointed out as belonging to the ordinary plan, constitutes a desideratum.

A few years back Bernard introduced, for physiological purposes, a modification of the ordinary volumetric process, which is attended with reduction and the non-precipitation of the reduced oxide. The process involves the employment of a large quantity of caustic potash, and the presence in the product to be tested of extraneous organic matter. Under these circumstances it happens that the reduced suboxide is held in solution instead of being allowed to fall, and thus decoloration without precipitation occurs and enables the point of disappearance of the colour of the test to be ascertained with precision. Bernard, in his remarks upon the test, simply made mention of the fact that under these conditions reduction without precipitation took place, but Dr. d'Arsonval,† his *Préparateur* at the College of France, refers the effect to the solvent influence of the extraneous organic matter in presence of the alkali.

Whilst engaged upon an enquiry into the merits of this test, the conclusion suggested itself to me that the agency preventing the deposition of the suboxide was the development of ammonia. With an absolutely pure solution of sugar, such as may be obtained by inverting the ordinary crystallised cane sugar (refined loaf sugar) no amount of potash will hinder the instantaneous precipitation of the suboxide. With commercial grape sugar, however, and in a still more marked manner with honey, interference with precipitation is exerted, and this, I am led to conclude, is due to the action of the potash in producing ammonia from the small quantity of nitrogenous organic matter incidentally present.

With this before me, the idea presented itself of resorting to the direct employment of ammonia for attaining the same result. It is well known to chemists that ammonia is a powerful solvent of the suboxide of copper, leading to the production of a perfectly colourless liquid; and this, from the facility with which it absorbs oxygen, quickly assumes a blue colour under exposure to air from the re-conversion of the cuprous into the cupric oxide.

If ammonia be added to the ordinary Fehling's solution, a liquid is obtained which is rendered colourless by boiling

with a sufficiency of sugar to effect the complete reduction of the cupric oxide present to the state of suboxide. As the saccharine product is dropped in the blue colour gradually fades, without any occurrence of precipitation to interfere with the perception of the precise moment when the point of complete decoloration is attained. The ammonia exerts no interference with the process of reduction, but simply dissolves the reduced oxide, leading, when complete decoloration is effected, to the production of a perfectly colourless, limpid liquid.

Enough ammonia must be present to secure that the suboxide is held in solution, and precaution must be taken that whilst the analysis is being performed the reduced oxide does not become re-converted into the oxide by exposure to the air. To obviate this the operation should be conducted in a flask instead of an open capsule.

The appliance that naturally suggests itself as most suitable for employment is a flask of about 80 cub. centims. capacity, with a cork inserted into the neck, through which a delivery tube from a Mohr's burette, graduated in tenths of a cub. centim., passes for dropping in the product to be examined. Through the cork, also, there must be an exit tube for the escape of air and steam from the flask. Should it be desired to avoid the impregnation of the surrounding atmosphere with ammonia, the exit tube may be connected by vulcanised tubing with a U-shaped tube containing fragments of pumice stone moistened with water or a weak acid. The burette being fixed in the stand, the flask is allowed to hang suspended, so that there may be nothing to obstruct the full view of the contents. The heat is applied by means of the flame of a spirit-lamp, and the best position for watching the disappearance of colour is by the light reflected from a white background specially provided for the purpose. It is convenient to have another burette, graduated in cub. centims., and of 100 cub. centims. capacity, fixed in the stand for holding and delivering the ammoniated copper solution. Messrs. Griffin, of Garrick Street, have constructed an arrangement to meet the requirements.

I at first took it for granted that in the action occurring the same relation existed between the amount of oxide of copper reduced and that of sugar oxidised, as under the employment of the copper test in the ordinary way, viz., that 5 atoms of oxide of copper were reduced by 1 atom of sugar, and the liquid I first employed was prepared by adding to 100 cub. centims. of Fehling's solution 300 cub. centims. of strong solutions of ammonia (sp. gr. 0.880) and 600 cub. centims. of distilled water. The liquid thus made contained one-tenth of Fehling's solution, and if it compared itself in the same manner as the latter, 10 cub. centims. of it would stand equivalent to 0.005 grm. of grape sugar. In working with this liquid the results obtained were so accordant in relation to each other that I had no misgiving about its uniformity of action; but I felt that before being definitely accepted they ought to be checked against known amounts of sugar. The accomplishment of this proceeding, however, is not altogether unattended with difficulty, on account of the uncertainty of obtaining grape sugar free from impurity and in a perfectly dried state.

The method I have adopted has been to operate upon weighed amounts of cane sugar and produce inversion by boiling with an acid. I first found that the cane sugar, which is sold in coarse colourless crystals—that which is known as "white crystal," and used for sweetening coffee—stood the test on examination for purity with Laurent's polarimeter. A weighed quantity was taken, and, after being inverted by boiling with hydrochloric acid, the acid neutralised, and the liquid brought to a known volume, subjected to treatment with the ammoniated copper liquid. Repeated trials were made with varying quantities, and it was found that the results stood in harmonious relation to each other, but that the amount of sugar indicated was larger than the calculated amount of invert sugar from the weighed quantity of cane sugar taken. At first I was at a loss for an explanation of this result, but subsequent

† *Gazette Hebdomadaire de Médecine et de Chirurgie*, September 14, 1877, p. 454.

observation has revealed that in the case of the ammoniated liquid, 6 atoms of oxide of copper are appropriated by 1 atom of sugar, instead of 5, as in that of Fehling's solution used in the ordinary way. When the reckoning is made upon this basis the results exactly correspond with the actual amount of sugar known to be present. Moreover, with solutions of ordinary grape sugar and diabetic sugar, examined comparatively with Fehling's solution used in the ordinary way and the ammoniated copper liquid, the results exactly accord under the reckoning that 5 atoms of oxide of copper are appropriated in the one case and 6 atoms in the other by 1 atom of sugar.

To be quite satisfied upon this point, a large number of observations under varying conditions have been made, and whilst what I have stated holds good for the ammoniated copper liquid prepared from Fehling's solution, without any further addition of alkali, and with the addition of potash to the extent of 1 grm. to 20 cub. centims. of the ammoniated test, yet a larger quantity of potash alters the action, and with 5 grms., and anything beyond, the behaviour is brought to the same as that of Fehling's solution used in the ordinary way, viz., 5 atoms only of oxide of copper are appropriated by 1 atom of sugar. With quantities of potash between the 1 and 5 grms., the results stand between the 5 and 6 atoms of cupric oxide.

I may mention that observation has further shown that whilst glucose prepared from starch behaves like other varieties of grape sugar, there is an intermediate product formed before the completion of the process of conversion, which behaves in a different manner from invert sugar, grape sugar, and sugar of diabetes. Estimations made with the ammoniated copper liquid coincide with those made with Fehling's solution without the presence of ammonia, and the addition of potash to the ammoniated liquid produces no modification of the result.

In order that the ammoniated copper liquid may be brought to the same standard of sugar value as Fehling's solution, and it is desirable that this should be the case, the proportion of copper must be increased so as to give 6 atoms against 5. By taking 120 cub. centims. of Fehling's solution, 300 cub. centims. of strong ammonia (sp. gr. 0.880) and making up to a litre with distilled water, the proper proportion is obtained, and the ammoniated liquid gives results corroborated in accuracy by the balance, and coinciding with those obtained by Fehling's solution employed in the ordinary way.

As a minor point it may be remarked that the diluted state presented by the ammoniated liquid offers an advantage by diminishing the liability to error arising from any want of absolute precision in measurement.

Twenty cub. centims. of the ammoniated copper solution, corresponding with 0.020 grm. sugar, having been run in from the burette containing the test, the flask is adapted to the cork attached to the delivery tube of the other burette containing the saccharine product for examination. The flame of a spirit-lamp is then applied underneath, and the contents of the flask brought to a state of ebullition and allowed to boil for a few minutes in order to get rid of the presence of air. The saccharine product is now allowed to drop from the burette until the blue colour of the test is just removed, and a perfectly colourless limpid state produced.

On account of the ammoniated copper solution used being only equivalent to 2 cub. centims. of Fehling's solution, it is necessary that the product to be examined should not be in too concentrated a form. For delicate observation it is convenient that the dilution should be such as to require the employment of from about 10 to 20 cub. centims. to decolourise the 20 cub. centims. of the ammoniated copper solution.

The ammoniated copper solution enjoys the advantage of possessing a self-preservative power. It is well known in the case of Fehling's solution that, in the course of time, not only does the liquid become impaired in stability, but actually reduced in strength, by the spontaneous

deposition of a certain amount of suboxide. Not so, however, with the ammoniated liquid. Here the conditions are such that under exposure to air the copper cannot fail to remain in solution and to be maintained in a fully oxidised state. A further advantage is given by the influence of the presence of ammonia on the colour of the test, for, in proportion to the height of colour of a volumetric liquid, so is its degree of delicacy as a reagent, and the effect of the addition of ammonia to the ordinary copper test is to considerably increase the blue colour belonging to it.

Seeing that the test here proposed acts with equal efficiency either in the presence or absence of extraneous organic matter, it is alike adapted for employment by the chemist, the physiologist, and the medical practitioner in relation to diabetes.

THE PREPARATION OF SINGLE REGULAR CRYSTALS OF ANY DESIRED SIZE.*

MR. FERDINAND MEYER, who has for thirty years studied the conditions necessary for obtaining large, single, and regular crystals of chemical salts, has published his method in the *Archiv der Pharmacie*, October, 1878, from which we take the following:—

Prepare a solution of any salt in water of such a strength that, after standing twenty-four hours, a portion of the salt will separate in crystals. Pour off the mother-water, select a few of the best formed crystals, and place them on a plate of glass, which lies in a rather tall vessel. Then re-dissolve a little of the dry salt in a small quantity of the mother-water, add this supersaturated solution to the main bulk of the mother-water, pour this upon the crystals on the plate of the glass, and place the vessel into a room where the temperature remains as uniform as possible, best in the cellar. The temperature of the room should be ascertained by a thermometer, and in case of any changes of temperature, a further quantity of the salt is to be dissolved in the mother-water. This must be repeated every twelve or fourteen hours, until the crystals have reached the desired size. If the solution is too strong, single regular crystals are seldom obtained at once, but this is generally of no consequence, for, as long as one side at least is perfectly formed, it is only necessary to turn them two or three times to cause the other sides likewise to become perfect. As the crystals increase in size care must be taken to give them a correct position in the plate of glass: and, if the solution is at all concentrated, the crystals must be carefully freed from adhering irregularities, and then replaced in the solution.

In a solution of alum, a very oblique octoëder is usually obtained first. This may be allowed to reach a considerable size, after which it is to be laid successively on the narrow sides, when it will gradually become a regular octoëder. If it is always kept lying on the broadest sides it will continue to grow obliquely.

It is well known that several isomorphous salts may be crystallised, one over the other, in layers, without a change of crystalline form. Chrome-alum crystals may thus be covered with crystals of ordinary alum. The largest crystal of this kind obtained by the author weighed over three pounds.

The author also observed that, when employing the same mother-water for a considerable time, the crystals began to show blunt or flattened points. This happened with regular as well as with oblique crystals, so that in place of eight surfaces, the regular crystals gradually assumed sixteen equal sides, and the irregular ones, fourteen smaller and two larger sides. If, however, the mother-water be acidulated with a little sulphuric acid, this flattening of the point occurs but rarely.

* From "New Remedies," January, 1879.

As a general rule, this changing the position of the single crystals of any salt, but particularly of sulphate of zinc, copper, nickel, or magnesium, and of Rochelle salts, different forms of the same system are obtained. If crystals of Rochelle salt, which may easily be obtained of large size, are always placed upon one and the same side, one-half of the crystal will become perfectly developed; but if they are laid, alternately, upon the two opposite long surfaces, the development is less regular. On placing large crystals of the same salt, even if only half developed, lengthwise into the liquid, alternately upon either end, development of the lateral surfaces proceeds very regularly.

It is not advisable to introduce crystals into a solution if the latter is at all warm, or to pour a warm solution into a cold one containing crystals, as the latter are thereby generally torn or broken. If a portion of a crystal has been by accident broken off, it may be repaired by subjecting it to the above-detailed process. In a crystal of chrome alum, from which a piece weighing ten grms. had been broken off, the gap was completely restored by subjecting it to the feeding process for a fortnight.

As soon as the crystals have attained the desired size it is best to place them into less concentrated solutions, in a slightly cooler place; this after-treatment causes the surfaces to become smooth and levelled, and the edges to become sharp.—*Pharmaceutical Journal*.

ANALYSIS OF BLEACHING-POWDER.

By GEORGE WHEWELL, F.I.C., F.C.S.

BEING requested some time ago to make an analysis of an unsatisfactory sample of commercial bleaching-powder, and finding it to absorb moisture very rapidly, I made the following experiments, which I think might interest your readers.

The rate of absorption was determined by exposing 100 grs. to the atmosphere of the laboratory and weighing every two hours during the day.

In 24 hours it absorbed 25 per cent of moisture.

" 48	"	"	41	"	"
" 72	"	"	52.3	"	"
" 96	"	"	64.9	"	"
" 103	"	"	69	"	"

A small quantity now left is in a liquid condition.

The sample was sold as containing 35 per cent of available chlorine, but was found to only contain 28.6 per cent. Its percentage composition was:—

Calcium..	..	..	..	..	30.88
Chlorine	..	..	..	..	58.13
Difference (oxygen, &c.)	..	..	..	..	10.99

100.00

The calcium was determined as carbonate, and the total chlorine as chloride of silver.

ALUM IN FLOUR AND BREAD.

By M. D. PENNEY, F.C.S.

THE quantity of alumina naturally present in pure flour and bread has been a subject of discussion for many years, and has been erroneously assumed by some chemists not to exceed an amount equal to 8 or 10 grains of alum per 4 lbs. At a meeting of the Society of Public Analysts, February 5, 1875, it was stated by one speaker to be as low as 2 grs., and by others as high as 10 grs., expressed as alum per 4 lbs. of bread; and a rather prominent analyst asserted at the "Selby case" a few months ago that, in his opinion, 2 grs. were quite sufficient to allow for. It has recently

become apparent that the attempt to fix upon a standard must be abandoned, and perhaps some experiments made by me last April and May, may assist to throw more light on the question.

TABLE I.
Six Samples of Flour.

No.	Grains per 4 lbs.		
	Alumina expressed as Alum.	Ferric Oxide.	Siliceous Matter.
1.	24.30	5.47	50.00
2.	21.75	6.06	55.00
3.	21.25	4.90	56.00
4.	17.00	5.20	40.00
5.	12.40	5.30	30.00
6.	6.34	4.77	22.00

In the first table are the analyses of six pure flours. I was satisfied that they were quite free from alum, and yet I found alumina equal in No. 1 equal to 24.30 grs. of alum per 4 lbs.

The first four flours came from a large mill where much foreign grain is used, and No. 6 was made at a small country mill from English grown wheat alone. It occurred to me that the quantity of alumina in flour might depend on the variety of grain from which it was prepared; and with a view to ascertain if such were the case, I made several analyses of wheats from different countries, and have tabulated the results.

TABLE II.

No.	Variety of Wheat.	Milligrams. per 100 grms.		
		Phos. of Alumina.	Phos. of Iron.	Siliceous Matter.
1.	Calcutta	24.30	18.10	164.00
2.	Ditto	21.00	15.16	184.00
3.	Ditto	18.50	20.00	170.00
4.	Kourish	27.20	34.00	206.00
5.	Ditto	31.00	36.00	226.00
6.	Russian	17.20	20.00	101.00
7.	Ditto	24.45	17.20	131.00
8.	Ditto	13.10	11.40	70.00
9.	Ditto	16.35	16.34	126.00
10.	Chicago	4.00	9.00	48.00
11.	Oregon	4.00	8.11	36.00
12.	English	5.12	7.40	35.00
13.	Ditto	6.40	14.20	40.00
14.	Ditto	7.30	14.00	30.00
15.	Ditto	3.80	4.70	32.00
16.	Stetin	16.33	26.40	109.00
17.	Ditto	13.24	21.23	120.00
18.	California	3.00	2.21	31.00
19.	11 varieties mixed	15.10	12.30	59.00
20.	Egyptian as impd.	167.00	64.50	370.00
21.	Ditto, hand picked	49.49	27.20	117.00
22.	Ditto, washed ..	14.10	6.36	101.00

Nos. 1, 2, 3 are Calcutta wheats, now largely imported and much prized by millers. The following six refer to Russian wheat. The Kourish variety is particularly high in alumina and silica. Nos. 10 and 11, and the English wheats, Nos. 12 to 15, are very much alike. No. 18 was a sample of Californian wheat, a pretty looking, large, white grain, remarkably low in alumina and iron oxide. No. 19 was a mixture of 11 varieties mixed by a miller preparatory to grinding. Egyptian wheat, as imported, is much intermixed with clay. It seems that the lighters in which it is carried on the Nile are unprovided with hatches, and in lieu of them the cargo is covered with mud, which is soon baked hard in the sun and gives a firm footing to the boatmen. This rough treatment accounts, no doubt, for its presence in the form of dust, pellets, and lumps. It is always more or less cleansed preparatory to grinding; but it does not appear practicable, with the cleansing apparatus attached to the best constructed mills, to get rid of all the extraneous matter in

grain. Sometimes the holes made by the weevil (an insect infesting some kinds of wheat, Calcutta for instance) are filled with dirt, and no amount of working or screening will extract it.

A glance at the table will show what kind of flour to expect from any of the wheats. It is rarely, however, that any one kind is ground by itself. It is the practice of millers to mix several kinds, and the mixture varies in every mill and in every part of the county according to the supply of foreign grain and the quality of our home-grown.

No. II. Table shows that some varieties of wheat are more contaminated than others with alumina. I use the word contaminated advisedly, as I believe that the greater portion of it is due to extraneous matter, and it reveals the source of the excessive quantity of alumina occasionally met with in flour.

Since it is impossible to fix upon a standard of natural alumina, and since it is erroneous to regard its amount, even in the presence of alum, as in any degree a measure of alum, it may be asked—What is the use of estimating it at all?

I venture to suggest that it might indicate whether the grain was or was not cleansed properly before grinding; but the estimation of silica would answer just as well. Experience will enable us, perhaps, to decide on the limit to allow for clay in flour. If a line were drawn somewhere it would probably make millers more careful in the cleansing process.

Dr. Dupré's "chloroform" method of separating alum from flour appears from his reports to be satisfactory. A correct quantitative test for alum in bread is still a desideratum. As for a qualitative test, there cannot be anything more simple and certain than the logwood test properly applied. I have tried it repeatedly with different kinds of flour and bread, and never found it to fail. It does not matter, in my opinion, whether the solution is new or old, and all the logwood chips I have come across answer well. I have never found any difficulty in distinguishing the alum colour from that caused by soil, magnesia, or any probable constituents of flour or bread. I therefore place implicit trust in it, and feel rather surprised that its efficiency is sometimes questioned.

Hull, January 31, 1879.

ON THE FORMATION AND COMPOSITION OF SOME COMPLEX OXIDES OF COBALT AND NICKEL.*

By THOMAS BAYLEY, Assoc. Royal Coll. of Science, Ireland.
Demonstrator of Practical Chemistry, Analysis, and Assaying in the
Mining School, Bristol.

WHILE preparing standard solutions of nickel and cobalt salts for the purposes of a research on the colorimetric relations and on the colorimetric estimation of those metals, I was endeavouring to use a modification of the method of estimating nickel and cobalt, indicated by Bunsen†, depending for their determination on the iodine liberated by the higher oxides of these metals in contact with hydrochloric acid and potassium iodide. The method was as follows:—The solution of the nickel or cobalt salts was made alkaline by soda and then mixed with excess of sodic hypochlorite obtain by the action of cold dilute sodic carbonate on fresh bleaching-powder.

After allowing the slightly warm solution of nickel or cobalt to stand some time, so as to ensure complete oxidation, the temperature was raised until brisk effervescence ensued, and the solution allowed to remain at that temperature until the excess of hypochlorite was decomposed. When the evolution of oxygen had ceased, the liquid was

boiled for about half an hour. I found that by this process, it is easy to destroy all matter, except the oxide, capable of liberating iodine on treatment with potassic iodide and hydrochloric acid. The solution having been cooled, it was mixed with excess of potassic iodide, and then with enough hydrochloric acid to dissolve the suspended oxide. The liberated iodine was then estimated by a standard solution of sodic thiosulphate ($\text{Na}_2\text{S}_2\text{O}_3$).

In the first experiments I used a standard solution of nitrate of nickel, and calculated the nickel from the iodine set free according to the following equation:—

The results were not satisfactory, as will be seen from the following Table:—

Nickel used.	Nickel found.
Grm.	Grm.
0.1570	0.1437
0.1570	0.1580
0.1570	0.1465
0.1570	0.1568
0.1570	0.1639
0.1570	0.1541

Besides these analyses there were several which yielded a far less quantity of nickel. The same method was then applied to cobalt, with this difference, that the solution was boiled only for a few minutes, as I found that length of time sufficient for the decomposition of the last traces of hypochlorite. The amounts of iodine liberated were much greater than would be due to the oxide Co_2O_3 , while they agreed perfectly with an oxide Co_3O_5 , thus:—

Cobalt used.	Iodine liberated.	Theory of Iodine for Co_3O_5 .
Grm.	Grm.	Grm.
0.1865	0.5338	0.5343
0.1865	0.5380	0.5343
0.1865	0.5328	0.5343

I now repeated the experiments with nickel, taking care to boil the liquid only a minute or two. In one or two instances it was not boiled, but the precipitate filtered off and washed. The results were as follows:—

Nickel used.	Iodine liberated.	Theory of Iodine for Ni_2O_3 .
Grm.	Grm.	Grm.
0.1570	0.4428	0.4521
0.0785	0.2263	0.2260
0.1835	0.5318	0.5284
0.1570	0.4490	0.4521

With a mixture of 0.1863 gram. cobalt, and 0.1835 gram. nickel:—

Iodine found.	Theory for Iodine due to Ni_2O_3 & Co_3O_5 .
Grms.	Grms.
1.0532	1.0627

In the last cases the oxides were not boiled, but the solution was allowed to stand over the steam bath for a few hours.

With solutions of known quantities of nickel I now made the following experiments. The solution with the suspended oxide was boiled for some hours.

Nickel used.	Iodine found.	Theory of Iodine for Ni_2O_3 .
Grm.	Grm.	Grm.
0.1835	0.2009	0.2642
0.1835	0.1812	0.2642
0.1835	0.2321	0.2642
0.1835	0.3310	0.2642
0.1835	0.2830	0.2642
0.1835	0.3765	0.2642
0.1835	0.1069	0.2642

In the last experiment the solution was boiled for a few days.

* A Paper read before the Royal Irish Academy, June 25, 1877.
† *Ann. Ch. Pharm.*, lxxvi., 265.

A quantity of cobalt nitrate was now mixed with soda and sodic hypochlorite, and allowed to stand in a warm place until effervescence had ceased. The precipitated oxide of cobalt was then well washed with warm water and dried, till constant, under the air pump, over strong sulphuric acid.

A sample of this oxide was then submitted in succession to various temperatures. The results were as follows:—

Grm.	Grm.
Oxide taken 0.9278 ($\text{Co}_3\text{O}_5, 4\text{H}_2\text{O}$)	
Oxide dried at 100°C . } 0.8760 Theory for $\text{Co}_3\text{O}_5, 3\text{H}_2\text{O}$..	0.8770
Do., 138°C . } 0.8223 " " $\text{Co}_3\text{O}_5, 2\text{H}_2\text{O}$..	0.8263
Do., 310°C . } 0.7548 " " $\text{Co}_3\text{O}_5, \text{H}_2\text{O}$..	0.7756

After this experiment there was an appearance of change on the surface of the oxide.

Grm.	Grm.
Oxide after ignition to redness ..	0.6840 Theory for Co_3O_4 ..
	0.6798

Another portion of the same sample:—

Winkelbleck obtained an oxide in the same way as I prepared my samples, only that he boiled his with strong potash before washing it. He dried his oxide over strong sulphuric acid. According to him, the formula is $\text{Co}_2\text{O}_3, 3\text{H}_2\text{O}$. His results were as follows:—

	Per Cent.	Per cent.
	(I.)	(II.)
2Co ..	53.83	53.93
3O ..	21.62	21.46
$3\text{H}_2\text{O}$..	24.26	24.61
		53.64
		21.82
		24.54

The question, which is the true formula of the oxide I obtained, is determined by the amount of iodine liberated by the oxide on treatment with potassic iodide and hydrochloric acid. According to the formula $\text{Co}_2\text{O}_3, 3\text{H}_2\text{O}$, there should be liberated 0.402 grm. by 0.1865 grm. of cobalt; according to the formula $\text{Co}_3\text{O}_5, 4\text{H}_2\text{O}$, 0.5343 grm. should be liberated. I found in three experiments 0.5338, 0.5380, and 0.5328.

When the oxide $\text{Co}_3\text{O}_5, 4\text{H}_2\text{O}$, obtained as described above, is boiled for an hour or two in the solution in which it is precipitated, and the amount of iodine liberated then estimated, the result points to the formation of the oxide $\text{Co}_{12}\text{O}_{19}$, intermediate between Co_3O_5 and Co_2O_3 .

On attempting to prepare Ni_3O_5 in the dry state by precipitating, washing, and drying *in vacuo*, I found that the moist precipitate gave off oxygen as soon as the liquid in which it was precipitated was removed. The moist precipitate was allowed to stand some days, and then left over the air-pump for about a week, in order to allow time for this change to be complete. Owing to some interruption, I have as yet had time to prepare only one sample by this means. The results of the analysis agree closely with the formula $\text{Ni}_8\text{O}_{12}, 9\text{H}_2\text{O}$, one-ninth of the water being lost at 100°C .

Summary.

Under the influence of the hypochlorite solution nickel and cobalt form the oxides Ni_3O_5 and Co_3O_5 . On boiling the liquid containing Co_3O_5 it loses oxygen, and passes to the form $\text{Co}_{12}\text{O}_{19}$, intermediate between Co_2O_3 and Co_3O_5 . Under similar circumstances, Ni_3O_5 appears to decompose without forming stable lower oxides, although it is probable from the results that the formation of Ni_2O_3 is a stage in the process. The oxides Co_3O_5 and $\text{Co}_{12}\text{O}_{19}$ appear to be stable at a low red heat: they are distinguished from Co_3O_4 by a slight difference of colour. Co_3O_5 has the following hydrates:—

and probably,

Ni_3O_5 decomposes while still moist when its precipitating liquid is removed by washing. In the one experiment which was made, the resulting dried compound agreed closely with the formula $\text{Ni}_8\text{O}_{11} \cdot 9\text{H}_2\text{O}$. I have found that when $\text{Co}_3\text{O}_5 \cdot 4\text{H}_2\text{O}$ is treated with cold dilute nitric acid part is dissolved with evolution of oxygen, and that part remains insoluble. I hope, in a future paper, to give the results of some similar experiments undertaken for the purpose of determining the proximate constitution of these oxides.

It may at first sight appear that the formula $\text{Co}_{12}\text{O}_{19}$ is inadmissible on account of its complexity, but as the iodine method clearly shows that the oxide is exactly intermediate between Co_3O_5 and Co_2O_3 , and as the formula $\text{Co}_{12}\text{O}_{19}$ is the simplest formula for such an oxide, it would seem that we must accept it, especially when we consider the tendency of cobalt to form compounds vieing in complexity with many of the products of organic chemistry. It may be that the application of the iodine method to the examination of the oxides of other metals would lead to the acceptance of formulæ more complex than those now admitted. The two oxides of cobalt described in this paper, and indeed other oxides of cobalt, may be represented graphically by rings somewhat analogous to the well-known benzene "ring" of the aromatic carbon compounds and to the zinc "ring." Thus—

This investigation was conducted in the Chemical Laboratory of the Royal College of Science, Dublin.

Further Note.—I have found by experiment that when any of these peroxides are decomposed by hydrochloric acid, and the evolved chlorine passed into a solution of potassic iodide, the amount of iodine liberated is exactly equal to that which is liberated by decomposing the same weight of the peroxide in a solution containing potassic iodide. The presence of caustic alkali in large quantity appears to retard the passage of Co_3O_5 into $\text{Co}_{12}\text{O}_{19}$ during the boiling process. Co_3O_5 , indeed, seems to be more stable in proportion as the amount of free alkali is greater.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

The fruit when ripe contains 10 per cent of cane-sugar and 3 per cent of inverted sugar.

Application of His Atomic Theory to Certain Minerals.—A. Gaudin.—Nothing short of a full translation could give a satisfactory view of the speculation contained in this paper.

Displacement of Spectral Rays Due to the Rotatory Movement of the Sun.—L. Thollon.—The author by making use of his newly invented spectroscope has observed a displacement of the solar rays perfectly well defined, and evidently approaching to the results of calculation.

Radiation of Incandescent Platinum.—J. Violle.—The author has made a number of measurements of the intensity of the red light emitted by platinum at different temperatures, from 900° to 1775° , the melting-point of the metal. The intensity of the red light, scarcely sensible at 500° , increases at first very rapidly and then more slowly. At 2910° its intensity is not greater than at the melting-point of silver.

Illumination of the Lines of Molecular Pressure and the Trajectory of Molecules.—W. Crookes, presented by Th. du Moncel.—The substance of this paper has appeared in the *CHEMICAL NEWS*, vol. xxxviii., p. 279.

Electro-dynamic Phenomena and in Particular on Induction.—H. de Meaux.—The author concludes that in a closed circuit the intensity of a given current cannot be changed by the induction of an indefinite cylindrical conductor upon another of the same form by surrounding one or other of these conductors, or even both, with a concentric metallic covering communicating with the ground in its whole length.

A New Bell's Telephone, with a Loud Voice.—M. Gower.—The peculiarities of this instrument are said to be due to the fact that the poles are placed as in Faraday's electro-magnet. The diaphragm is thicker, larger, and tighter than those commonly constructed. The case containing the whole is metallic, and forms a sounding-chest, and is furnished with a bell mouth which amplifies sound

On Amalgams of Chrome, Manganese, Iron, Cobalt, and Nickel, and a New Process for Preparing Metallic Chrome.—H. Moissan.—If a concentrated solution of chromous chloride is shaken up in water with sodium amalgam, a part of the sodium decomposes water, gives off hydrogen, and forms soda, which precipitates a certain quantity of chrome. The other part of the amalgam produces by double decomposition chloride of sodium and an amalgam of chrome. To be certain that no sodium remains in the mercury the amalgam obtained is kept for an hour in boiling water, stirring from time to time. If this amalgam is heated in a current of hydrogen to 350° metallic chrome is left as a black amorphous slightly coherent substance. The same method serves for preparing amalgams of manganese, iron, cobalt, and nickel.

Preparation of Methyl-formic Ether and Pure Methylic Alcohol.—MM. Bardy and Bordet.—Not suitable for abstraction.

Active Principles of *Sarracenia Purpurea*.—F. Hétet.—From this plant the author has extracted an alkaloid whose characters agree with those of veratrin. It is curious that the *Sarracenia*, though belonging to a remote family, should contain a poison similar to that of colchicum.

Physiological Action of so-called "Garnet"—the Residue of the Manufacture of Magenta.—M. Jousset de Bellesme.—This substance dissolved in treacle is much more used for colouring wines than is pure magenta, which would give a shade too much bordering upon a rose. In a number of experiments made upon animals this colour always produced fatal results. One c.c. proved fatal to a cat in twelve days. The symptoms are persistent diarrhoea and rapid wasting.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin
No. 14, 1879.

Action of Hydrochloric Acid upon Certain Double Salts of Sulphuric Acid.—C. Hensgen.—The author divides the double sulphates into three classes: those in which each of the sulphates present is decomposable by hydrochloric acid; those in which one of the sulphates only is attacked; and those in which neither of the component sulphates is affected. He has, in the first place, studied the behaviour of potassio-cupric sulphate, of potassic iron, alum, and of ammonio-ferrous sulphate.

Iso-heptylic Acid from β -Hexyl-iodide.—Otto Hecht and J. Munier.—Iso-heptylic acid is a limpid oily liquid of faintly rancid odour, sparingly soluble in water, and boiling at 211° to 213°.

Synthesis of Meta-nitro-cinnamic Acid.—R. Schiff.—The author obtains this acid by heating a mixture of equal molecules of nitro-benzaldehyd, anhydrous acetic acid, and sodic acetate for eight hours in a vessel provided with an ascending cooler.

On Acetylen Urea.—C. Böttiger.—A further examination of bodies which the author obtained last year on treating urea with glyoxal in presence of hydrocyanic acid.

On Hydroxylation by Direct Oxidation.—R. Meyer.—Not susceptible of useful abstraction.

On Oxypropyl-benzoic Acid and its Derivatives.—R. Meyer and J. Rosicki.—A closer examination of the acid in question, which one of the authors recently obtained by the oxidation of cuminic acid.

Explanation on the Formula of Uric Acid.—R. Fittig.—A question of priority.

New Analyses of the Mineral Springs of Passug, Solis, and Tiefenkasten in the Canton Grisons, Switzerland.—A. von Planta-Reichenau.—Six pages of analytical results; possibly of medical interest.

Specific Rotation of Cane-sugar.—B. Tollens.—An important paper, but not susceptible of useful abstraction.

Further Observations on Pyrrol and its Derivatives.—Chichester A. Bell.—An examination of the so-called ethyl-pyrrol of Lubawin, and of its behaviour with hydrochloric acid and with bromine.

Camphen Derived from Camphor, and the Synthesis of its Homologues.—F. V. Spitzer.—This paper treats of the camphen obtained from the most infusible camphor-bichloride, and on ethyl-camphen and isobutyl-camphen.

Camphor Chlorides.—F. V. Spitzer.—The camphor-bichloride discovered by the author is readily soluble in alcohol and ether. It melts at 155° to 155.5°. If preserved in a somewhat moist condition it easily gives off hydrochloric acid.

Cinchonic Alkaloids.—A. Claus.—Not adapted for abstraction.

Imido-thio-ether.—A. Pinner and F. Klein.—This product is obtained by a reaction to that which yields imido-ether.

Reimann's Färber Zeitung,
No. 1, 1879.

This issue gives a very dismal account of the condition of the once so prosperous and celebrated print-works of Alsace.

No. 2, 1879.

A silk merchant in Zurich is somewhat roughly handled for having advertised his silks as "pure" and for having called public attention to the weighting system, which Dr. Reimann declares is carried "only to the extent of 150 per cent."

Since the cultivation of madder in France has dwindled to about one-eighth of its former extent it is proposed to abolish the red trousers of the French army.

There is the commencement of a review of the specimens of calico-printing at the late Exhibition. Several English exhibitors are praised, but we note the remark that none of the English furniture-prints display the fiery red which is so admired in French work.

No. 3, 1879.

Following up the example about to be set by France it is proposed that the blue coats and grey trousers of the German army should be abolished, as they necessitate the use of indigo, and that alizarin browns or blacks should be used in their stead.

No. 4, 1879.

The principal articles in this issue are a dissertation in favour of protection and complaints of injustice, or, at least, negligence, in the award of prizes at the late Paris Exhibition.

It is announced that the financial condition of the Berlin Dyers' Association is very unsatisfactory.

No. 5, 1879.

There is here an account of the sophistication of soaps with rosin, potato-flour, silicate of soda, and alumina, all of which additions except the last are declared to be positively injurious.

Les Mondes, Revue Hebdomadaire des Sciences.
No. 3, January 16, 1879.

The Telemachon.—W. Wallace, of Connecticut, is said to have invented a new apparatus under this name by which motive power can be conveyed many hundred miles without loss or difficulty.

The Teleroscope.—M. Senlecq, of Ardres, has submitted to the examination of M. du Moncel a project for re-producing telegraphically at a distance images obtained

in the camera. The apparatus is based upon the property possessed by selenium of offering an electric resistance variable according to the degrees of light.

No. 4, January 23, 1879.

A man is said to have died in great torment from having struck a match upon his thumb-nail, when a minute fragment of phosphorus lodged under the nail and brought on a violent inflammation, which extended to the shoulder.

According to the *Revue Britannique* ether is in common use as a stimulant in Drapers' Town, in Ireland, where its odour can be recognised at the distance of half a mile! The grass in Hyde Park is said to be strewn with empty ether-bottles which ladies of fashion have thrown out of the windows of their carriages.

M. Audouin recommends chromic oxide as the most refractory material known for fire-bricks, crucibles, &c. It resists the highest known temperatures, and is attacked neither by oxides of iron nor by silica.

No. 5, January 30, 1879.

According to Dr. Draper the rain-fall at New York has been continuously decreasing since 1869.

No. 6, February 6, 1879.

French Production of Wine.—The total production of wines for 1878 was 48,000,000 hectolitres, and that of cyder and perry 12,000,000. Half a million hectares of vineyards have been annihilated by the phylloxera.

It appears that "green oysters" are sometimes fraudulently prepared by steeping them in a solution of a salt of copper.

Simple Method of Detecting Magenta in Wines, Fruit-syrups, &c.—Prof. Flückiger adds to portions of the sample, dilute if needful, recently-prepared chlorine and bromine water. If genuine the colour in both becomes a faint yellow. If magenta is present chlorine produces a deep dirty tint and bromine a violet colour, followed in time by the formation of violet flocks. Neither reagent destroys the colour.

La Lancette Belge, January 15, 1879.

According to statistical returns, sulphate of copper has caused the death of 77 persons in Belgium during the last ten years. The phosphorus obtained from matches has proved fatal to 170, verdigris to 33, sulphuric acid to 30, and cantharides to 24.

MEETINGS FOR THE WEEK.

- MONDAY, 24th.—Medical, 8.
— Royal Geographical, 8.30.
— Society of Arts, 8. "Dwelling Houses: Their Sanitary Construction and Arrangements," by Dr. W. H. Corfield, M.A. (Cantor Lectures.)
— London Institution, 5.
TUESDAY, 25th.—Civil Engineers, 8.
— Royal Institution, 3. "Animal Development," Prof. Schäfer.
— Anthropological, 8.
WEDNESDAY, 26th.—Society of Arts, 8. "Indian Pottery at the Paris Exhibition," Dr. Birdwood, C.S.I.
— Geological, 8.
THURSDAY, 27th.—Royal, 8.30.
— Royal Institution, 3. "Sound," Prof. Tyndall.
— Philosophical Club, 6.30.
— London Institution, 7.
FRIDAY, 28th.—Royal Institution, 9. "The Sorting Demon of Maxwell," Sir W. Thomson.
— Quekett, 8.
SATURDAY, 29th.—Royal Institution, 3. "Lessing," by Reginald W. Macan.

CULLEY'S PRACTICAL TELEGRAPHY.
In One Volume, 8vo., with 132 Woodcuts and 18 Lithographic Plates of Machinery and Apparatus, Price 16s.

A HANDBOOK OF PRACTICAL TELEGRAPHY. By R. S. CULLEY, Member Inst. C.E. (Adopted by the Post Office and by the Department of Telegraphs for India.) The Seventh Edition, thoroughly revised and enlarged.

London: LONGMANS and CO.

WATTS'S DICTIONARY OF CHEMISTRY.

Seven Volumes, 8vo., price £10 16s. 6d.

A DICTIONARY of CHEMISTRY, and the Allied Branches of other Sciences; founded on that of the late Dr. Ure. By HENRY WATTS, B.A., F.R.S.; assisted by eminent Scientific and Practical Chemists.

"The English language is not rich in lexicons of science. We would point to this work as a model upon which others might be framed. To the practical analyst this work must prove of the utmost value—to the philosophical investigator it must, as the record of all former labours, be a great gain—and to the student who is true to his studies, it will prove an ever-ready guide. Our manufacturers know the value of chemistry, and are many of them experts in the special branches of the science which bear on their particular industries. They require to know the latest discoveries, and to keep them as it were in stock until the march of improvement renders it necessary to apply them. This 'Dictionary' places them in possession of these desiderata."—*Athenæum*.

THIRD SUPPLEMENTARY VOLUME

(VOL. VIII.), completing the Record of Chemical Discovery to the year 1877. In Two Parts, of which the First is now ready, pp. 844, price 36s. cloth.—Part II. in the Autumn.

"We cannot give this volume greater praise than by saying that it is worthy of the European reputation which Mr. Watts's 'Dictionary' has already acquired as a standard work of reference."—*Bristol Mercury*.

London: LONGMANS and CO.

COMPLETION OF THE SEVENTH EDITION.

Complete in Four Volumes, with 2500 Woodcuts, price £7 7s. cloth, or £8 16s. half-bound in Russia.

URE'S DICTIONARY of ARTS, MANUFACTURES, and MINES,

containing a Clear Exposition of their Principles and Practice. The Seventh Edition, re-written and enlarged. Edited by ROBERT HUNT, F.R.S., Keeper of Mining Records; assisted by numerous Contributors eminent in Science and familiar with Manufactures.

* Also VOL. IV. separately, completing the work to the present time, 8vo. with 440 Woodcuts, price 42s.

London: LONGMANS and CO.

PROFESSOR ALLEN MILLER'S CHEMISTRY.

ELEMENTS OF CHEMISTRY, Theoretical and Practical. By WILLIAM ALLEN MILLER, M.D., F.R.S., &c., late Professor of Chemistry in King's College, London.

PART I.—CHEMICAL PHYSICS, Sixth Edition, revised throughout, with additions, by HERBERT MACLEOD, F.C.S. 8vo., with 274 Woodcuts, price 16s.

PART II.—INORGANIC CHEMISTRY, Sixth Edition, revised throughout, with additions, by C. E. GROVES, F.C.S. 8vo., with 376 Woodcuts, price 21s.

PART III.—ORGANIC CHEMISTRY, New Edition, revised throughout, with additions, by H. E. ARMSTRONG, Ph.D., F.C.S., and C. E. GROVES, F.C.S. [In the press.]

London: LONGMANS and CO.

WORKS BY C. T. KINGZETT, F.I.C., F.C.S.

Recently published, in 8vo., with 23 Woodcuts, price 12s.

HISTORY, PRODUCTS, and PROCESSES

of the ALKALI TRADE, including the most recent improvements. By C. T. KINGZETT, F.I.C., F.C.S., &c., Consulting Chemist.

"The value of Mr. Kingzett's work is great, and it places the profession under a profound obligation."—*Chemical News*.

"We have no doubt that Mr. Kingzett's volume will enjoy the welcome reception it deserves, both at the hands of those more particularly interested in alkali and from the general public."—*Pharmaceutical Journal*.

"Those engaged in the trade, especially managers, will be best able to appreciate Mr. Kingzett's work. They will find in it not only a most interesting account of the history of what is going on every day before their eyes, but valuable hints and suggestions as to improved processes."—*Birmingham Daily Gazette*.

By the same Author, in 1 vol. 8vo., price 18s.

ANIMAL CHEMISTRY, or the Relations of Chemistry to Physiology and Pathology; a Manual for Medical Men and Scientific Chemists.

London: LONGMANS and CO.

PROF. ODLING'S CHEMISTRY FOR MEDICAL STUDENTS.

Now ready, a New Edition, illustrated with 71 Woodcuts of Microscopical Preparations and Chemical Apparatus, price 6s.

A COURSE of PRACTICAL CHEMISTRY, arranged for the use of Medical Students, with express reference to the *Three Months' Summer Practice*. By WILLIAM ODLING, M.A., F.R.S., Professor of Chemistry in the University of Oxford. Fifth Edition, thoroughly revised.

London: LONGMANS and CO.

THE
MONTHLY JOURNAL OF SCIENCE
AND ANNALS OF
BIOLOGY, ASTRONOMY, GEOLOGY, INDUSTRIAL ARTS
MANUFACTURES, AND TECHNOLOGY.

Edited by WILLIAM CROOKES, F.R.S., &c.

The first number of the Monthly Series (February, 1879) is
Now Ready.

Price One Shilling and Sixpence.
CONTENTS.

- I. "Progress"—The Alleged Distinction between Man and Brute.
 - II. Matter Dead—Roger Bacon and John Dalton.
 - III. A Contribution to the History of Electric Lighting. By W. Mattieu Williams, F.C.S., F.R.A.S.
 - IV. The Problem of Flight—Ballooning in Arctic Exploration.
 - V. Electric Lighting. By Prof. W. E. Ayrton.
 - VI. Instinct or Reason?
 - VII. New Achromatic Microscope.
 - VIII. Safe Anæsthesia.
 - IX. On the Transmission of Power by Means of Electricity. By Profs. Elihu Thomson and Edwin J. Houston.
- Correspondence—The Band-Pattern in Animals—The Sea-Serpent
Reviews of Scientific Works—Science Notes—Proceedings of Scientific Societies.

London: 3, Horse-Shoe Court, Ludgate Hill.

Appointment wanted by a Chemist of 15 years' standing. A good Analyst, and has had experience as Manager of Chemical Factory. Good testimonials. No objection to go abroad. Apply to F. I. C., care of Mr. W. J. Gordon, 15, Holborn Viaduct, London, E.C.

Manager of Tar and Ammonia Distillery will be disengaged on February 10, and will be open for Re-engagement. Advertiser has a good practical knowledge of the business, and is a steady energetic man.—Address No. 60, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Situation wanted by a Competent Analyst as Assistant or Principal. Good teacher. Apply, Public Analyst, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

CHEMICAL BALANCE.

Wanted, new or good secondhand, to turn distinctly with 1-200th of a grain, and having short pan for taking specific gravities.—Address, Box 7, Arbroath, N.B.

Wanted, a Situation in Chemical Works by a German Chemist, who has had a complete University education and some years practice in large Chemical Works on the Continent. First class references at hand.—Apply to S. 4017, care of M. Rudolf Moss, Cologne, Germany.

Wanted, by a Hungarian Gentleman, a Situation in a Drug House. Understands German, English, and book-keeping, and has a thorough knowledge of goods. Having good connections abroad would be glad to travel. Highest references.—L. S., 5, Cheverton Road, Hornsey Lane.

Wanted, in a Chemical Laboratory in London, a Partner with about £250; one acquainted with analyses of phosphates preferred.—Address, F.C.S., Messrs. Deacon and Co., 154, Leadenhall Street.

FOR SALE.—48 Plumbago Crucibles, assorted, Nos. 40, 60, 80, and 100; never been used; no reasonable offer refused.—Address, in first instance, G. Blower, 38, Whitmoreans, Wolverhampton.

ALLIANCE AND DUBLIN CONSUMERS'
GAS COMPANY.

The Directors of this Company are prepared to receive Tenders for the Tar produced on the Dublin Works, the quantity being about 800,000 gallons per annum. The Contract to be for three or five years, to commence on the 1st of March, 1880. Further information can be obtained on application to the undersigned, with whom Tenders are to be lodged on or before Tuesday, the 25th inst., endorsed "Tenders for Tar."

W. F. COTTON, Secretary and Manager.
Offices, 114, Grafton St.
February 6, 1879.

MR. COX, VALUER OF CHEMICAL PLANT, offers his services on the usual terms. Twenty years' experience. Estimates for all description of plant, plans, &c.—Glenmohr House, New Charlton London, S.

JUST PUBLISHED, 4th EDITION.

ros. 6d. cloth, Demy 8vo., pp. 420,

THE

PATENTEE'S' MANUAL.

A Treatise on the Law and Practice of Letters Patent, especially intended for the use of Patentees and Inventors.

BY

JAMES JOHNSON, ESQ.,

Of the Middle Temple, Barrister-at-Law, and

J. HENRY JOHNSON,

Solicitor and Patent Agent, Assoc. Inst. C.E. 47, Lincoln's Inn Fields, W.C., and Glasgow.

This Edition, much enlarged, gives a practical reference to every reported case of importance, and contains all the information on the law and practice of Patents Inventors and Patentees can require.

The Appendix contains the Statutes and Rules, and a summary of the Laws of all Foreign States and British Colonies.

London: LONGMANS and CO.

422 pp., Royal 32mo., French morocco, gilt edges, price 5s.

A POCKET-BOOK FOR CHEMISTS, CHEMICAL MANUFACTURERS, METALLURGISTS, DYERS, DISTILLERS, BREWERS, SUGAR-REFINERS, PHOTOGRAPHERS, STUDENTS, &c., &c. By THOMAS BAYLEY, Assoc. R.C. Sc. Ireland, Analytical and Consulting Chemist, Demonstrator of Practical Chemistry, Analysis, and Assaying, in the Mining School, Bristol.

Synopsis of Contents.

Atomic Weights and Factors—Useful Data—Chemical Calculations—Rules for Indirect Analysis—Weights and Measures—Thermometers and Barometers—Chemical Physics—Boiling-points, &c.—Solubility of Substances—Methods of obtaining Specific Gravity—Conversion of Hydrometers—Strength of Solutions by Specific Gravity—Analysis—Gas Analysis—Water Analysis—Qualitative Analysis and Reactions—Volumetric Analysis—Manipulation—Mineralogy—Assaying—Alcohol—Beer—Sugar—Miscellaneous Technological Matter relating to Potash, Soda, Sulphuric Acid, Chlorine, Tar Products, Petroleum, Milk, Tallow, Photography, Prices, Wages, &c.

London: E. and F. N. SPON, 46, Charing Cross.
New York: 446, Broome Street.

84 pages, with 136 Plates, demy 8vo., cloth, 30s.

PHOTOGRAPHED SPECTRA.—One Hundred and Thirty-six Photographs of Metallic, Gaseous, and other Spectra, Printed by the Permanent Autotype Process, with Introduction, Description of Plates and Index, and with an extra Plate of the Solar Spectrum (showing bright lines) compared with the Air Spectrum. By J. RAND CAPRON, F.R.A.S.

"... Mr. CAPRON has earned the thanks of Spectroscopists for the large amount of useful work which he has performed for them in the way of preliminary investigation. No exact scale or measurement accompany the photographs, and they will be chiefly useful in indicating by comparison with each other the lines which belong to particular metals and the conditions under which particular lines are produced. ... But although no exact measurements are given, and although the photographs vary very perceptibly in length, nearly all show lines which can be used as reference lines, by measurement from which the wave-lengths of the metal lines can be determined. ... The advantages of the photographic method are noticed by the author as follows:—'Absolute truth is everything in spectroscopic work, and the very best draughtsman, working with the most perfect micrometer, cannot, even at the expense of a vast amount of labour, equal in accuracy a good photograph of a set of spectral lines.' ... The photographs obtained from the electric light are particularly interesting. This is, as far as we know, the first extensive series of measurements of spectra obtained by the ignition of substances in the electric arc."—*Philosophical Magazine*.

London: E. and F. N. SPON, 116, Charing Cross.

ATTFIELD'S CHEMISTRY.

Adapted to the Medicine and Pharmacy of the United States.

H. C. LEA, 706 and 708, SANBORN STREET, PHILADELPHIA, has in the Press the EIGHTH EDITION, Revised from the Seventh Edition by the Author.

Publisher of English Editions—VAN VOOKST, London.

THE CHEMICAL NEWS.

Vol. XXXIX. No. 1005.

ON THE LIQUEFACTION OF GASES.*

By J. J. COLEMAN, F.I.C., F.C.S.

THREE methods have been employed in the liquefaction of gases:—I. Increase of pressure at normal temperatures. II. Abstraction of heat at normal pressures. III. The combination of these two operations. The gases which can be liquefied by pressure at normal temperatures are limited. Natterer showed us, some years ago, that under such conditions the enormous pressure of 3000 atmospheres was insufficient to liquefy hydrogen and oxygen. It was reserved for our countryman, Dr. Andrews, to demonstrate the fallacy of relying upon pressure alone for gaseous liquefaction. To use the words of Prof. Wurtz in his recent Faraday Lecture, he has shown us that with all vapours there is a point at which the molecular movements caused by heat finally gain the victory over the force of cohesion, whatever be the pressure to which the air is subjected. Dr. Andrews describes it as the "critical point;" Mendelejeff names it the "absolute boiling-point."

It is, therefore, easy to understand why Natterer failed and Cailletet and Pictet succeeded with their experiments. Indeed, it would appear from these researches, and the principles underlying them, and if it be taken for granted that the molecules of all gases have a tendency to gravitate to each other independent of external pressure, that of the two agents for effecting the liquefaction of gases the abstraction of heat is more efficacious than the application of pressure.

This is evident, and follows from the ordinary laws of gaseous expansion. It is a well-established fact that gases expand uniformly, and that the rate of expansion is such that a given volume of gas at the freezing-point of water will become double its bulk at 491° F. Therefore, if it be followed in its path of contraction for temperatures below freezing-point, by the time its temperature becomes reduced 491°, which is the absolute zero of physicists, the gas must necessarily be either liquefied or solidified. The greatest artificial cold yet produced has not exceeded about 220° below zero F.; but it would be rash to assume that it is impossible to produce greater cold. Indeed, it is not improbable that means may yet be found to produce cold sufficient to liquefy either oxygen or hydrogen at ordinary pressures. The question at once arises, what has already been done in the production of extremely low temperatures, and in what direction can such efforts be extended. But practice is dependent upon principles, and for principles we must fall back upon the mechanical theory of heat, thoroughly established and accepted universally by physicists, but as yet imperfectly understood by numbers of chemists educated in the old school of Black and Leslie.

It is useful in the outset to recal certain experiments of Dr. Joule; and, parenthetically, it may be observed that it is to be regretted that no collected edition of the papers of this able man has yet been published. In his paper read to the Royal Society in June, 1844, some very interesting experiments with compressed air are detailed. The paper commences by reference to the well-known fact that compressed air when expanded becomes cooled, that is, when it escapes into the atmosphere; but Dr. Joule asked himself this question—"Would the cooling effect be greater or less were the same air expanded into a vacuum?" He

answered the question by experiment. Two receivers were taken; one was filled with air compressed to about 20 atmospheres; the other receiver was exhausted by an air-pump. The two receivers having been connected by a short pipe in which there was a stopcock, the entire apparatus was immersed in a canful of water. Then by opening the stopcock the compressed air was permitted to flow from the full to the empty receiver.

The advocates of the old theory of heat would have said that since the compressed air in this operation dilated to twice its original volume heat must disappear to meet the increased capacity of air in consequence of its expansion. But the result, indeed, entirely contradicted this. There was no cooling effect whatever measurable by the most delicate thermometer, a result which certainly would have occurred had the compressed air been made to displace the atmosphere. In fact it has since been abundantly proved that the reduction of temperature which a compressed gas undergoes when allowed to expand into the atmosphere is owing to work done in displacing the atmosphere, which offers the well-known resistance of about 15 lbs. per sq. inch to the escape of the gas.

Putting the facts into a brief statement, it may be taken as proved that when a compressed air or gas is allowed to expand the greater the resistance, and consequently the work done in overcoming such resistance, the greater the resultant cooling effect produced. Expand a compressed gas into a vacuum, no cold is produced; expand it in opposing the atmosphere, some cold is produced; expand it against a resistance such as that of a heavily loaded piston so as to contribute to its motion, and the maximum cooling effect is produced. Sir W. Thomson, Rankine, and Clausius have worked out the whole subject mathematically, but it may be convenient to quote Clausius. He takes typical cases to illustrate the difference on the one hand of the expansion of a compressed gas as against the resistance of the atmosphere; on the other hand, as against the resistance of a loaded piston. Assuming an initial pressure of 5 atmospheres in each case, he shows that to bring the temperature of the expanded gas to the initial temperature before expansion, the first case would require 17 units of heat as against 74.9 required in the second case.

Long before the mechanical theory of heat was enunciated Dr. Gorrie utilised for freezing-machines the intense cold produced by expanding a gas behind a working piston. Though his theoretical ideas were somewhat confused, Charles Randolph noticed and commented upon it in the case of the compressed air-engine erected at Govan Colliery in 1849. Air compressed to 20 to 30 lbs. to the square inch was sent down a shaft 176 yards deep, and along a road about 700 yards long, where it was used for working an old steam-engine in the place of steam, the result being that the ports of the engine cylinder were frequently blocked up with ice.

The same phenomena can be observed in any kind of machinery worked with compressed air. In fact I have frequently observed the temperature of air issuing from the cylinder of coal- and rock-cutting machines to register fully many degrees below zero. Indeed, by such a process an unlimited reduction of temperature can be produced, provided the air or gas be subjected to sufficient compression before expansion, and supposing always that care be taken to remove the heat of compression by passing the compressed air through a surface condenser, kept cool with water, or by the actual injection of water at the time of its being compressed. When I first turned attention to the subject I exercised myself considerably in efforts to contrive a method of expanding air or gas so as to cause it to do the maximum of work in the act of expansion. But I speedily became convinced of the unlikelihood of anyone being able to invent a more perfect instrument for converting the expansion of an elastic fluid into work than is afforded by a well constructed steam-engine. Mallard shows us that compressed air made to do work in an engine, at an initial pressure of 10 atmo-

* A paper read to the Chemical Section of the Philosophical Society of Glasgow and to the Institute of Engineers (Scotland). Full drawings of the machinery will be found in the *Transactions* of the latter body, published in Glasgow.

spheres and temperature of 62° , should become reduced to -103° F. on being discharged, putting aside deductions for friction, &c. This illustrates the limitless production of cold by such a process; for let the initial pressure be higher, say 20 or 30 atmospheres, and the cooling effect will correspondingly be produced. Indeed, it seems to me that if Messrs. Pictet and Cailletet had in their experiments made the compressed oxygen or hydrogen do more work in expanding than the mere displacement of the atmosphere, then they would have been liquefied at much lower pressures. M. Pictet employed no less than 9000 lbs. pressure per square inch in his experiments. But it can be shown that a compression of only one-tenth of this, or 900 lbs. per square inch, raises a gas to 1200° F.; and that if gas so compressed be brought down to 60° , and then expanded in the act of doing work, it must necessarily be cooled down to a lower degree than any yet experimentally shown, and which would probably be sufficient to effect the liquefaction of any gas we are acquainted with.

Again, in their experiments there must have been a production of heat militating against the liquefaction from the friction of the gases in escaping into the atmosphere through a minute orifice.

This is the theoretical aspect of the case, but in practice several considerations arise.

It is very difficult constructing the necessary apparatus strong enough without having such a mass of metals as to communicate heat rapidly to its contents; and, further, the friction of the piston rings and the rubbing surfaces of the valves, piston-rods, &c., is difficult to neutralise, lubrication at excessively low temperatures being troublesome.

How far these difficulties may be overcome on original research remains to be proved; but they have been dealt with to some extent in machinery constructed under my direction for technical purposes, and it may be observed that this machinery differs essentially from apparatus previously used, inasmuch as its construction admits of the liquefied gases being produced in a *continuous stream*, whereas in all former experiments with the liquefaction of gases, a small volume has been first confined and liquefied, the experiment then coming to an abrupt end.

In a paper read to the Chemical Society of London (Sept., 1875) I described the effect of pressure and cold upon the gaseous products of the distillation of carbonaceous shales, which remain permanent after all the condensable vapours within are removed in the usual way by cooling to atmospheric temperature. These gases, whilst being permanent at 50° , yield under the influence of a pressure of about 10 atmospheres and a cold of 200° , large quantities of volatile liquid hydrocarbons, consisting chiefly of butylen, amylen, hydride of amyl, and hexylen.

The machine which is the subject of this paper was designed to deal with 300,000 cubic feet per day of this waste gas, by subjecting it to the cold and pressure just mentioned, and has now been working three years, having liquefied, in round numbers, about a quarter of a million gallons of these liquid hydrocarbons. It involves—

- (1.) The pumping of the gas by steam-power into a system of tubes capable of being externally cooled, and from which condensed liquids can be drawn off by ball-cocks.
- (2.) Employing the compressed gas after being deprived of its liquid for working a second engine coupled with and parallel to the first, thus receiving a portion of the force originally employed in the compression.
- (3.) Employing the expanded gas after having had its temperature reduced in the act of doing the work of pumping for supplying the necessary cold for cooling a portion of the condenser pipes to zero.

The machinery is kept in motion by the piston's cylinders, A and A1, the pistons of which are connected with a common crank shaft, both being of 30-inch stroke.

Between these two motive cylinders is a heavy fly-wheel of about 7 tons weight. It became very evident in the early stages of construction that some kind of automatic regulator would be required, so that the speed of the machine should be such as to exercise no undue suction upon the shale retorts, otherwise atmospheric air might have been taken into the machine in admixture with the hydrocarbon gases. This was accomplished by putting a small gasometer governor between the two motive cylinders just described, and adjusted so delicately that a variation of pressure equivalent to 0.25 would, by a system of levers, actuate a throttle-valve and open or close the admission of steam to the cylinder, and thus regulate the speed of the engine. These levers, when once adjusted, cause the engine to run at full speed of 80 revolutions when the pressure in the retorts rose to 0.75 (or $\frac{3}{4}$) inch, and to run at half speed when the pressure sank to 0.25 inch.

We will now trace the progress of the hydrocarbon gases. They are sucked into two pumps worked by the motive cylinders A and A1, the piston rods of which extend to the two pumps, and are therein compressed to about 8 atmospheres absolute, or a little more than 100 lbs. per square inch above the ordinary atmosphere. Under these circumstances some hundreds of degrees of heat are generated which require to be removed: this is accomplished in great part by injecting about 8 cubic inches of water into each pump every stroke of the engine. This water is forced into the gas-pump by small injection-pumps. The compressed gas is now conveyed by the pipes with injected water to the top of a surface condenser, and passes downwards through 200 iron tubes of about 1 inch diameter and 4 feet 6 inches long, these tubes being surrounded with cold water. The mixture of compressed gas, liquefied hydrocarbons, and injected water arrives at length at about 70° F. in reservoir at bottom of the surface condenser. The water and liquefied hydrocarbons are allowed to escape by an automatic regulated cock, and the compressed air is carried to the top of a second surface condenser, precisely similar in construction and with precisely similar outlets at the bottom reservoirs. It is then carried forward to the top of the third surface condenser, where it first passes downwards through a chamber packed with salt, so as to convert any suspended mixture into brine, and afterwards further downwards through 200 more 1-inch iron pipes in the case *not* surrounded with water. The compressed gas-still of about 8 atmospheres pressure is finally used for working the motive cylinder, which does not differ in construction from a steam cylinder, from which it is discharged after doing work considerably below zero Fahr. This constant stream of ejected and cold gas is made to circulate around the condensing pipes of the third surface condenser, and is finally carried away to be burnt as fuel under the boiler, being chiefly a residue of marsh-gas and hydrogen.

The cycle is thus complete, and it only becomes necessary to indicate all the cylinders and note the volumes and temperatures of the incoming water and gas and their final temperatures to have most interesting proof of some of the most important fundamental laws of thermo-dynamics.

The machine was driven by steam of 50 lbs. initial pressure, and when it became desirable to indicate the cylinders the working pressure was kept as nearly as possible 100 lbs. to the square inch, and the piston speed moderate, viz., 144 feet per minute (48 revolutions). Under these circumstances it was found that the—

Motive cylinder A indicated	33 h.p.
" " A1 "	7 "
Total driving power	40 "
The gas-pumps offered a resistance of	32 "
Difference	8 "

The indicator cards show that the volume of compressed gas introduced into cylinder A1 became reduced to atmospheric pressure by the end of the stroke.

It is admitted to the cylinder not at the full pressure of 100 lbs., but by means of a reducing valve at about 60 lbs., being thus cut off at one fourth of the stroke. The recovered power seems comparatively small, but it must be taken into account that there is some loss of gas during its progress through the machine at the points where the liquid hydrocarbons are drawn off (probably 10 per cent); also, that there will be some of the gas liquefied, and that the residue of hydrogen and marsh-gas, being so very mobile, might have a tendency to pass between the piston block rings and the inside face of the cylinders. Taking these facts into consideration, the working of this cylinder has been very remarkable. It is generally coated externally with some inches thick of ice from the freezing mixture deposited upon it from the external atmosphere.

The indicator cards of the gas-pump are very beautiful, and show a very near approach to the true isothermal curve of compression, resulting from the law of Mariotte. No doubt much of the beauty of this card is owing to the extremely small clearance spaces at the end of the stroke of the pump piston, viz., 0.25 of an inch, which again gets filled up with water from the injecting pumps. Such good curves also demonstrate the efficiency of the injection of the cold water by the small force-pumps, and the superfluity of elaborate arrangements, for throwing in pulverised water—insisted upon by Colladen, of Geneva, and other Continental engineers. This machinery has been frequently run at pressures approaching 150 lbs. to the square inch, and piston speed of 240 feet, without ever causing the pump-barrels or valves to reach a temperature of above blood-heat.

The pump-valves are somewhat peculiar in construction, the arrangement being suggested by my friend, Mr. John Thompson, of Messrs. R. Laidlaw and Sons, the builders of the machine. Each pump end has four suction-valves of 1½ ins. diameter, and three delivery-valves of 1¼ ins. diameter. Each of these valves work in a wrought-iron barrel, which contains the spring and the valve-spindle suitably guided. These wrought-iron barrels containing the valves are about 2¼ ins. diameter, and are externally grooved with a thread, so as to enable them to be screwed into the ends of the pump, or with the whole contents removed at pleasure.

The valves have worked very well, but the springs being light require replacing at frequent intervals. Subsequent experience has certainly induced me to prefer valves fewer in number, and of larger diameter so as to admit of stronger springs, but on the whole the arrangement has been very effective.

The piston blocks of the gas-pumps were originally provided with three-eighths square steel rings, but latterly it has been found that the common ¼-inch square cast-iron ring wears best, and keeps the pumps in good working order for fully six months.

The machine has been working continuously from Monday mornings to the following Saturday night as a rule without stopping, and has not been stopped for overhauling or repairs more frequently than the average of steam-engine machinery.

Passing from mechanical details, as an example of results obtained by the machinery the following summary of consecutive observations made over a period of thirty days at the latter end of 1876 may be stated:—

Average temperature of the gas after being expanded and discharged from the motive cylinder A 1	30° below zero F.
Average temperature of the compressed gas on its way to be expanded after leaving the surface condenser S 3	20° above zero F.
Minimum temperature attained by the gas discharged from the motor cylinder H 1	47° below zero F.

Practical considerations as to wear and tear, steam consumption, &c., made it undesirable at that time to increase the working pressure above 135 lbs. to the square inch,

but there is no doubt even lower temperatures would have resulted if the capabilities of the machine had been stretched to their utmost limit.

The hydrocarbon liquids obtained by this process are those produced by pressure alone escaping from the first and second, and those escaping from the third surface condenser at temperatures approaching zero, the result of combined cold and pressure. The former has generally a specific gravity of 0.710 at 60°, the latter of about 0.670 at 60°. The total produce of condensed hydrocarbons has been about 2000 gallons per week, which, when distilled, yield a considerable percentage of extremely volatile liquid hydrocarbons of specific gravities varying from 640° to 0.660. These liquids, judging from the action of bromine, are chiefly amylene, hexylene, and dissolved butylene, with a small admixture of the corresponding hydrides, whereas the extremely light portion of American petroleum are in main composed of the hydrides of the alcohol radicles.

The machinery I have just described was built for Young's Paraffin Light and Mineral Oil Co., for dealing with a portion of the gas produced at their works, probably about one-fifth. There are some who believe that the ends attained by this machine are as well accomplished by processes dependent upon gaseous absorption, the absorbent liquids being oils of heavy specific gravity; but my object in this paper is not to discuss this question, but to call attention to the process as the first application of Faraday's principle of the liquefaction of gases combined with an application of the principles of the mechanical production of cold, first foreshadowed by Count Rumford and Sir Humphry Davy, and developed by Joule, Clausius, Rankine, and Sir W. Thomson.

IMPROVED METHOD FOR MAKING PLATINUM-ALLOY ASSAYS.

By NELSON W. PERRY, E.M.

ABOUT a year ago I had occasion to make some assays of platinum alloys. The first method employed consisted of cupellation with addition of Ag and Pb, the loss being base metal. The silver was obtained by precipitating from solution in HNO₃ with HCl. This necessitated bringing the precipitate on a filter, washing thoroughly (giving a large filtrate for evaporation), drying, weighing, and calculating the Ag from weight of AgCl obtained. I will not detail this method further, but mention this last step to show one of the tedious steps in the operation. Doubtless many of your readers are familiar with this assay. The results by this method—strange to say, an established one—I found exceedingly unsatisfactory and inaccurate; one of the causes of its inaccuracy being that the percentage of platinum is obtained by difference, namely, all the other constituents being determined, their combined percentage is subtracted from 100. The error is therefore cumulative for platinum. The assay, or rather combined assay and analysis, as it is, required almost as much time as a good quantitative analysis, and yet could lay no claim to equal accuracy.

I therefore set myself to work to devise, if possible, some better method, the results of which I set before you.

In platinum alloys, or native platinum, the metals to be determined are base metal, Ag, Au, Pt, and iridosmine.

Base metal is removed from the others by cupellation. Silver is soluble in H₂SO₄, while the others are untouched.

Platinum when alloyed with twelve times its weight of silver, is soluble in HNO₃.

Gold is soluble in aqua regia, and iridosmine untouched by acids.

Making use of the above properties, I was enabled to effect a separation of the metals both accurately and rapidly, no filtering being required, and all the washing being done by decantation.

Assay of platinum alloys containing base metal, silver, platinum, gold, and iridosmine.

Charge Pt 200 Mg, pure Ag 150 Mg, or sufficient to produce perfect cupellation (exact weight.)

Wrap charge in sheet lead and cupel. Weigh button. Loss = base metal.

Flatten button, anneal, roll out thin, anneal again, and make into cornet as in gold bullion assay. Introduce cornet into parting flask and part with concentrated H_2SO_4 . Wash, anneal, and weigh. Loss from previous weight = Ag in original alloy + Ag added for cupellation.

Alloy cornet with at least twelve times the amount of Ag that there is Pt present, and, as before, form cornet and part first with HNO_3 sp. gr. 1.16, and then HNO_3 sp. gr. 1.26. Wash thoroughly, anneal in annealing cup, and weigh. Loss = Pt.

Treat residue with *aqua regia*, obtain Au by loss—the residue is iridosmine.

Time to complete assay in duplicate, 2 hours 45 minutes.

The quality of Ag added should at least be sufficient, so that after the addition the Ag in the alloy will be to the Au as 3 : 1.

As platinum and iridosmine add greatly to the infusibility of the compound, silver in sufficient quantity must be added to prevent "freezing" and give a perfect cupellation. Any large excess over these requirements is to be avoided—first, because the residue, after parting, will in that case be non-adherent and in a more or less fine state of subdivision, which may occasion loss in washing by decantation; second, the larger the button cupelled the more difficult it is to obtain a good cupellation, and the greater the loss of Ag during the process. It may, for this reason, sometimes be necessary to use only 100 Mg of the alloy for assay instead of 200 Mg, as above.

The cupellation should take place at a moderate temperature, until near the "blick," when the assay should be thrust back into the hottest part of the furnace to prevent "freezing." The button must remain in the muffle until all the Pb is gone.

In parting with H_2SO_4 , boil for several minutes. In other respects, this operation is identical with the gold-bullion assay. Any large excess of Ag over twelve times the amount of Pt in alloy is to be avoided, as it causes the residue, after parting, to be too fine and float, thereby occasioning loss in washing. Insufficient Ag is even worse, as the Pt will then be only incompletely dissolved.

By the above method I was successful in obtaining very closely duplicating results, was enabled to do away with all precipitation and filtering, no apparatus being required, except that necessary for the gold and silver bullion assay, and, what is only second in importance to accuracy, attained results with the least expenditure of time. Mr. William Strieby, A.M., E.M., has assisted me materially in perfecting this assay, and employed it in his own work with equally satisfactory results.

I present the above to your readers, hoping it may prove of service to some engaged in similar work.—*Engineering and Mining Journal*.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, February 20, 1879.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

AFTER the confirmation of minutes, &c., the following certificates were read for the first time:—W. North, F. Podmore, W. Y. Gent, W. Radford.

The list of Officers for the ensuing year as proposed by the Council was then read —

President—Warren de la Rue, F.R.S.

Vice-Presidents—The list remains unaltered with the insertion of J. H. Gladstone and omission of Warren de la Rue.

Treasurer—W. J. Russell.

Secretaries—W. H. Perkin, H. E. Armstrong.

Foreign Secretary—Hugo Müller.

Other Members of the Council—M. Carteghe, A. H. Church, W. N. Hartley, C. W. Heaton, E. Riley, W. Chandler Roberts, T. E. Thorpe, W. Thorp, J. L. W. Thudichum, W. A. Tilden, R. V. Tuson, R. Warrington.

The following gentlemen were elected auditors for the year:—R. J. Friswell, J. Spiller, and J. M. Thomson.

The PRESIDENT then called on Dr. OTTO N. WITT to read a paper "On Colouring Matters Derived from Diazo-compounds." During the last three or four years aniline colours have come into such general use as to, in many instances, replace the old costly artificial and natural dyes. Although there has been known for some time a great variety of magenta, violet, and blue aniline dyes, green and yellow dyes were almost unknown until quite recently. Three years ago the author, in a paper read before the Society, indicated a theory as to the relation between the chemical constitution and the colouring power of aromatic substances. In this paper he pointed out that there existed a series of compounds, the colour of which was in close relation to their chemical constitution. The first link of this series is azo-benzene, $C_6H_5-N=N-C_6H_5$. This substance is of a deep yellow colour, but being devoid of salt forming groups is not applicable for dyeing. By introducing amido- or oxy-groups, compounds can be formed having strong affinities for textile fibres, which increase with the addition of each salt-forming group into the molecule. At the time this paper was read amido-azo-benzene and tri-amido-azo-benzene were the only dyes of this class known; the first was of a beautiful bright yellow colour, but fugitive; the second was fast, but dull. Since that time the intermediate di-amido-azo-benzene has been formed and named chrysoidin, which combines the beauty of the monamido- and the fastness of the tri-amido-bodies. The preparation of chrysoidin is then given. Griess has shown that not only can amido-azo-compounds be obtained, but that the oxy-derivatives of azo-benzene and other similar bodies can be prepared by the action of diazo-compounds on the corresponding phenols; these oxy-derivatives are also dyes; so that these di-azo-compounds have opened out an almost inexhaustible mine of new and beautiful dyes. Since Hofmann's paper on chrysoidin investigations on this class of compounds have been set on foot in the laboratories of almost all aniline colour manufacturers. The patents taken out for their production are constantly increasing in number. In consequence of his connection with Messrs. Williams, Thomas, and Dower the author has not been able to carry out his original intention of describing fully the preparation and properties of all his new azo-colours. The prototype of these compounds is chrysoidin. The author has already given a description of the properties of this substance in *Journ. Chem. Soc.*, ii., 457, 1877. He has since prepared in a pure state the following analogous substances closely resembling the typical product:—Ortho-tolyl-phenylen-chrysoidin, para-tolyl-phenylen-chrysoidin, phenyl-toluylen-chrysoidin, ortho-toluylen-chrysoidin, para-tolyl-toluylen-chrysoidin, phenyl-toluylen-chrysoidin sulphonic acid, α -naphthyl-phenylen-chrysoidin sulphonic acid, α -naphthyl-toluylen-chrysoidin sulphonic acid. Each basic colour has an acid counterpart similar in shade and constitution but containing hydroxyl- in place of amido-groups. The acid counterpart of chrysoidin has been prepared by Baeyer and Fägar, and studied by Typke. This compound is a beautiful but unstable dye. The author therefore introduced a sulpho-group into its molecule by treating resorcin with para-di-azo-benzene sulphonic acid. The substance has since been described by Griess. Its constitution that meta-di-azo-oxy-benzene sulphonic

acid. Its acid sodium salt is sold under the name of tropæolin O. By a similar reaction monoxo-azo-benzene sulphonic acid has been obtained from phenol. Its sodium salt is known as tropæolin Y. Tropæolin OOO No. 1 is oxy- α -naphthyl, and tropæolin OOO No. 2 the sodium salt of oxy- β -naphthyl-azo-phenyl sulphonic acid. Tropæolin OOOO is isomeric with tropæolin OOO Nos. 1 and 2. Another class of azo-colours can be obtained if the salt-forming properties of amido-azo-benzene and analogous compounds be intensified by introducing one or more sulpho-groups. Thus, by acting with para-di-azo-benzene sulphonic acid on dimethyl-anilin, a dye is obtained, in which, however, the basic properties are too prominent, and to obtain a proper equilibrium one phenyl instead of two methyl groups must be introduced into the molecule of amido-azo-benzene sulphonic acid. Thus is produced one of the most beautiful of the azo-colouring matters. It is known as tropæolin OO. The author gives a detailed description of the preparation and purification of phenyl-amido-azo-benzene, which, when pure, forms leaflets or needles of a fine golden yellow colour; M.P. 82° ; soluble in benzolin, alcohol, ether, and benzene. The author reserves for a future communication a description of amido-diphenyl-amin. Phenyl-amido-azo-benzene when treated with amyllic nitrite and acetic acid yields a nitrosamin crystallising in orange needles, melting at 119.5° ; its formula is $C_{18}H_{14}N_4O$. By the action of di-azo-benzene-sulphonic acid on diphenyl amin, tropæolin OO is obtained. It is a powerful acid and forms well-defined salts. The author gives a description of the potassium, sodium, ammonium, trimethylamin, barium, calcium, and aniline salts. In conclusion the author trusts that he has succeeded in giving a sketch of what may be called the genuine azo-colours, the true oxy- and amido-derivatives of azo-benzene, and analogous compounds. Compounds derived from amido-azo-bodies by the action of amines as well as coloured substances containing the azo-group, $-N=N-$, may also be termed azo-colours. The author hopes in a future paper to lay before the Society his researches on these more intricate compounds.

The PRESIDENT said that all must have appreciated the very lucid and brief manner in which Dr. Witt had described this beautiful series of compounds, interesting both from a scientific point of view and from their application as dyes.

Mr. PERKIN said that the paper was of peculiar interest to him, as showing the enormous strides which aniline dyestuffs had taken during the last few years. He would like to ask whether these dyes were suitable for silk, wool, and cotton?

Dr. ARMSTRONG remarked that the brief description given by Dr. Witt conveyed but a slight notion of the enormous amount of work concentrated in the results. He would ask Dr. Witt if he could point out the influence of the different groups in modifying colour? and also if he had any experience of tropæolin OO as an indicator in alkalimetry?

Dr. WITT said that most of the dyes, especially the sulpho-compounds, were only suitable for silk and wool, the amine compounds dyed cotton. He had already pointed out two groups concerned in the tinctorial power of a substance, which he had called chromogens and chromophors (*Chem. Journ. Soc.*, ii., 403, 1876). Subsequent results had confirmed these conclusions. Oxy- and amido-groups principally had to do with the colour of the dyestuff. The sulpho-group weakened the colour but conferred stability on it. Also, *ceteris paribus*, the more oxy- or amido-groups contained the more powerful is the dye. It does not follow, however, that the beauty of the colour increases with its intensity. The heavier the molecule the more the colour tends to the violet end of the spectrum. Some importance must be attached to the localisation of the salt-forming groups, i.e., the nearer they are together in the molecule the more powerful is the colour. Tropæolin OO has been recommended as an indicator by Von Mütler. It is not affected by CO_2 , and only after

some time by SH_2 , so that it can be used to titrate crude soda. A still better indicator is the dimethyl-diazo-benzene sulphionate of ammonium.

Dr. RUSSELL then took the chair during the reading of a paper by Dr. GLADSTONE entitled, "*Investigations into the Action of Substances in the Nascent and Occluded Conditions (Hydrogen, continued)*," by J. H. GLADSTONE and A. TRIBE. From a recent study of the behaviour of nascent and occluded hydrogen (*Chem. Soc. Journ.*, 305, 1878) the authors concluded that these conditions of the element are not, as hitherto supposed, different, but are closely related if not identical, and that the activity of the so-called nascent hydrogen is the consequence of its intimate association with the metals employed to bring about the liberation of the element. In the present paper the authors have examined the action of nascent and occluded hydrogen on nitric and sulphuric acids. The nascent hydrogen was obtained by electrolytic decomposition of the acids in Hofmann's arrangement for illustrating the composition of water electrolytically. Nascent Hydrogen and Nitric Acid:—Faraday and Bourgoine have shown that electrolytic hydrogen reduces strong nitric acid, but only imperfectly or not at all when diluted with an equal bulk or more of water. If the oxidation of the freed hydrogen in this action results from its being in the occluded condition, the reduction of the acid would depend on its strength only in so far as this facilitated the de-occlusion of the hydrogenised electrode, and the stronger acid might be expected to do this the more readily. And it follows that with a given strength of acid the amount of free gaseous hydrogen should bear some relation to the rate at which the electrolysis takes place, for were the gas freed from its nitric radical, not faster than it could be occluded, none should pass through the liquid; but if the evolution of the gas were faster than the occlusion, free hydrogen should escape. The authors have proved that this is the case. Their results are given in the annexed table—

Grove's Cells Used.	Proportion of Acid to Water.	Time of Experiment.	Reduction in c.c. of Oxygen.	Free H.
1	1 acid	3 hours	31.5	0
2	68.2	55 mins.	28.4	0
4	per cent	22 "	28.8	0
8	0 water	10 "	29.4	0
1	1 acid	215 "	30.6	0
2	to	42 "	29.0	2 c.c.
4	1 water	19 "	24.2	9 "
8		8 "	16.8	22 "
2	1 acid	61 "	17.0	30 "
4	to	18 "	0.5	65.7
8	2 water	8 "	0.3	68.7

Each experiment went on till 35 cc. of oxygen collected at the anode. In the 2nd, 3rd, and 4th experiments of the series 1 to 1 the evolution of hydrogen at the cathode ceased quite suddenly at the end of three minutes. This is due to the presence of nitrous acid, which prevents the escape of hydrogen with eight cells when present in the proportion of 0.059 grm. to 100 cc. of 1 to 1 acid. Occluded Hydrogen and Nitric Acid:—Nothing is known as to the action of occluded hydrogen on nitric acid. Dr. Armstrong infers (*Chem. Soc. Journ.*, 1877, 82) that it has no action. The authors charged some finely-divided platinum with hydrogen. On pouring on it some pure nitric acid the metal became red-hot, the liquid became yellow, and nitrous fumes escaped; so that occluded as well as nascent hydrogen acts on nitric acid. Palladium charged with hydrogen dissolves in nitric acid 1 to 1 without setting free any gas, so that the hydrogen in this case must be oxidised. Nascent Hydrogen and Sulphuric Acid:—The acid was decomposed electrolytically. The authors conclude that hydrogen associated with platinum reduces oil of vitriol very readily, sulphurous acid being sometimes formed; a film of sulphur also appears on the negative electrode. Occluded Hydrogen and Sulphuric

Acid:—Finely divided platinum did not reduce the acid, but the metal charged with hydrogen immediately gave the odour of sulphurous acid when the sulphuric acid was poured on it. Platinum charged with hydrogen also reduces sulphuric acid. In conclusion, the authors give the results of some experiments made by plunging a small piece of sheet magnesium into an excess of strong nitric acid diluted with an equal bulk of water. The metal dissolved in one or two seconds, gas being given off which was combustible and explosive and contained hydrogen. The authors claim to have demonstrated the possibility of the replacement of hydrogen in nitric acid by a metal, and to have established the close likeness of character, and therefore of condition, between the so-called nascent hydrogen and the hydrogen occluded by metals.

Dr. ARMSTRONG said that he had not stated in the paper referred to by Dr. Gladstone that occluded hydrogen had no action on nitric acid, but had asked the question has occluded hydrogen, &c.? He had dissolved some pure nickel, given to him by Dr. Russell, in nitric acid and obtained hydrogen, whereas crude nickel gave none. He therefore concluded that the pure nickel might contain some occluded hydrogen. Though admitting the extreme value of the authors experiments, he did not quite agree with all their conclusions.

Dr. RUSSELL said that he had heated and pumped the nickel referred to repeatedly, but had never succeeded in obtaining any hydrogen.

Dr. WRIGHT suggested that the metal might contain a trace of oxide, and when heated, the hydrogen would be converted into steam.

Dr. GLADSTONE briefly replied and then took the chair.

Mr. J. T. BROWN then read a short paper "*On some Methods of Vapour-Density Determinations.*" The author criticises the methods and especially the formulæ of Hofmann, Wertheim, W. M. Watts, Goldschmidt, Freichs, and Meyer. As the actual tensions of the vapour of mercury under various conditions are not known the author suggests that they might be determined by estimating the vapour-tension of a substance over Wood's metal and mercury at different temperatures. He offers the suggestion in the hope that some one will take up the subject. Wood's metal is a fusible alloy, composed of Bi₁₅, Pb₈ Sn₄ Cd₃.

Drs. WITT and ARMSTRONG pointed out that the new method suggested by Meyer was almost perfect, as exact results could be obtained by it with facility.

The SECRETARY then read a paper "*On the Decomposition-Products of Quinine and the Allied Alkaloids.*" by J. J. DOBBIE and W. RAMSAY. In a previous paper the authors gave the results of their experiments on the oxidation of quinine by permanganate. In the present paper the authors have extended their investigation to the oxidation-products of quinidin, cinchonin, and cinchonidin. All these bodies yield, by oxidation with permanganate, acids which are physically and chemically identical. This acid, the authors prove by analysis, &c., to be tricarbo-pyridenic acid. They give in detail the method employed. More than 10 per cent of the acid was obtained from each base. The paper contains an account of the properties and form of crystallisation of the acid, with many analyses. The acid is tribasic. Potash, soda, ammonia, silver, calcium, barium, strontium, zinc, and copper salts were prepared, and are described. The formula deduced from the analysis of the acid and its salt is $C_8H_5NO_6 + 1\frac{1}{2}H_2O$. The result of the present investigations confirms the conclusions previously arrived at by the authors, viz., that there is a close relation between the cinchona bark alkaloids and the bases of the pyridin series, and proves that the four principal alkaloids derived from the cinchona bark all yield on oxidation the same acid. In conclusion the authors draw attention to the fact that their first paper was published March, 1878, and that in the *Ber. der Deut. Chem. Gesell.*, Feb. 11, 1879, is a paper by Hoogeweff and Von Dorp, which confirms the authors researches as regards quinine.

The Society then adjourned to March 6, when the following papers will be read:—"The Quantitative Blowpipe Assay of Mercury," by G. Attwood; "On Gas Analysis and Gas Apparatus," by J. W. Thomas; "The Isomeric Dinaphthyls," by Watson Smith; "On the Action of Isomorphous Salts in Exciting the Crystallisation of Super-saturated Solutions of each other," by J. M. Thomson.

PHYSICAL SOCIETY.

Ordinary Meeting, February 22, 1879.

Prof. W. G. ADAMS, President, in the Chair.

New Members:—Rev. Coutts Trotter, Prof. G. D. Liveing, J. C. Adams, F. W. Paterson.

Dr. C. SIEMENS described his New Electric Current Regulator. A necessary condition of the transmission of power to a distance by electricity along a single conductor and re-distributing it by means of branch circuits to separate electric lamps or motors, is that the current strength in each lamp shall be practically uniform; otherwise the current flowing in the whole branch. Hence the necessity of a regulator to regulate the flow of current so as to keep it uniform, however the resistance of the circuit, or the electromotive force of the source, may vary. The author believes that by properly arranging a number of dynamo-electric machines, either in series or parallel (for intensity or quantity), at each end of the wire, a vast amount of power may be sent along a small copper conductor successfully, provided the distribution is properly regulated. He has designed a regulator based on the heating of a wire by the passage of a current through it. A fine strip of mild steel $\frac{1}{16}$ m.m. thick is stretched horizontally between two terminals. An upright spindle is supported by means of an insulating foot upon the middle of this strip in such a manner that as the strip bends or sags by its expansion, the spindle sinks with it. Now this spindle carries at its top a table or plate of metal (or, as the case may be, a set of radial springs), and as the spindle rises or sinks to different heights this plate or these springs make contact with other springs set radially round; and these contacts take out from or throw in resistance coils into the circuit of the current. The sensitive strip is so thin that it may be regarded as a radiating surface merely, and it may be assumed that its temperature, due to heating by the current, balances itself with the radiation instantaneously. After passing through the steel strip the current flows through the coils thrown into circuit, and, by the arrangement we have described, if the current increase so as to overheat the strip, the latter sags a little more, the spindle sinks, and the consequence is that one or more of the spring contacts is broken, and one or more coils inserted in circuit. A rise of 1° F. in the temperature of the strip is sufficient to liberate two or three of these coils. The fact that the temperature of the strip varies as the square of the current favours the sensibility of the apparatus. An older form of this apparatus having pendulous contacts was also shown; also a regulator in which the expansion by heating of a sensitive wire caused the resistance of several carbon buttons in contact to vary through the pressure exerted on them by means of a bell cranks lever. Dr. Siemens had not been able to prepare carbons which gave the wide variations of resistance obtained by Mr. Edison. Siemens's regulator can also be used as a current meter by causing the sensitive strip to actuate a lever, carrying at its end a pencil writing on a moving paper.

Dr. COFFIN said that he had thought of a regulator in which the heating of a wire spiral in a gaseous chamber would cause the gas to expand and drive up a mercury column past a series of contacts, which would throw resistances in circuit.

Dr. GUTHRIE suspected from some experiments of his

that the conductivity of metals was not strictly proportional to their sectional area.

Dr. SCHUSTER then gave the results of some observations of his on the Spectrum of Lightning. These were made by a spectroscope with two prisms, one for the red and the other for the blue end of the spectrum, which were shifted into the line of sight by a chamber arrangement. Three observations were made, one at Las Ammas, one at Maniton, and one at Salt Lake City, last year. These showed the three nitrogen lines, with three well-defined bands, and one doubtful band. The nitrogen lines correspond to the spectrum of air, and the bands appear to Dr. Schuster to agree with the spectrum of the light round the negative pole of the spark in a tube containing oxygen with adulteration of carbonic oxide.

Prof. AYRTON then exhibited an Exisothermal Model of a Cooling Globe. If we imagine a globe initially heated throughout to a uniform temperature (as was probably the earth), and then kept in a space having a constant temperature but much lower than that to which the globe was heated, then the temperature at every point of the ball will fall, but at very different rates, the parts for example near the surface cooling comparatively rapidly, while those near the centre will cool very slowly. A surface could, therefore, be constructed, such that the x of any point on this surface represented its distance from the centre of the globe, the y the time t from the commencement of the cooling, and the z the temperature of that point at that moment. The nature of this surface would depend on the size of the globe, on the specific heat, conductivity, and surface emissivity of the material. Now the "Experiments on the Heat Conductivity in Stone" of Profs. Ayrton and Perry, described in the *Philosophical Magazine* for April, 1878, enables them to determine these constants accurately for a trachyte sphere, and by using these data they have been enabled subsequently to construct such a surface called by them an "exisothermal" one for a trachyte globe of 8000 miles in diameter, and which gives graphically the temperature of every single point of the earth from the moment when it was at the temperature of molten trachyte down to eight hundred thousand million years afterwards, that is, until long after the present era.

OBITUARY.

PETER LE NEVE FOSTER, M.A.

THE Society of Arts has just sustained a severe and sudden loss by the death of its well-known Secretary, Mr. Peter Le Neve Foster. On Thursday, February 20, immediately on his return to his own house at Wandsworth, Mr. Foster was seized with a sudden attack of heart disease, and some of his family coming into the room, where he had been sitting by himself for a few minutes reading the newspaper, found that he had fallen back from his chair, dead. So little expected was the illness that he had finished his ordinary day's work at his office, and had even walked up from the railway station to his own house.

Mr. Foster was born August 17, 1809, and was the son of Mr. Peter Le Neve Foster, of Lenwade, Norfolk. He was educated under Dr. Valpy, at the Norwich Grammar School, from whence he went up to Trinity Hall, Cambridge. After having taken his degree as Thirty-eighth Wrangler in the Mathematical Tripos of 1830 he was elected Fellow of his College. He was called to the Bar at the Middle Temple in 1836, and practised as a Conveyancer till he became Secretary to the Society of Arts in 1853.

Mr. Foster was intimately associated with all the earlier great exhibitions. He was appointed to carry into effect the provisions of the Act for the Protection of

Inventions in the Exhibition of 1851, and was also named Treasurer for payment of all executive expenses in the original Commission. During his term of office the Society of Arts has flourished as it never previously did, and owing in no small degree to his exertions it has quadrupled its number of members and increased its resources in a still greater proportion. Much of its work was originated by the late Secretary, and all of it was carried out by him.

From his boyhood upwards Mr. Foster took a keen and enlightened interest in many branches of science. He was one of the first to take up and practice, as a scientific amateur, the art of photography, and on this subject he has written a good deal in the pages of the *Photographic* and other periodicals. He was one of the Founders of the Photographic Society, and was on its Council for many years. He was President of the Quekett Microscopical Club for a year, and also served for some time on the Council of the British Association, the meetings of which he has attended regularly for the past twenty years. For many years he acted as Secretary of the Mechanical Section of the Association. He read several papers before the Society of Arts, and was, of course, a constant contributor to its *Journal*, the whole series of which, from the middle of the first volume, was published under his direction.

Mr. Foster leaves behind him a very numerous body of friends, to all of whom his genial and kindly character had endeared him. On the occasion of his completion of twenty-five years' service as Secretary, a strong committee was formed to present Mr. Foster with a testimonial. The list for this was just about to be closed, the amount subscribed being over £1200. Under present circumstances it is probable that a fresh effort will be made to increase this amount, so that a fitting memorial may be presented to Mrs. Foster.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale.

No. 60, December, 1878.

Report Presented by M. Personne on the Process of MM. Lecourt and Guillemare for Using Chlorophyll in Place of the Copper Salts Employed in the Preparation of Preserved Fruits, Green Vegetables &c.—The patentees find that if the vegetable fibre is placed in contact with soluble chlorophyll it becomes saturated with the colour at about 100°.

Crystallisation of Sugar and the Manufacture of Sugar-candy.—G. Flourens.—A lengthy paper not adapted for useful abstraction.

Biedermann's Central-blatt.

Heft 1, January, 1879.

Comparative Observations of Rain-fall According to Fautrat's Method.—A. Johnen.—The author found the quantity of rain in a beech-wood 13 per cent greater than in the open country. In a pine-wood the excess was only 2 per cent.

Cohesive Power of Various Kinds of Soil.—Prof. F. Haberlandt.—The author moistened different kinds of earth with water, moulded them into cylinders of equal size, and ascertained their "breaking weight" in the usual manner. The cohesive power is affected chiefly by its mechanical structure, not by its degree of fineness.

Every soil has at some degree of moisture a minimum cohesive power.

Heat-capacity of the Constituents of Soils.—Dr. C. Lang.—The specific heat of the several constituents of soils differs much less if referred to volume than to weight.

Manure Experiments on the Agricultural Trial-field of the University of Giessen.—Prof. A. Thaer.—The quantity of nitrogen given to a selected "morgen" of land in the form of manures during seven years amounted to 89.5 lbs. The crops reaped during the same years contained together 198.69 lbs. of nitrogen. Consequently the soil had given 109.19 lbs. nitrogen more than it had received. Hence, whilst the manures furnished 45 per cent of the nitrogen in the crops, the atmosphere had yielded 55 per cent.

Trade Cattle Foods.—Dr. E. Wein, Prof. J. Nessler, Prof. A. Mayer, and Prof. R. Heinrichs.—According to the above chemists the composition of an English cattle food is—

	Wein.	Nessler.	Mayer.
Moisture	13.72	—	12.9
Albuminoids	11.75	13.21	9.4
Oily matter	4.28	4.24	3.6
Non-arotised extractive ..	67.24	—	66.9
Vegetable fibre			3.6
Ash	3.01	—	3.6

Wein and Mayer, from chemical and microscopical evidence, conclude that the food is composed of equal parts of bruised maize and locust-beans, and that the essential oil of a plant of the umbelliferous order has been added. Another English cattle food in the form of cake contained also a large proportion of locust-beans.

Fustus Liebig's Annalen der Chemie,
Band 194, Heft 2 and 3.

Synthesis of Tin-phenyl-compounds.—Dr. B. Aronheim.—This paper contains an account of tin-phenyl-chloride and of its derivatives tin-diphenyl-hydroxyl-chloride, tin-phenyl-oxide, tin-phenyl-dichloride, tin-phenyl-chloro-bromide, tin-phenyl-chloro-iodide, tin-phenyl-dibromide, and of the action of sodium ethylate upon tin-diphenyl-dichloride and the formation of tin-triphenyl-chloride by the action of sodium amalgam or of ammoniacal gas upon tin-phenyl-chloride.

Studies on Phosphates.—E. Erlenmeyer.—A very detailed account of mono-ferro-phosphate, including its behaviour with water and alcohol; of mono-ferri-phosphate, of mono-diferri-phosphate, di-ferri-phosphate, tri-ferri-phosphate, mono-aluminium-phosphate, and tri-aluminium-phosphate.

Contributions to the History of the Naphthalin Series.—J. Stenhouse and C. E. Groves.—The authors describe β -naphtho-quinon, nitro- β -naphtho-quinon, dinaphthyl-diquinhydrin, dinaphthyl-diquinon, dinaphthyl-diquinol, and dinaphthyl-diquinhydrin. The authors have observed that benzo-quinon and α -naphtho-quinon yield diquinons and diquinols on condensation.

Action of Potassic Bibromate with Sulphuric Acid upon Cholic Acid.—Dr. H. Tappeiner.—The products obtained are cholesteric acid, stearic acid, lauric acid, and cholic acid, which are here successively described together with certain of their derivatives.

On Triphenyl-methan and Rosanilin.—E. and O. Fischer.—This valuable treatise is unfortunately not susceptible of useful abstraction.

MISCELLANEOUS.

Gossip in the Provinces.—(From a Correspondent).—The subject of the greatest interest for chemists just now is the new phase of the water-analysis question. Dr. Tidy's paper, read before the Chemical Society, is generally

regarded as a very valuable contribution, containing as it does the results of years of work, and affording chemists another factor of value for judging of the character of drinking-water. There seems indeed too much tendency on the part of the adherents of one or the other system of water-analysis to swear by that method which they are accustomed to use and to pooh-pooh all others as unreliable. Thus Dr. Frankland appears to suppose that chemists who use any other method than his own do so to avoid the trouble of determining the organic carbon and nitrogen. As pointed out by Dr. Dupré, this assumption is unwarrantable, though certainly the facility with which a process may be carried out is an important consideration when there is a choice of alternative methods. There is, however, a very widely spread feeling among chemists that Dr. Frankland has never sufficiently met Mr. Wanklyn's objection respecting the action of nitrates on readily decomposable organic matter. It is clearly not an answer to this objection to quote the figures obtained by the analysis of sulphate of quinine, either in presence or absence of nitrates, though we are unable to recall any experiments to ascertain the effect of the presence of a large excess of nitrates on the determination of the nitrogen of carbon of even such a stable body as the sulphate of quinine.

Dr. Tidy did good work by protesting against the attempt to reduce water-analysis to the empirical application of a few simple tests. On the contrary, the more data the chemist has on which to base his opinion the more correct that opinion is likely to be.

We fear that Mr. Wanklyn has done extensive harm by not sufficiently insisting on the consideration of the supplementary data, and by teaching chemists of limited experience and knowledge of the science to rely too implicitly on the indications given by the ammonia process. We know of chemists who restrict their examination of drinking-waters solely to the ammonia process, and do not even supplement it by a determination of the chlorine and total solids as recommended by Mr. Wanklyn. There is also a widespread habit of ignoring the nitrates and nitrites on the ground that when the oxidation has reached that stage no objectionable impurity can remain. Those who argue thus must be ignorant of the extreme readiness with which ammonia undergoes oxidation in a porous soil, whilst a change of weather, by choking the pores of the soil, will cause a water which previously contained nitrates and no ammonia to present the strongest evidences of the presence of unoxidised sewage.

Respecting the determination of the organic nitrogen of carbon of drinking-water, it is interesting to note that distinct advance has been made towards ready means of obtaining these data. Thus Dittmar has shown that accurate determinations of the nitrogen could be obtained by igniting the residue with soda and baryta—not with soda-lime, as stated by Mr. Hartley—and Dupré has quite recently described an easy method of estimating minute quantities of carbon. If these methods bear rigid examination there is a future for the disciples of Dr. Frankland that is very hopeful.

What have chemists been about all these years that they leave it for a metal-broker to utilise the Bessemer process for treating sulphides? Mr. Hollway's paper at the Society of Arts fairly takes our breath away. Fancy blowing a stream of air through molten sulphide of iron for ten consecutive hours, and keeping up the temperature merely by the addition of lumps of raw pyrites. Mr. Hollway appears to have no difficulty in keeping up the temperature, but whether he will succeed in obtaining a fairly rich regulus without material loss of copper in the slag and by volatilisation is another question. One of the most curious points about the process is that more than half the sulphur appears to be liberated in a free state. As pyrites has always hitherto been treated in close vessels at comparatively low temperatures it may very possibly be that a different reaction occurs at a white heat. At any rate the analyses made seem to show that in the regulus

obtained there is often much less sulphur than corresponds to the formula FeS —a fact that points to the existence of a lower sulphide of iron than any hitherto recognised.

The arguments which Mr. Lockyer has laid before chemists in support of his ideas respecting the dissociation of the elements, though ingenious and dealing with highly interesting and suggestive facts, have produced some feeling of disappointment. The definite and somewhat sensational reports which appeared in some of the daily papers had prepared chemists for facts more tangible than those ultimately adduced in support of the theory. Still Mr. Lockyer has got hold of a good idea, and one which will be certain to repay further investigation. Chemists will look forward to future accounts of his progress.

Does Mr. Lockyer know that the identity of many of the chemical elements can be demonstrated mathematically? The following instance, proving the identity of chlorine and hydrogen is, we believe, due to Prof. Clifford, and affords a good illustration of the way in which chemists misapply algebraic symbols:—

Then, extracting the square root from each side of the equation—

and

MEETINGS FOR THE WEEK.

- MONDAY, 3rd.**—Medical, 8.
— Society of Arts, 8. "Dwelling Houses: Their Sanitary Construction and Arrangements," by Dr. W. H. Corfield, M.A. (Cantor Lectures.)
— London Institution, 7.
— Royal Institution, 3. General Monthly Meeting.
TUESDAY, 4th.—Civil Engineers, 8.
— Royal Institution, 3. "Animal Development," Prof. Schäfer.
— Zoological, 8.30.
WEDNESDAY, 5th.—Society of Arts, 8. "The Social Necessity for Popular and Practical Teaching of Sanitary Science," by Joseph J. Pope, M.R.C.S., L.S.A. Pharmaceutical, 8.
THURSDAY, 6th.—Royal, 8.30.
— Royal Institution, 3. "Sound," Prof. Tyndall.
— Royal Society Club, 6.30.
— Chemical, 8. "The Quantitative Blowpipe Assay of Mercury," by G. Attwood. "On Gas Analysis and Gas Apparatus," by J. W. Thomas. "The Isomeric Dinaphthyls," by Watson Smith. "On the Action of Isomorphous Salts in Exciting the Crystallisation of Supersaturated Solutions of Each Other," by J. M. Thomson.
FRIDAY, 7th.—Royal Institution, 9. "Sensation," by Prof. Huxley.
— Geologists' Association, 8.
— Society of Arts, 8. "The Plants of India Adapted for Commercial Purposes," by John R. Jackson.
SATURDAY, 8th.—Royal Institution, 3. "Colbert and Richelieu," by Mr. Walter H. Pollock.
— Physical, 3. "On a New Theory of Terrestrial Magnetism," by Prof. Ayrton and Perry. "On some Experiments with the Quadrant Electrometer," by Dr. J. Hopkinson. "On the Maintenance of Constant Temperatures and Pressures," by F. D. Brown.

TO CORRESPONDENTS.

ERRATUM.—P. 67, col. 2, line 12 from top. The words "I am told the substance was not quite pure" applies only to the chrysene. The dinaphthyl was beautifully white and absolutely pure.

W. E. Robinson and Co.—You had better advertise for a market in our columns. There are plenty of uses for the salt.

J. G. H.—We regret we cannot give the desired information. Our correspondent had better advertise in the *CHEMICAL NEWS*.

CULLEY'S PRACTICAL TELEGRAPHY.
In One Volume, 8vo., with 132 Woodcuts and 18 Lithographic Plates of Machinery and Apparatus, Price 16s.

A HANDBOOK OF PRACTICAL TELEGRAPHY. By R. S. CULLEY, Member Inst. C.E. (Adopted by the Post Office and by the Department of Telegraphs for India.) The Seventh Edition, thoroughly revised and enlarged.
London: LONGMANS and CO.

WATTS'S DICTIONARY OF CHEMISTRY.

Seven Volumes, 8vo., price £10 16s. 6d.

A DICTIONARY OF CHEMISTRY, and the Allied Branches of other Sciences; founded on that of the late Dr. Ure. By HENRY WATTS, B.A., F.R.S.; assisted by eminent Scientific and Practical Chemists.

"The English language is not rich in lexicons of science. We would point to this work as a model upon which others might be framed. To the practical analyst this work must prove of the utmost value—to the philosophical investigator it must, as the record of all former labours, be a great gain—and to the student who is true to his studies, it will prove an ever-ready guide. Our manufacturers know the value of chemistry, and are many of them experts in the special branches of the science which bear on their particular industries. They require to know the latest discoveries, and to keep them as it were in stock until the march of improvement renders it necessary to apply them. This 'Dictionary' places them in possession of these desiderata."—*Athenæum*.

THIRD SUPPLEMENTARY VOLUME

(VOL. VIII.), completing the Record of Chemical Discovery to the year 1877. In Two Parts, of which the First is now ready, pp. 844, price 36s. cloth.—Part II. in the Autumn.

"We cannot give this volume greater praise than by saying that it is worthy of the European reputation which Mr. Watts's 'Dictionary' has already acquired as a standard work of reference."—*Bristol Mercury*.

London: LONGMANS and CO.

COMPLETION OF THE SEVENTH EDITION.

Complete in Four Volumes, with 2500 Woodcuts, price £7 7s. cloth or £8 16s. half-bound in russet.

URE'S DICTIONARY OF ARTS, MANUFACTURES, and MINES,

containing a Clear Exposition of their Principles and Practice. The Seventh Edition, re-written and enlarged. Edited by ROBERT HUNT, F.R.S., Keeper of Mining Records; assisted by numerous Contributors eminent in Science and familiar with Manufactures.

* Also VOL. IV. separately, completing the work to the present time, 8vo. with 440 Woodcuts, price 42s.

London: LONGMANS and CO.

A Technical Laboratory in London (speciality

Coal-tar Products, Aniline Dyes, Anthracene, Artificial Alizarin) is open to receive two or three more Pupils for training in the technical and industrial pursuits.—Apply to Mr. 305, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

A Chemist of Nine Years' standing, with ex-

tensive experience in all branches of the Science, and who has devoted special attention to oils and fats, will be open to an Engagement in April. Highest references.—Address, A., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

A Gentleman of business habits, with a good

knowledge of practical chemistry, and well acquainted with several foreign countries, is desirous of an Engagement as Manager, with the view of becoming an active partner, in some well-established sound chemical works manufacturing acids, artificial manure, or aniline colours, and situated in or close to London. Highest references. Communications of principals or their solicitors only to be addressed to G. H., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Young Man, at present engaged in a Tar

Work in Scotland, thoroughly experienced in manufacturing liquid ammonia, also sulphate of ammonia from gas liquor, and in refining of benzole and naphthas; with a knowledge of chemistry, German, and French, wishes to improve his position.—Address, S.H., Craigie Chemical Works, Paisley.

Wanted, an Engagement as Junior Labora-

tory Assistant with a firm of Analysts or an Analytical Chemist. Has studied synthesis and analysis for two years. Salary not so much an object as advancement. Highest references, &c.—Address, E. A., Reilly, 17, Bloomsbury Square, W.C.

Wanted, a Laboratory Man.—Apply person-

ally, between 2 and 4 p.m., or by letter, to A. V., 11, Salisbury Square, Fleet Street, E.C.

Wanted, Hydrated Sesquioxide of Iron (native)

in powder or soft lumps. Must be nearly free from manganese or other impurities. Samples, with price per ton in casks, to be addressed "Ferrum," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Copper Extracting Works (Wet Process).—

Wanted, to Sell Three Hundred Tons of Cinders; would lend use of Works to extract them. A Complete Phosphorous Works to Let at a Nominal Rent.—Address, in first instance, G. J. Blower, 38, Lowe Street, Whitmore, Wolverhampton.

L. OERTLING, TURNMILL STREET (OPPOSITE FARRINGDON STREET) STATION.

MANUFACTURER OF
CHEMICAL, ASSAY, & BULLION BALANCES.

Maker to the Bank of England, Assay Office
of the Royal Mint, &c., &c.

By Appointment.

COUNCIL MEDAL, 1851. FIRST CLASS MEDAL, 1854 and 1862.

FILTER-PRESSES.

ORIGINAL INVENTORS AND PATENTEES

NEEDHAM AND KITE,
ENGINEERS,

PHŒNIX IRON WORKS, VAUXHALL, LONDON

Established A.D. 1853.

MAKERS OF FILTER-PRESSES OF—
Wood, Iron, Gun-Metal, Copper, Bronze, Lead.
For Freezing, Heating, Washing during Filtration under High Pressure.

Prices according to requirements.

Silicates of Soda and Potash in the state of Soluble glass, or in CONCENTRATED SOLUTION of first quality, suited for the manufacture of Soap and other purposes, supplied on best terms by W. GOSSAGE and Sons, Soap Works Widnes, Lancashire.
London Agents, COSTE and Co., 19 and 20, Water Lane, Tower Street, E.C., who hold stock ready for delivery.

PROF. HUGHES'S MICROPHONE,

Price 10/6, 15/, 21/.

The 20s. 6d. is a neat instrument in polished mahogany case for the table or pocket.

The 15s. is a more sensitive instrument. It will magnify delicate sounds, and render audible sounds, such as the tramp of a fly in walking.

The 21s. instrument includes a 3-cell battery and 10 yards of conducting wire.

M. JACKSON & CO.,
65, BARBICAN, LONDON, E.C.
SCIENTIFIC APPARATUS MANUFACTURERS.

Price Lists 3d. and 1s. each.

PRUSSIAN BLUE

Ten Tons Material containing over 28 per cent ferro-cyanide (on dry basis).

GAS PURIFICATION & CHEMICAL CO., LIMITED,
162, PALMERSTON BUILDINGS,
OLD BROAD STREET. E.C.

MR. EDWARD T. BARRETT,
ACCOUNTANT AND FINANCIAL AGENT,
Gives information without charge to Investors in Stocks and Shares, and conducts the Sale of

ALL CLASSES OF SECURITIES

on reasonable terms.

Mortgages are also effected for inventors and others at fair rates.

Patents secured for Inventions relating to Electricity and Mining Chemistry.

Advice and instruction given in all matters of Account.
38 GREAT ST. HELEN'S, E.C.

Methylated Spirits.—David Smith Kidd,
Licensed Maker, Commercial Street, Shoreditch, N.E.,
Also FINISH, FUSEL OIL, and RECT. NAPHTHA.

THE PORION EVAPORATOR. UPWARDS OF 60 AT WORK.

May be seen Evaporating 16,000 Gallons of Water per Twenty-four Hours, with a duty of 13 lbs. Water per lb. Fuel.

SOLE AGENT FOR UNITED KINGDOM,
R. C. MENZIES,
MUSSELBURGH. N.B.

GEOLOGY.—In the Preface to the Student's ELEMENTS OF GEOLOGY, by Sir Charles Lyell, price 9s., he says:—"As it is impossible to enable the reader to recognise rocks and minerals at sight by aid of verbal descriptions or figures, he will do well to obtain a well-arranged collection of specimens, such as may be procured from Mr. TENNANT (149, Strand), Teacher of Mineralogy at King's College, London." These Collections are supplied on the following terms, in plain Mahogany Cabinets:—

100 Specimens, in Cabinet, with 3 Trays..	£2 2 0
200 Specimens, in Cabinet, with 5 Trays..	5 5 0
300 Specimens, in Cabinet, with 9 Drawers ..	10 10 0
400 Specimens, in Cabinet, with 13 Drawers ..	21 0 0

More extensive collections at 50 to 5000 Guineas each.

SAMUEL HENSON, MINERALOGIST, &c.,

277, STRAND (LATE OF NO. 113 A), LONDON, W.C.
COLLECTIONS OF MINERALS, ROCKS, AND FOSSILS from 6s.

Lessons Given. Analyses Made.

THE CHEMICAL NEWS.

VOL. XXXIX, NO. 1005.

NOTE ON STEEL WELDING.

By SERGIUS KERN, M.E., St. Petersburg.

In some articles inserted in this journal the author stated that pure steel, nearly free from phosphorus and sulphur and containing 25 to 30 per cent of carbon, stands easily the process of welding, if, indeed, the work is done with care and by clever workmen.

It may be mentioned here that to a steel ship-plate, 2 ft. wide and $\frac{1}{2}$ inch thick, a steel plate ($2' \times 2' \times \frac{1}{8}''$) was easily welded, and a perfectly clean and good joint was received.

In another case steel strips ($6'' \times 4'' \times \frac{1}{8}''$) containing 25 to 26 per cent of carbon were welded together; very often after cooling the plate was bent double, through the weld, without the least fracture in or near the welded part. In some experiments such plates were bent at a dark heat, and they often, not always, resisted this severe test, as it is known that at this temperature the steel is more liable to break. These trials show that Russian Bessemer steel is of a very good quality.

TENACITY OF STARCH.

By GEORGE WHEWELL, F.I.C., F.C.S.

In consequence of the large quantity of farina (potato starch) which is used for the sizing and stiffening of yarn and cloth, the question often arises—Given several samples of starch, which will make the stiffest cloth and which has the greatest tenacity? To my mind the best method devised so far is the one used by Shier, and is as follows:—24 grains of the sample of starch are mixed with 400 grains of distilled water, and boiled with constant stirring for three minutes, then poured into conical test-glasses and allowed to stand for two hours; at the end of which time a flat metal disk seven-tenths of an inch in diameter, and not weighing less than 50 grains, is placed on the jelly and weights added until the skin is broken and the disk sinks.

In working the above method I find a difficulty in manipulating the weights on account of the smallness of the disk. If after a 50- or 100-grain weight has been placed on the disk you attempt to place a few smaller ones on also, the pressure is exerted unevenly, and the jelly is cut by the edge of the disk and not broken uniformly. I have devised the following modification, which I have used for the last three years, and find it to answer very well. The principle is to ascertain the number of grains required of any sample of starch which, when made into a jelly, will support a 100-grain weight for five minutes without breaking the skin. I have examined a large number of samples of farina, and find the number of grains required is from 18 to 28.

To determine the tenacity of a sample of farina I take, say, six conical shaped test-glasses 1 ounce capacity, and label the feet 18, 20, 22, 24, 26, and 28. Using a 2-ounce evaporating dish, I weigh out 18 grains of the farina, mix it with 26 c.c. of distilled water, and boil with constant stirring for three minutes. Pour it into the test-glass marked 18, and shake to make the surface of the jelly level, book the time, and allow to cool for exactly two hours. At the end of this time I take a 100-grain weight (mine being thirteen-twentieths of an inch in diameter), and place it on the jelly. If it is supported for more than

five minutes I place it on each of the others in succession until I come to the one through which it sinks, then I have got the tenacity to within 2 grains. The intermediate number will be found to support the weight for exactly the right time. The number of grains required I call the tenacity. If the tenacity of one sample is 18 and the other 28, it means that it requires 28 lbs. of one sample to give the same stiffness as 18 lbs. of the other.

NOTE ON CHLORIDE OF CALCIUM.

By O. GLUGE, Sarrebrück.

THE manufacture of soda by the ammonia process has, during the last few years, been much developed, owing to the advances made by Mr. E. Solvay, and is likely to become more generally employed. It is possible that it may ultimately supersede Leblanc's method, as improvements are being constantly introduced into it.

The reaction which occurs in this manufacture, as all your readers are aware, takes place between bicarbonate of ammonia and chloride of sodium. Bicarbonate of soda is precipitated and hydrochlorate of ammonia remains in solution. The bicarbonate is separated by filtration, and the solution is employed to furnish fresh bicarbonate of ammonia. This is done by distilling the solution with lime; then ammonia is disengaged and a strong ley of chloride of calcium is left in the distilling apparatus.

I am anxious to direct the attention of your readers to this latter product, which is formed in considerable quantity and which is commonly thrown away as useless, as it has hardly been employed hitherto in manufacturing processes.

It would be very desirable that men of science and manufacturers should endeavour to ascertain if a more extended use could be made of a product which can be got at such a cheap rate. The manufactures of soda by the process above mentioned can furnish chloride of calcium in quantity, in solution, in crystals, or even in the fused state to diminish the cost of carriage.

ON THE DETERMINATION OF SPECIFIC GRAVITIES.

By S. F. PECKHAM.

In the *CHEMICAL NEWS* (vol. xxxviii., p. 300) I notice an excellent article "On the Determination of Specific Gravities." The author's points are well taken in reference to the importance of some uniform method either of performing the operation or of confuting results, and his suggestions could with great propriety be referred to some committee of one of the Societies for a report and recommendations that might be generally adopted.

Having occasion some years ago to take the specific gravity of some small quantities of distillates from petroleum products, I was led to adopt the following method, which was found to be entirely successful with so small a quantity as 3 cubic centimetres.

I prepared a cube of aluminium, which was intended to be of 1 c.c., but was accidentally obtained smaller. This was suspended by a platinum wire of the smallest size, and weighing only a few milligrams. The wire was first weighed, and then attached to the cube, which was then weighed in air, and then weighed just immersed in distilled water, and then in the oil. The difference between the weight in the air and in water gave the weight of the water; the difference between the weight in air and in oil gave the weight of the oil. The weight of the oil divided by that of the water gave the specific gravity of the oil.

This method admits of perfect control of the volume of

the liquids compared, and of just as perfect control of the temperatures as any other method. Moreover, it admits of very rapid execution and of operating on very small quantities of liquid. For taking the specific gravity of all ordinary oils and other non-corrosive liquids a cube of aluminium would be superior to a cube of platinum, on account of its lower specific gravity, and its permanence in the air renders it superior to any other of the so-called base metals.

For the class of liquids named I have found the results obtained by this method more satisfactory than those obtained by the bottle when the quantity available was unlimited; I therefore recommend the method without hesitation as applicable to very small quantities of liquid, as reliable, and as incomparably more rapid of execution than any other method with which I am acquainted.

It has often been my custom when ascertaining specific gravities for purposes of comparison to cool the oils to zero Centigrade. This temperature is very easily obtained by immersing the vessel in fragments of ice placed in a funnel from which the melted ice-water can readily flow away. It may not be generally known that water in which pieces of melting ice are floating will rarely cool a vessel to zero, usually not below two degrees. If a tripod holding the funnel is placed over the balance-pan, and a funnel is selected with a long neck bent nearly at a right angle, the water from the melting ice may be discharged into a beaker to one side, while the vessel, holding only a few c.c. of liquid is cooled completely to zero with the least possible trouble.

For purposes of comparison this arrangement furnishes results often of great value in technical operations in which rapidity of execution is often of more importance than that fastidious regard for accuracy which cannot be overestimated in questions relating to the absolute "constants of nature."

Chemical Laboratory, University of Minnesota,

ON THE NEW SUBSTITUTE FOR LITMUS.

By GREVILLE WILLIAMS, F.R.S.

WHILE engaged in preparing a Supplement to my "Hand-book of Chemical Manipulation" I made inquiries in several directions, with the view of ascertaining what improvements had recently been made in the volumetrical determination of acids and alkalies. Amongst the persons consulted was my friend Dr. Otto N. Witt, who kindly pointed out to me that the "orange 3" of Porrier formed an excellent substitute for litmus. This new coal-tar derivative was introduced into commerce about two years ago: I believe, however, that its manufacture has been almost entirely, if not quite, abandoned in favour of "orange 4" or tropæolin OO. This "orange 3" had, before its introduction into commerce, been studied independently by Dr. Witt and M. Griess; and M. Lunge, in the *Berichte der Deutschen Chemischen Gesellschaft*, expressly mentions it as an indicator. Its constitution will be apparent from its chemical name, dimethyl-amido-azobenzol-sulphonate of ammonium.

Lunge has shown that, under certain circumstances tropæolin and "orange 3" are superior to litmus, as they are unaffected by carbonic acid and sulphuretted hydrogen; they are therefore especially valuable in the analysis of soda residues.

As this matter possesses considerable interest and importance to those who have much to do with the determination of acids and alkalies, I have subjected "orange 3" and litmus to a careful comparison. I selected it instead of tropæolin, as it is much more delicate in its reactions.

Different specimens of litmus somewhat vary in their sensitiveness to acids and alkalies; that with which I

worked on this occasion ceased to indicate with sulphuric acid when more dilute than 1 to 50,000. The new indicator, on the other hand, remained sensitive to 1 part of sulphuric acid in 100,000 of water.

The solution of the indicator which I employ is made by dissolving 1 centigramme in 100 c.c. of distilled water, and contains therefore 1 part in 10,000. Even at this great dilution the liquid is of a full orange colour. It is worthy of remark that 1 centigramme of the substance is sufficient for five hundred determinations of acid or alkali; its cost is consequently inappreciable. It has also the advantage over litmus that its solution is less liable to decomposition on keeping.

The quantity of the solution of the indicator, of the strength given above, to be used in each determination is from one to two-tenths of a cubic centimetre. When this small quantity is added to a solution containing an alkali to be tested, there is no perceptible colouration as long as it is alkaline; but the faintest trace of acid turns the solution a pale but distinct pink tint, which is easily seen if the beaker be placed upon a sheet of white paper.

The best way of applying the test is, after each addition of acid from the burette, to allow a drop of the indicator to fall on the surface of the liquid in the beaker after the contents have been well stirred. By this mode of proceeding the indicator is distributed over a smaller space, and the reaction is therefore more distinct.

An immense advantage which this indicator possesses over litmus is that it is entirely unaffected by carbonic acid; the solution need not therefore be boiled, and the operation consequently takes much less time; in fact, four operations can be made in the same time as one with litmus. That without boiling the solution it competes perfectly with litmus as regards accuracy may be judged from the following table:—

Determination of Carbonate of Sodium Volumetrically.

One c.c. of the standard sulphuric acid = 0.051176 grm. of carbonate of sodium.

Carbonate of Sodium taken. Grms.	Standard Sulph. Acid used. Cub. centims.	Percentage of Carb. Sodium obtained.	Indicator used.
0.4655	9.07	99.71	Litmus.
0.9345	18.20	99.68	
1.0646	20.75	99.75	Orange 3.
0.6739	13.15	99.86	

In order to determine whether the new indicator gave as accurate results with ammonia as with carbonate of sodium, the following experiments were made upon a solution diluted to 5 per cent for titration:—

Determination of Ammonia Volumetrically.

One c.c. of the standard hydrochloric acid = 0.00697 grms. of ammonia.

Ammonia taken. Cub. centims.	Standard Hydrochloric Acid used. Cub. centims.	Percentage of Ammonia obtained.	Indicator used.
20	28.50	19.86	Litmus.
16	22.70	19.78	
18	25.50	19.75	
18	25.60	19.83	Orange 3.
14	19.85	19.77	
22	31.30	19.83	

It is obvious, therefore, that the new indicator can be employed in the determination of ammonia instead of litmus, and has many advantages over it.

The Banana.—M. Corenwinder.—The total sugar in this fruit when ripe and sound exceeds 20 per cent, three-fourths of which are crystallisable. When over-ripe the total sugar is reduced to from 16 to 14 per cent, whilst the non-crystallisable sugar rises to 11 or 12, thus being not merely relatively but positively increased.—*Comptus Rendus*.

EXAMINATION OF CAOUTCHOUC GOODS.

By DAVID LINDO.

It was stated some time back (Scientific Notes, *Quarterly Journal of Science*, April, 1877) that the use of oxide of zinc in the manufacture of caoutchouc nipples for milk-bottles has almost been abandoned.

This led to the examination of some caoutchouc nipples lately imported from England, and supplied by first-class houses. The examination was afterwards extended to samples of tubing supplied for chemists' use, and a few other caoutchouc goods.

Some specimens of chemists' tubing were found to consist solely of india-rubber and sulphur. Others contained a large proportion of carbonate of lime and a considerable quantity of oxide of zinc, also a little siliceous matter—apparently French chalk. Oxide of zinc was present in very large quantity in all the other goods, and siliceous matter never altogether absent.

The following were more particularly examined:—

- Lot No. 1.—Oval-shaped nipples, stamped F.
 " No. 2.—Oval-shaped nipples, stamped J.
 " No. 3.—Cylindrical nipples, numbered by maker 2, 3, 4.
 " No. 4.—Ring for teething infant.
 " No. 5.—Caoutchouc doll.
 " No. 6.—Tubing for chemists' use, $\frac{1}{2}$ in. diameter.
 " No. 7.—" " " $\frac{1}{4}$ in. "

The ash was estimated in all these samples, and the oxide of zinc. The quantity of carbonate of lime in Lots 5, 6, and 7 was also ascertained.

The zinc estimates were made from the material direct by cutting up the latter very small, and adding one piece at a time to a mixture of pure carbonate of soda and nitre kept in fusion in a porcelain crucible. The mass was dissolved out with moderately dilute acetic acid, the zinc precipitated with sulphuretted hydrogen, the sulphide zinc converted into chloride; precipitated with carbonate of soda, and weighed as oxide.

When two estimates of the same sample were made, different weights of material were employed.

Lot No. 1.

External surface smooth and not easily abraded. Composition not quite uniform. Ash, mean of three experiments, 46.79 per cent. Oxide of zinc from average sample, 44.14 per cent.

Lot No. 2.

Surface smooth and not easily abraded. Composition uniform. Ash, 47.22 per cent. Oxide of zinc, two estimates:—

1st.	43.52 per cent.
2nd.	43.68 per cent.

These nipples contained a little more clay than Lot No. 1.

Lot No. 3.

These nipples exhibited considerable difference in percentage of mineral matter. Their surfaces were quite smooth, but could be abraded rather easily with the finger-nail.

Makers' Numbers.	Ash, Per cent.	Oxide Zinc, Per cent.
2	62.70	60.71
3	52.58	48.89
4	51.68	49.63

Lot No. 4.

Surface very rough and easily abraded. Ash, 32.07 per cent. Oxide of zinc, two estimates:—

1st.	29.01 per cent.
2nd.	29.18 per cent.

Lot No. 5.

Surface very rough and easily abraded. Composition not quite homogeneous. Ash, estimated from sample cut

from different parts, 65.58 per cent. Carbonate of lime, 11.10 per cent. Oxide of zinc, two estimates from average sample:—

1st.	49.98 per cent.
2nd.	49.90 per cent.

Lot No. 6.

Ash, 49.12 per cent. Oxide of zinc, 15.47 per cent. Carbonate of lime, three estimates:—

1st.	30.21 per cent.
2nd.	30.22 per cent.
3rd.	30.45 per cent.

Lot No. 7.

Ash, 48.90 per cent. Two estimates of carbonate of lime and oxide of zinc:—

	Carbonate of Lime, Per cent.	Oxide of Zinc, Per cent.
1st.	30.50	15.34
2nd.	30.82	15.33

Certain acids, when brought in contact with these compositions, were found to produce some curious phenomena, which will be fully described further on.

The acids employed were—

Sulphuric acid	sp. gr. 1.828
Hydrochloric acid	" 1.154
Nitric acid	" 1.374
Acetic acid, containing 63 to 64 per cent anhydrous acid.	

They were employed of the above strengths, and also much weaker, the dilutions being carried out by volume.

The ounce will be understood to mean a fluid ounce. The phenomena alluded to are—

1. Distension of the material from absorption of fluid.
2. The appearance of small elevations on the surface.
3. Crimping of the edges.

These effects appear to be due to the following causes:—

1. The acid has a strong tendency to enter the pores of the material, in consequence of its affinity for the lime or oxide of zinc.
2. Certain acids (notably acetic acid) not only acts solvent on the mineral matters, but also softens the caoutchouc, rendering it in consequence more easy of distension, and at the same time diminishing its power of contracting after distension. The minute state of division in which the vulcanised rubber is left after disintegration of the mineral matter seems to favour this action.
3. The acid entering the pores of the softened material more readily than the solution of zinc or lime salt formed within the pores escapes from them, distension follows.
4. Small elevations will generally appear on the surface of the material, because the distension at first is merely superficial. These elevations are also sometimes produced by escaping gas-bubbles.

If a sharp edge is presented to the action of the acid, crimping of the edge will result, and remain apparent until the action has proceeded to some depth below the surface of the material, and distension has in consequence become more general.

The general effects produced by the acids are described below, and a few examples given of the absorption occasioned by acetic acid, &c. Strictly comparable experiments could not be made with the samples at my disposal (except perhaps with the chemists' tubing), on account of the irregular form, unequal thickness, and various degrees of elasticity.

The appearance which most samples present under the action of acetic acid is very beautiful, especially if observed with a lens. The phenomenon soon becomes apparent to the naked eye, except with extremely dilute acid; but a lens is required to observe it in the early stage, and to

render visible that fine crimping of the edges which constitutes the only apparent effect produced by very weak acid. With the aid of a good watchmaker's eye-glass I have never failed (in numerous trials) to detect the presence of 1 part of anhydrous acetic acid in 3000 parts of water, by immersing a small piece of nipple (weighing 2 or 3 grains) from Lot No. 1 in 10 c.c. of the diluted acid. Distinct crimping was observed with the lens after twelve to twenty-four hours, when the experiment was performed at the ordinary temperature of the laboratory* (78° to 82° F.). If the fluid and sample were heated on the water-bath, in a closed bottle, the reaction was generally obtained in two or three hours.

It is probable that formic acid will be found to produce the same effect, and that the reaction may be rendered available as a means of detecting minute quantities of either acid in the free state in the absence of the other, provided free mineral acids in large quantity are also absent.

I should here observe that all samples of the material will not be found equally sensitive to the action of the acid, a marked difference being observed in some instances between two samples of apparently the same composition.

Action of Sulphuric Acid.

The strong acid decomposes the material in a few hours. Some specimens were observed to crimp slightly when first immersed, others not at all.

Acid 1 in 2† was found to dissolve out oxide of zinc pretty freely, except from those samples which contained a notable quantity of carbonate of lime. After twelve days' immersion in acid of this strength the elasticity of the material seemed but slightly impaired. Not the slightest crimping was produced, nor was weaker acid found to occasion it. Acid 1 in 20 dissolved out enough zinc from most samples to be readily detected in the fluid after thirty-six hours' immersion.

Action of Hydrochloric Acid.

A piece of No. 1 was immersed in about four times its weight of strong acid. In half an hour a notable quantity of zinc was found in solution. Pieces of No. 1 and No. 5 were immersed in excess of strong acid and examined with lens. Numerous gas-bubbles from No. 5, and a few from No. 1. Cut edges acquired a reddish tinge. After two days both samples had acquired a reddish colour all over. Decided crimping. Sulphur had separated. Some distension of material generally. After four days removed samples from acid, and washed. Elasticity somewhat impaired. On cutting, it was seen action had advanced very far into the material. Original thickness about $\frac{1}{4}$ th inch. A nipple from No. 1 was cut in two lengthwise, and immersed in 2 ozs. acid, 1 in 5.

After nine days faint traces of crimping observed with lens. After fourteen days these had nearly disappeared. Removed sample. Washed, dried with towel, and weighed.

Weight	25.17 grains.
Original weight	24.19 "
	0.98 gr.

Adhering moisture would account for the difference. Quantity of oxide of zinc found in *one* ounce of the fluid, 0.22 gr. Material seemed uninjured.

Acid 1 in 20 failed to produce the least appearance of crimping with the most sensitive samples, the specimens being kept under the action of the acid for a month, and examined carefully with the lens almost daily.

* The temperature at which all the experiments were performed except when otherwise stated.

† One volume of sulphuric acid, sp. gr. as stated, mixed with an equal volume of water. The same for all degrees of dilution, and for all the other acids employed.

Action of Nitric Acid.

The strong acid reduces the material to pulp in a few hours. Acid 1 in 5 also effects decomposition, though much more slowly. A piece of No. 1 weighing 20 grains was immersed in half an ounce of acid of this strength, and finally examined after eighty hours (slight crimping had been observed in the interval). On cutting, decomposition was found to have advanced to a considerable depth, leaving apparently only sulphur on both surfaces, which formed a brittle crust. Acid 1 in 10 appeared to have little action beyond dissolving out the metallic oxides and slightly softening the caoutchouc, producing crimping and general distension of the material. No effect of this kind could be obtained with acid weaker than 1 in 100, and very careful inspection with a strong lens was required to observe the faint traces of crimping produced when the most sensitive samples were immersed in acid of this degree of dilution.

Action of Acetic Acid.

Acid of the strength employed in these experiments (or weaker) was found to have very little action on pure vulcanised rubber. Pieces of tubing (composed of the latter) left floating in the acid for days appeared quite unaltered. On mixing the fluid with water, however, it produced milkiness, showing that a small quantity of caoutchouc had gone into solution. The fact that acetic acid has very little action on pure vulcanised rubber renders its extremely energetic action on the mineralised article truly remarkable, especially when it is remembered that as compared with mineral acids its affinity for bases is feeble.

The strong acid dissolves out the mineral matter very readily, and produces distension so rapidly that no elevations appear on the surface of the material, and very slight crimping of the edges is observed.

Distension, however, although it occurs more rapidly with strong than with weak acid, is often sooner arrested with the former than with the latter, and long before the acid has become exhausted. It appears to cease as soon as the fluid contains a certain proportion of salts in solution. From this it follows that a weak acid, other things being equal, may produce as great or greater distension after a time than a strong one. There are, however, so many circumstances that might influence the result (notably the degree of elasticity possessed by the material) that I should hesitate to accept this as the correct view without further and more exact experiments than I have as yet been able to undertake.

The following experiments serve principally to illustrate the bare fact that very considerable distension does take place with the acid, whether weak or strong:—

A piece of nipple from Lot No. 2, weighing 28.72 grs., was immersed in 5 ounces of acid, 1 in 300. After a month the sample was removed, and placed in 5 ounces of fresh acid of the same degree of dilution. The sample was weighed forty-six days after the commencement of the experiment.

Weight, 112.18 grs. Apparent gain, 83.46 grs.

The material could be torn rather easily. A portion ignited left a considerable residue of oxide of zinc.

Lot No. 2, piece weighing 10.83 grs. Lot No. 6, piece weighing 8.10 grs. Immersed together in 1 ounce of the strong acid. Weights after twenty-one days:—

No. 2, 19.80 grs. Apparent gain, 8.97 grs.
No. 6, 17.30 grs. " " 9.20 grs.

Lot No. 1.—Nipple cut in two lengthwise. Weight, 23.59 grs., immersed in 2 ozs. acid, 1 in 10. Weight after fourteen days:—

93.60 grs. Apparent gain, 70.01 grs.

Quantity of oxide of zinc found in 1 ounce of the fluid, 3.78 grs. Material very tender.

Lot No. 1.—Nipple cut in two lengthwise. Weight, 27·89 grs. Immersed in 2 ozs. acid, 1 in 50. Weight after fourteen days :—

138·70 grs. Apparent gain, 110·81 grs.

Quantity of oxide of zinc found in 1 ounce of the fluid, 1·43 grs. Material very tender.

Lot No. 2.—Nipple cut in two lengthwise. Half immersed in 2 ozs. acid, 1 in 10; the other half in 2 ozs. acid, 1 in 50. Original weight of half in acid 1 in 10, 19·97 grs. Weight after fifteen days :—

73·30 grs. Apparent gain, 53·33 grs.

Original weight of half in acid 1 in 50, 15·19 grs. Weight after fifteen days :—

72·80 grs. Apparent gain, 57·61 grs.

The halves presented originally very nearly, if not quite, the same extent of surface, the difference in weight being due to difference in thickness. After being acted on by the acid, the material in both experiments was found extremely tender.

After this considerable distension fluid escapes so rapidly from the pores of the material, on removal from the acid, that the weight obtained only approximately represents the amount of absorption that has taken place.

The amount of mineral matter dissolved out must also be taken into account. If left to dry these distended samples gradually contract to about their former dimensions, but never recover their elasticity unless the action of the acid has been only slight.

In reference to the phenomena of crimping, &c., by far the finest effects are produced by a dilute acid, say 1 in 300. The result obtained in the following experiment (one out of a very large number tried) will serve to illustrate the action of acid of this strength on a fairly sensitive sample of the material :—

Lot No. 1.—Nipple with top cut off; weight 17·9 grs.

Lot No. 6.—Piece of tubing cut off; weight 9 grs.

Immersed both in $\frac{1}{2}$ oz. acid, 1 in 300. Examined after twelve hours :—

No. 1.—Decidedly but finely crimped on cut edge, quite apparent to naked eye. Surfaces slightly raised. A few bubbles.

No. 6.—Edges slightly crimped. Requires lens to see distinctly. Surfaces very slightly raised.

After thirty-six hours :—

No. 1.—Beautifully and finely crimped. Base ring looks like fine sponge. Exterior surface covered with small round elevations, beautifully regular. Interior surface very slightly raised. No bubbles.

No. 6.—Edges rather strongly crimped. Surface slightly raised. No bubbles.

Very fine effects can be obtained with much weaker acid than 1 in 300, provided the material is sufficiently sensitive. With most of the nipples I have obtained reaction in acid 1 in 2000 (equal to about 1 part anhydrous acid in 3000 parts of water). With sample Lot No. 5 acid 1 in 300 hardly produced any effect.

Old samples that have lost their elasticity to a considerable extent will be found equally inactive.

Falmouth, Jamaica,
January 22, 1879.

THE ELECTRIC LIGHT IN THE BRITISH MUSEUM READING-ROOM.

LAST Monday will henceforth be looked upon as an interesting point of departure in the history of the British Museum Library, for on that day its manifold treasures were for the first time thrown open by night as well as by day to those entitled to use them.

For the past three weeks Mr. Bond, the Principal Librarian, and M. Berly, C.E., the London representative

of the Paris Société d'Electricité, assisted by their respective staffs, have been making repeated experiments on the practicability of lighting up the British Museum Reading-Room by means of the Jablochkoff system of electrical illumination. Having partially determined upon the number and position of the lamps to be used, Mr. Bond decided that on the Monday, Tuesday, and Wednesday of the present week the Reading-room should be kept open until seven o'clock, so that the holders of reading-tickets might have the opportunity of practically testing the value of the welcome innovation. On Monday evening, accordingly, about two hundred readers remained behind after the usual hour for closing, and when, at a few minutes before six o'clock, the twelve Jablochkoff candles in shades of opal glass suddenly burst into light, those present forgot for the moment that they were in a building devoted to silence and study, and evinced their approval of the efforts of the Museum officials on their behalf by breaking into a burst of applause, a sound which we will venture to say has never before been heard beneath Sir Antonio Panizzi's famous dome.

Roughly speaking the Reading-Room is a circle, nineteen-twentieths of which are devoted to the public, the remaining twentieth forming the passage into the Library. In the centre there are three circular desks, the inner one being used for the delivery and return of books, and the two others, which are breast high, for stacking and using the voluminous catalogues. From these run radially nineteen desks divided lengthways by a partition, and lettered from A to T both inclusive, but missing Q, seventeen of which are double, the two end ones being single. At present the first four, A, B, C, and D, are each illuminated by a Jablochkoff lamp, placed on a standard fifteen feet high, fixed exactly in the middle of each desk, being sustained by the longitudinal partition which separates the readers, the remaining fifteen desks being lighted by seven lamps placed alternately. The remaining lamp is placed in the centre of the room, and lights the desks of the Superintendent and his assistants. The general opinion amongst the readers appears to be one of unanimous approbation of this mode of lighting. We have thoroughly tested the matter in a practical manner by reading, writing, tracing, drawing, and painting at one of the first four desks as well as at those which are only lighted alternately. In the first case there is abundant light for comfortable working at any part of the four desks, but in the latter a reader sitting at either end of the illuminated desks has to twist himself round most uncomfortably to get out of his own shadow. We venture to think, therefore, that for the new mode of lighting to be thoroughly satisfactory to all, the whole of the nineteen desks must each be provided with a lamp, thus rendering the imitation of daylight as perfect as need be.

It is agreed on all hands that the light is mellow and soft, and most agreeable to work by. Now and then, it is true, there is a sudden flutter in the light, and occasionally it waxes and wanes slightly, but these defects will no doubt disappear when everything is in full working order.

The source of electricity is a 20-light duplex Gramme machine of the latest construction, worked by a Robey portable engine of 16 horse-power nominal. There are four circuits of five lamps, but only sixteen are used at present; that is to say, twelve in the Reading-Room, one in the Entrance Hall, one under the portico, and two in the machine and engine-shed. The machine and its engine are placed outside in a wooden erection at the north-west corner of the Museum buildings, about 200 yards distant from the Reading-Room.

The four candles used in the lamps at desks M, O, R, and T are of an improved kind lately invented by one of M. Berly's assistants, and are now tried for the first time. They differ from the ordinary Jablochkoff candles in the insulating material between the carbons being replaced by a composition which we suppose must be a feeble conductor. Extinction, except for a moment, is therefore impossible. The use of the carbon bridge for

lighting is consequently entirely obviated. Not only this, but one, two, three, or the whole of the four candles may be lighted or extinguished at will simply by turning the handle of the commutator, or if one goes out it re-lights itself automatically without extinguishing its neighbours.

It would, of course, be premature to speak of the cost of permanently carrying out this immense boon to students and literary men generally; we may, however, mention that a reduction has recently been made in the price of the ordinary ninety-minute candles of something like 40 per cent. That the innovation is already highly appreciated is shown by the large attendance of real workers on the three evenings in question, and by the almost unanimous chorus of approbation indulged in by readers of all classes. The Société d'Électricité deserves great credit for the public spirit they have shown in gratuitously supplying everything necessary for making this interesting experiment.

Mr. Bond and his able coadjutors seem determined to extend the use of the treasures under their charge in every possible direction, and it ought to be the duty as well as the pleasure of the literary, artistic, and scientific press of this country to strengthen their hands by generously commending and seconding their well-intentioned efforts.

PROCEEDINGS OF SOCIETIES.

PHILOSOPHICAL SOCIETY OF GLASGOW.

CHEMICAL SECTION.

Ordinary Meeting, February 10, 1879.

Mr. J. J. COLEMAN in the Chair.

THE first paper was read by Dr. JOHN CLARK, "*On the Action of Phosphuretted Hydrogen on the Animal Organism.*" His experiments were carried out in conjunction with Dr. Henderson. Small animals, usually rats, were introduced into the jar. There appeared to be considerable difficulty in breathing, and itchiness of the skin. Death took place usually within half an hour. A very small amount of gas has a fatal action; even 1 part in 5000 causes death. The blood was dark and venous, and the lungs inflamed. Portions of the liver and blood were tested for phosphorus compounds by introducing them into a flask in which hydrogen was being evolved from zinc and hydrochloric acid. The flame of the hydrogen had a green colour, and exhibited a spectrum of green bands, characteristic of phosphorus.

Mr. TATLOCK read the second paper, "*On Magnetic Iron Sand from the Kyles of Bute.*" This sand forms black streaks on the Argyllshire shore. It is separable into two portions by the magnet, both of which have the same appearance and crystalline form; one is magnetic, and the other not. On analysis the magnetic portion was found to contain 83.55 per cent of Fe_3O_4 and 15.6 per cent of Fe_2O_3 ; and the non-magnetic portion contained 0.67 per cent of Fe_3O_4 , and 97.64 per cent of Fe_2O_3 . If the magnetic variety had been oxidised to the non-magnetic variety no disintegration of the crystal had taken place.

The last paper was read by Mr. J. B. HANNAY. The subject was, "*Variation in the Magnetic Constituents of Minerals.*" It has been observed that many rocks are feebly magnetic. The author's method of determining the amount of this magnetic attraction has been elsewhere described. It consists of suspending a sample of the rock to the beam of a balance, and determining the amount of oscillation produced by a magnet placed above the pan. The magnetic constituents of these rocks, comprising specimens of pyrochlor-obsidian, natrolite, rhodonite, and gneiss, were separated by pulverisation and

attraction by a magnet. The portion separated was again reduced to powder, and the magnetic portion again separated, and so on till no non-magnetic residue remained. The magnetic portions all had almost the same specific gravity, and after deduction of a silicate of ferroso-ferric oxide, $\text{Fe}_3\text{O}_4 \cdot 2\text{SiO}_2$, the residue was found to approach the composition of a spinel, composed of an oxide of the formula $\text{M}_2\text{O}_3 \cdot \text{MO}$. This residue was magnetic, when iron constituted either one or other of the oxides, the remaining oxide consisting of alumina or lime. Mr. Hannay's conclusion, therefore, is that such a mixed oxide, or spinel, may possess magnetic properties when associated with magnetic silicate of ferroso-ferric oxide.

EDINBURGH UNIVERSITY CHEMICAL SOCIETY

February 12, 1879.

Mr. GEORGE MACGOWAN, F.R.S.E., in the Chair.

A PAPER was read by Dr. W. INGLIS CLARK "*On the Action of Chlorinated Substances on Alcohol,*" in which he described the practical method of preparing chloroform, and the chemical reactions which most probably occur in its formation.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—When the Institute of Chemistry was first proposed the promoters gave great offence by holding hole-and-corner meetings of their personal friends, instead of inserting an advertisement in your columns asking all professional chemists to meet together and discuss their mutual wants with a view of forming an association.

Whatever excuse there might have been at that time for such a course of procedure, it is surely unnecessary and undesirable to continue the same system.

Throughout the year 1878 the Members of the Institute heard of absolutely nothing being done by the Council to advance the interests of the profession, until in December—just before the new subscriptions fell due—the Institute showed a faint sign of life, and a meeting was held, at which the important subject of "Trade Certificates" was discussed.

This seemed a step in the right direction, and we looked forward anxiously for a verbatim report of the proceedings. With a large number of Members scattered all over the kingdom, and with ample funds for the purpose, our Council surely could not have contemplated anything less.

Judge then of the disgust of myself and other subscribers when it leaked out that the executive dared not publish a report of the meeting because nearly all the speakers upheld the system of giving certificates for advertising purposes. They were expected to curse, but verily they blessed them altogether. But why should the discussion not be published? Have the executive discovered that they have been cherishing a snake? Are some of the worst sinners to be numbered amongst the very elect, i.e., the Council of the Institute of Chemistry of Great Britain and Ireland?

Now, Sir, I protest against this hole-and-corner business. Every Fellow of the Institute has a *right* to know all that occurs at the public meetings of his society, and the attempt to prevent publicity of discreditable proceedings will, if persisted in, speedily prove the ruin of the Institute.

In a few days' time a second conference will be held, at which the subject of the "Adulteration of Food and

Drugs" will be discussed. While deprecating the choice of Dr. Voelcker as the leader of the discussion—for, eminent as he is in his own department, his opinions command no respect among those chemists who have had special experience in the examination of food and drugs—it is to be hoped that his speech and that of all others who take part in the debate will be fully reported and circulated among the Members.

As the Council of the Institute allowed the year 1878 to pass without moving a finger to advance the interests of the profession, and as there are ample funds in hand, I had hoped they would have had the discretion not to make any call for 1879. As it is, I shall wait to see what the "Government Programme" is before I pay my subscription, and I hope the other Members will do the same. In short, I challenge the Council to show what they intend to do with the money now in hand.—I am, &c.,

A DISGUSTED PROMOTER.

THE BESSEMER PROCESS FOR TREATING SULPHIDES.

To the Editor of the Chemical News.

SIR,—With reference to the remarks on my experiments in the CHEMICAL NEWS, vol. xxxix., p. 94, that "The analyses made seem to show that in the regulus obtained there is often much less sulphur than corresponds to the formula FeS —a fact that points to a lower sulphide of iron than any hitherto recognised," Is it not possible the excess of iron present may be accounted for in another way, viz., by the presence of metallic iron?

I propose making the following experiment in a Bessemer provided with a lime lining, viz.—To Bessemerise FeS with a hot blast and without adding silica, and I expect (provided the temperature is sufficiently high) that the protoxide of iron formed will react on the protosulphide of iron and produce metallic iron with the evolution of sulphurous acid.—I am, &c.,

JOHN HOLLWAY.

7, Jeffrey's Square, St. Mary Axe, London, E.C.,
March 1, 1878.

ALUM IN FLOUR AND BREAD.

To the Editor of the Chemical News.

SIR,—Mr. Penney, in his article on "Alum in Flour and Bread" (CHEMICAL NEWS, vol. xxxix., p. 80) remarks that the logwood test for alum is to be thoroughly relied on as a qualitative test if properly applied, and that it is of little consequence whether the solution is old or new. In this conclusion I quite agree with him, and I wish to point out a reason for its sometimes failing.

I have noticed that if the mixture of logwood and carbonate of ammonia solutions is allowed to stand a short time before applying it to the flour or bread containing alum, it imparts a dirty brown colour, and sometimes makes no change in the colour, according to the length of time it has stood, but if applied immediately it never fails to give the blue colour.—I am, &c.,

ALFRED J. M. EDGER.

Laboratory, 13, Dean Street, Newcastle-on-Tyne,
February 27, 1879.

THE DISCUSSION ON WATER ANALYSIS AT THE CHEMICAL SOCIETY.

To the Editor of the Chemical News.

SIR,—Will you allow me to repeat what I said at a recent meeting of the Chemical Society, since, from my words not being fully reported, an inaccurate statement was attributed to me, and, furthermore, because I should like

to add one or two remarks which I omitted on the occasion referred to.

I drew attention to the fact that Prof. Dittmar had very carefully described the details of a method of burning water residues in the CHEMICAL NEWS about a year ago. I stated that, having tried this method upon some ten or twelve waters, I had found it yield very accurate results. These waters contained exceedingly small quantities of any solid constituents, and especially little organic matters. I described then the process as I had used it, saying that the nitrogen was burned with soda-lime in a current of hydrogen. Will you allow me to add that the ammonia, instead of being collected in acid, was absorbed by pure distilled water, and with perfect condensation. Prof. Dittmar mentions the constant presence of ammonia in mineral acids, and I experienced a serious difficulty in attempts to prepare acids which, after neutralisation with pure sodic carbonate, would not give a strong colouration with the Nessler test.

The soda-lime used, both to absorb the carbon dioxide and to burn the organic matter for nitrogen, was prepared from pure soda and ignited marble. It was finely pounded, and passed through one sieve on to a finer one, so as to free the material from dust, and at the same time remove all pieces larger than a pin's head.

I believe this combustion process will satisfy the requirements of all those who have only an occasional need of such a method of analysis.—I am, &c.,

W. N. HARTLEY.

King's College, March 4, 1879.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 5, February 3, 1879.

Remarks on the Third Reply of M. Pasteur.—M. Berthelot.—A continuation of a stale and unprofitable discussion.

Fermentation of Cellulose.—P. Van Tieghem.—It does not seem that there is a diastase of cellulose formed in excess by amylo-bacteria and acting at a distance from it. Microscopic observations show that the solvent action of the amylo-bacteria upon cellulose is produced by direct contact. If the hypothesis of a diastase naturally offers itself to the mind to explain the first stage of the fermentation of cellulose and in general of the insoluble matters produced by living beings it must be recognised as not readily verifiable.

Liquefaction of Silicide of Hydrogen.—M. Ogier.—The author has performed this experiment with the apparatus of Cailletet. At ordinary temperatures (about 10^5) liquefaction does not take place under pressures of 200 to 300 atmospheres. On the contrary, from 50 atmospheres the cooling due to the release determines the production of a thick mist and of a manifest trickling of liquid down the sides of the tube. Under these conditions the gas is at a temperature bordering upon its critical point. It suffices, indeed, to cool it a few degrees below zero in order to effect a total condensation. Hydric silicide is liquid at -11° at the pressure of 50 atmospheres; at -5° under 70 atmospheres; at -1° under 100 atmospheres, whilst at 0° it remained liquid up to 200 atmospheres. The conditions of the liquefaction of this gas resemble those of marsh-gas, with which it has so many analogies.

Determination of Methyl Alcohol in Commercial Methylens.—C. Bardy and L. Bordet.—The authors point out the imperfections of the ordinary process founded on the transformation of methyl alcohol into methyl

iodide. They effect the conversion in a special apparatus, a figure of which is inserted in their memoir.

The Wagnerite of Bamle in Norway, and on a Retinite from Russia.—F. Pisani.—Wagnerite, a fluoriferous phosphate of magnesia originally met with at Werfen, in Salzburg, is identical with a mineral subsequently discovered at Bamle, in Norway, and provisionally named Kjerulfine. The latter, however, contains a percentage of lime. The Russian retinite was formerly mistaken for a manganiferous garnet.

No. 6, February 10, 1879.

On Fermentations, a Final Reply to M. Pasteur.—M. Trécul.

Fourth Reply to M. Berthelot.—M. Pasteur.

Hydro-electricity and Hydro-magnetism: Experimental Results.—C. A. Bjerknes.—The author has examined the action between two pulsating bodies; between a pulsating body and another which oscillates; and between two oscillating spheres. In all these cases concordant pulsations produce attractions, and opposed pulsations give rise to repulsion.

The Green Phosphorescent Light of the Molecular Shock.—W. Crookes, presented by Th. du Moncel.—An abstract of a paper recently read before the Royal Society.

Dissociation of Chloral Hydrate.—MM. Engel and Moitessier.—The authors, along with M. Wurtz, and in opposition to M. Troost, maintain that chloral hydrate does not exist as a definite gaseous compound, and that its equivalent does not correspond to 8 vols. The dissociation is effected in an atmosphere of chloroform at 61°.

Researches on Beer-yeast.—MM. Schützenberger and Destrem.—Yeast digested alone at 30° for twenty-four hours lost 1·77 per cent of solid matters. If digested along with sugar there is an increase of solids amounting to 11·3 per cent on the weight of the yeast.

Homologues of Oxyheptic Acid.—E. Demargay.—The author has prepared the following homologues:—oxytetric, oxyptenic, oxyhexic, and iso-oxyhexic acids.

Analysis of an Ethiopian Honey.—A. Villiers.—This honey, known by the natives as *tasma*, is found in subterranean cavities in Ethiopia, and is said to be collected by a species of mosquito. Its composition is:—

Water	25·5
Levulose and glucose free from)	
saccharose	32·0
Mannite	3·0
Dextrine	27·9
Ash	2·5
Sundries and loss	9·1

100·0

Process for Enriching Phosphates with a Carbonated Gangue.—L. L'Hôte.—The author heats to bright redness so as to expel the carbonic acid, and then removes the caustic lime formed by lixiviation with very dilute hydrochloric acid. [To the best of our belief a substantially identical process has been for many years in occasional use at the Great Eastern Chemical Works, Stowmarket.]

Bulletin de la Société Chimique de Paris,

No. 1, January 5, 1879.

Examination of some Mineral Waters of Auvergne.—E. Willm.—Not susceptible of useful abstraction.

Transformation of Starch into Glucose by Cold Water.—J. Riban.—The author had prepared, according to Mohr's directions, a solution of salted starch by boiling 1 part of powdered starch in 100 parts of water, saturating with common salt and filtering. After a year the solution became less and less sensitive to iodine, and after three or four years ceased to react with it at all. The liquid

remained limpid and neutral, and on microscopic examination showed no trace of any organised ferments, but it readily reduced cupropotassic reagent and turned yellow on boiling with acids. A special experiment with potassic ferricyanide showed that this reduction was due only in a small part to dextrin.

Determination of the Specific Gravity and Coefficients of Expansion of Liquid Methyl Chloride.—MM. Camille Vincent and Delachanal.—Noticed in the *Comptes Rendus*.

Remarks on the Memoir of E. and O. Fischer on the Constitution of the Rosanilins.—A. Rosenstiehl.—The author considers it as established that there exist no rosanilins containing in their molecule more than 20 atoms of carbon, and that there are three distinct rosanilins, viz., rosanilin- α , decomposable into aniline and paratoluydin, which MM. Fischer designate as pararosanolin, and prove that a single molecule of toluydin enters into its composition; rosanilin- β , decomposable into aniline and orthotoluydin; the authors might call it orthorosanolin; they have not studied, it but confound it with the following. Rosanilin- $\alpha\beta$ (Hofmann's rosanilin), resolvable into aniline, orthotoluydin, and paratoluydin. M. Rosenstiehl at the outset of his researches considered this last compound as a mixture of the two former, but subsequently was led to regard it as a well-defined chemical individual. The beautiful researches of E. and O. Fischer have removed all doubt on this point, and shown that it is the superior homologue of pararosanolin, and not its isomer. The second must be the isomer either of the first or the third.

No. 2, January 20, 1879.

Preparation and Properties of Potassic Cobaltocyanide and of Certain Derivatives.—A. Descamps.—Already noticed.

Memoir on the Curves of Solubility of Salicylic and Benzoic Acids.—E. Bourgoïn.—The curve of solubility of benzoic acid in water is analogous to that of salicylic acid. As far as about 35° the two curves are represented by parabolas closely approximating, but above this temperature they change their nature, becoming modified in the same manner. Benzoic acid, which was at first rather more soluble than salicylic acid, becomes less soluble, so that the two curves intersect each other at 40°, at which point the solubilities are of course exactly the same.

On Laurent's Carminaphtha.—A. Guyard.—The author finds that this compound, whose existence has been doubted, may be prepared by dissolving at a gentle heat 1 equivalent or 128 grms. of naphthalin in a sufficient quantity of glacial acetic acid. On the other hand, 12 equivs. or 600 grms. of chromic acid are also dissolved in a sufficient quantity of cold glacial acetic acid. He then adds at a gentle heat the chromic solution to the naphthalin until the mixture takes a green tint, then, when all the chromic acid has been introduced, he boils for a few minutes. If the whole is then saturated with alkali, or an alkaline carbonate, and the liquid acidulated afresh, the carminaphtha is precipitated in red or brown-red flocks. He concludes that carminaphtha is really a product of the oxidation of naphthalin by chromic acid. When it is formed little carbonic acid is evolved, whilst when phthalic acid is produced carbonic acid is evolved in quantity. Carminaphtha is a very stable compound and dyes wool and silk a deep reddish brown without mordant, the shades thus obtained being less remarkable for beauty than for permanence.

Russian Chemical Society: Session of Nov. 2/24, 1878.—M. Wagner presented researches by MM. Schirokoff and Saytzeff on allyl-diethyl-carbinol, and a communication by M. Sorokine on the oxidation of diallyl and on the hexylic glycol thus derived. M. Barsilovsky sent a memoir on the azo-derivatives of toluen. A paper of M. Ponomareff's was read, on compounds belonging to the

uric acid group. M. Menschoutkine laid before the Society the results of researches on the formation of compound ethers corresponding to the non-saturated tertiary alcohols. M. Gustavson communicated a paper on the addition-products formed by chloride of aluminium with benzine and toluene. M. Saytzeff gave a preliminary account of a hydrocarbon obtained by acting with dilute sulphuric acid upon allyl-dimethyl-carbinol.

Justus Liebig's Annalen der Chemie,
Band 194, Heft 2 and 3.

On Daubréelite, a New Meteoric Mineral.—J. Lawrence Smith.—This mineral, in a state of purity, consists of shining black fragments of more or less foliaceous structure, somewhat resembling molybdenite. It is not in the slightest degree attacked by hydrochloric acid, cold or hot, but dissolves slowly in warm nitric acid, without depositing sulphur. Its specific gravity = 5.01. Its composition is:—

Sulphur	42.69
Chromium	35.91
Iron	20.10

98.70

Researches on Ketons of the Aromatic Series.—W. Stadel.—This paper also is not adapted for abstraction.

Band 195, Heft 1 and 2.

Nitrosalicylic Acids and the Isomerisms of the Benzol Derivatives.—H. Hubner.—A very extensive memoir, utterly incapable of useful abstraction.

Researches on the Non-saturated Acids (Second Treatise).—Rudolph Fittig.—This memoir, which extends to upwards of 100 pages, comprises:—Further contributions to the knowledge of fumaric and maleic acids, by C. Petri; investigations on the oil of Roman camomile, which, again, consists of a paper, by H. Kopp, on the organic acids obtained on the saponification of the above-mentioned oil; one by Julius Köbig on the several ingredients of Roman camomile oil; one by A. Pagenstecher on angelic and tiglic acids; and a note by R. Fittig himself on the constitution of these two acids. The third grand division of the memoir is devoted to the non-saturated aromatic acids. Under this head R. Fittig and F. Binder describe the addition products of cinnamic acid; E. Posen treats of amido-hydro-cinnamic acid, otherwise known as phenyl-amido-propionic acid; R. Fittig and C. Wurster describe atropaic and isatropaic acid; and R. Fittig adds certain theoretical considerations on the formation of non-saturated hydrocarbons from the addition-products of the non-saturated acids.

Halogen Substitution-Products of Æthan.—W. Stadel.—The author describes the action of chlorine upon ethyl chloride, ethylen chloride, ethylen chloride, dichlorethyl chloride, and mono-chlorethylene chloride, adding the remark that he has studied penta-chlorethan, and is at present engaged with hexa-chlorethan, his results on both which bodies will shortly appear.

Chloro-brom- and Brom-Substitution-products of Ethylen.—Dr. J. Denzel.—The author describes the preparation and properties of α -chlor-brom-ethylen, α -chlor-dibrom-ethylen, α -dichlor-brom-ethylen, dichlor-dibrom-ethylen, and the brom-substitution-products of ethylen.

Nomenclature and Boiling-points of the Chloro-brom-substitution-products of Æthan and Ethylen.—Dr. J. Denzel.—The most important part of this paper is a table of boiling-points.

Simple Apparatus for Regulating and Varying the Atmospheric Pressure in Distillations, Determinations of Boiling-Points, &c.—W. Stadel and E. Hahn.

Reduction of Analytical Weighings to a Vacuum.—G. F. Becker.—These two papers require the accompanying plates. Becker lays down the law that the correction for the influence of the atmosphere decreases in proportion to the increase of the square of the specific gravity.

Experimental Researches on Hydrogen Peroxide.—E. Schöne.—The author examines the behaviour of hydrogen peroxide with potassium iodide, a point of great importance for ozonoscopic observations. The author concludes from numerous careful experiments that perfectly pure hydrogen peroxide, whether in the state of vapour or in aqueous solution, and whether in a concentrated or diluted condition, liberates iodine from potassic iodide.

Hexylens Formed from Tertiary Hexylic Alcohols and on their Polymerisation.—L. Jawein.—Not susceptible of useful abstraction.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale.

No. 61, January, 1879.

Experiments Recently Undertaken to Dephosphorise Cast-iron.—M. Gruner.—The author has ascertained that dephosphorisation may be effected in the Bessemer apparatus or the Siemens furnace if the siliceous lining in both is dispensed with and refractory basic materials are used instead.

Metallurgy of Nickel.—As a note to Mr. A. H. Allen's paper translated from the *Journal of the Society of Arts* is appended an illustrated memoir by Badoureaux on the treatment of European ores of nickel and cobalt.

Les Mondes, Revue Hebdomadaire des Sciences.

No. 6, 1879.

The Berlin Aniline Colour Company have issued a lengthy reply to the note by MM. Bindschedler and Bush on malachite green, inserted in the *CHEMICAL NEWS*, vol. xxxix., p. 61. They deny that a green dye can be industrially prepared from nitrobenzol and dimethyl-anilin by an oxidation process.

No. 7, February 13, 1879.

This issue contains a long account of the chemical manure works of M. Coquerel and Co., near Paris. This establishment, though only opened in 1874, sold, in 1877, six million kilos. of different manures.

MISCELLANEOUS.

The Royal Agricultural College, Cirencester.—The rumoured resignation of Prof. Church is incorrect. The Committee of Management of the Agricultural College are about to determine whether, after his marriage, he can retain his post without residing in the College precincts. Should this chair become vacant intending candidates may find the following extracts from the Collège Bye-Laws of some use:—

"XXI. The Principal . . . shall exercise supreme control over all Departments, Moral, Instructional, and Domestic, and over the Library, Museum, Gardens, Laboratory, and Veterinary Hospital.

"XXII. He . . . shall regulate the frequency and duration of the several Lectures and periodical Examinations, and all other matters of detail.

"XXIV. The Professors shall be appointed by the Principal, and be removable by him.

"XXVI. No private tuition by Professors is allowed, without the previous consent in writing of the Principal, to be separately given in every case.

"XXVII. The Professors shall be required to take a share in the maintenance of good order and discipline amongst the Students, subject to such regulations as the Principal shall appoint.

"XXVIII. All communications from the Professors and other officers of the College to the Council or Committee of Management shall be made only through the Principal."

The last Professor appointed has had to promise that he will engage in no literary work without leave from the Principal.

NOTES AND QUERIES.

Chromic Oxide.—Will any of your readers inform me how or where chromic oxide, as recommended by M. Audouin (*Les Mondes*, January 23, 1879) for fire-bricks, crucibles, &c., can be obtained at a cost that would allow of its being used for such a purpose.—CRUCIBLES.

MEETINGS FOR THE WEEK.

MONDAY, 10th.—Medical, 8.30.

Society of Arts, 8. "Dwelling Houses Their Sanitary Construction and Arrangements," by Dr. W. H. Corfield, M.A. (Cantor Lectures.)
London Institution, 5.
Royal Geographical, 1, 8.30.

TUESDAY, 11th.—Civil Engineers, 8.

Royal Institution, 3. "Animal Development," Prof. Schäfer.
Anthropological, 8.
Photographic, 8.

WEDNESDAY, 12th.—Society of Arts, 8. "The Compensation of

Watches, Clocks, and Chronometers," by E. Rigg, M.A.
Microscopical, 8.
Geological, 8.

THURSDAY, 13th.—Royal, 8.30.

Royal Institution, 3. "Sound," Prof. Tyndall.
Royal Society Club, 6.30.
Society of Arts, 8. "The Injurious Effects of the Air of Large Towns on Animal and Vegetable Life, and on Methods Proposed for Securing Salubrious Air," by W. E. Thomson, F.R.S.E.

FRIDAY, 14th.—Royal Institution, 9. "History of Games," by E. B. Tylor.

Quekett, 8.

SATURDAY, 15th.—Royal Institution, 3. "Colbert and Richelieu," by Mr. Walter H. Pollock.

WATTS'S DICTIONARY OF CHEMISTRY.

Seven Volumes, 8vo., price £10 16s. 6d.

A DICTIONARY of CHEMISTRY, and the Allied Branches of other Sciences; founded on that of the late Dr. Ure. By HENRY WATTS, B.A., F.R.S.; assisted by eminent Scientific and Practical Chemists.

"The English language is not rich in lexicons of science. We would point to this work as a model upon which others might be framed. To the practical analyst this work must prove of the utmost value—to the philosophical investigator it must, as the record of all former labours, be a great gain—and to the student who is true to his studies, it will prove an ever-ready guide. Our manufacturers know the value of chemistry, and are many of them experts in the special branches of the science which bear on their particular industries. They require to know the latest discoveries, and to keep them as it were in stock until the march of improvement renders it necessary to apply them. This 'Dictionary' places them in possession of these desiderata."—*Athenæum*.

THIRD SUPPLEMENTARY VOLUME

(Vol. VIII.), completing the Record of Chemical Discovery to the year 1877. In Two Parts, of which the First is now ready, pp. 844, price 36s. cloth.—Part II. in the Autumn.

"We cannot give this volume greater praise than by saying that it is worthy of the European reputation which Mr. Watts's 'Dictionary' has already acquired as a standard work of reference."—*Bristol Mercury*.

London: LONGMANS and CO.

CULLEY'S PRACTICAL TELEGRAPHY.

In One Volume, 8vo., with 132 Woodcuts and 28 Lithographic Plates of Machinery and Apparatus, Price 16s.

A HANDBOOK OF PRACTICAL TELE-

GRAPHY. By R. S. CULLEY, Member Inst. C.E. (Adopted by the Post Office and by the Department of Telegraphs for India.) The Seventh Edition, thoroughly revised and enlarged.

London: LONGMANS and CO.

A Technical Laboratory in London (speciality Coal-tar Products, Aniline Dyes, Anthracen, Artificial Alizarin) is open to receive two or three more Pupils for training in the technical and industrial pursuits.—Apply to M. 305, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

A Chemist of Nine Years' standing, with extensive experience in all branches of the Science, and who has devoted special attention to oils and fats, will be open to an Engagement in April. Highest references.—Address, A., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

A Gentleman of business habits, with a good knowledge of practical chemistry, and well acquainted with several foreign countries, is desirous of an Engagement as Manager, with the view of becoming an active partner, in some well-established sound chemical works manufacturing acids, artificial manure, or aniline colours, and situated in or close to London. Highest references. Communications of principals or their solicitors only to be addressed to G. H., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Advertiser, who has had many years' practical experience in experimental and analytical chemistry, is desirous of an Appointment, either in England or Colonies, as Chemist or Assistant.—Address, A. E. C., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Young Man, at present engaged in a Tar Work in Scotland, thoroughly experienced in manufacturing liquid ammonia, also sulphate of ammonia from gas liquor, and in refining of benzols and naphthas; with a knowledge of chemistry, German, and French, wishes to improve his position.—Address, S.H., Craigmale Chemical Works, Paisley.

Wanted, Hydrated Sesquioxide of Iron (native) in powder or soft lumps. Must be nearly free from manganese or other impurities. Samples, with price per ton in casks, to be addressed "Ferrum," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, Two Chemists, from this month to the end of August, to take observations of the quantities of acid vapours present in the atmosphere surrounding a Chemical Works during the night and the day. Good references required.—Address, "Atmosphere," care of Lee and Nightingale, Advertising Agents, Liverpool.

TO SULPHURIC ACID AND CHEMICAL MANURE MANUFACTURERS.

A Sailing Tank Barge to be Sold. Capable of carrying 50 tons of acid; fitted with steam pumps; in good condition.—May be seen at Messrs. B. Jacob and Sons' Wharf, Coppera Lane, Church Street, Deptford, from whom all particulars can be obtained.

TO BE LET.—An Eligible Dwelling-House, with Laboratory fitted complete; suitable either for a chemist in analytical practice or for classes in practical chemistry. Possibly a small income.—For full particulars apply to E. and S. Smith, Auctioneers and Agents, 22, Southampton Buildings, Chancery Lane, W.C.

TO PAPER MAKERS, CHEMICAL MANUFACTURERS AND OTHERS.

TO LET, at Low Rentals, Works and Land in Plots of Two to Ten Acres, near Swansea. Coals obtainable from 4s. 6d. per ton. Water good and abundant. Any description of manufactory can be carried on. Excellent Railway, Canal, and Dock accommodation close at hand.—Apply to Richard Hall, Esq., 37, Great George Street, Westminster, or Mr. Thomas Williams, Aberdulaire, Neath, Glamorganshire.

ORGANIC MATERIA MEDICA. BY DR. MUTER.

Analytical Chemists will find this a concise and yet complete book of reference for the isolation and examination of the active principles of drugs. Special appendix on the microscopic characters of the starches in food and drugs. Copious index and qualitative courses or resins, &c.

Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, S.E., and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox.

ROYAL POLYTECHNIC.—BUNYAN'S

PILGRIM'S PROGRESS, illustrated by Dissolving Views and Scenic Tableaux. The allegory has been adapted by Dr. AVELING, and is read by Mr. OSCAR HARTWELL.—THE ELECTRIC LIGHT, by Mr. J. L. KING.—VOYAGES IN THE AIR (a pictorial and experimental lecture), by Mr. T. C. HEPWORTH.—THE STEAM ENGINE, its origin, history, and present perfection; and GAS, what it does and what it can do; both experimental and highly interesting lectures, by Mr. J. L. KING.—In preparation, a dioramic lecture of the ZULUS and their Country, by Mr. W. R. MAY.—Admission 1s.; after 8.45 p.m. (including reserved Stalls), 1s.; Schools and Children under 10, 6d. Open from 12 till 5, and from 7 till 10.

THE CHEMICAL NEWS.

VOL. XXIX. No. 1007

A NEW CHEMICAL INDUSTRY,
ESTABLISHED BY M. CAMILLE VINCENT.*

By Prof. ROSCOE, LL.D., F.R.S.

"AFTER I had made the discovery of the *marine acid air*, which the vapour of spirit of salt may properly enough be called, it occurred to me that, by a process similar to that by which this *acid air* is expelled from the spirit of salt, an *alkaline air* might be expelled from substances containing the volatile alkali. Accordingly I procured some volatile spirit of sal-ammoniac, and having put it into a thin phial and heated it with a flame of a candle, I presently found that a great quantity of vapour was discharged from it, and being received into a basin of quicksilver it continued in the form of a transparent and permanent air, not at all condensed by cold." These words, written by Joseph Priestley rather more than one hundred years ago, describe the experiment by which ammonia was first obtained in the gaseous state.

Unacquainted with the composition of this alkaline air, Priestley showed that it increased in volume when electric sparks are passed through it, or when the alkaline air (ammonia) is heated the residue consists of inflammable air (hydrogen).

Berthollet, in 1785, proved that this increase in bulk is due to the decomposition of ammonia into nitrogen and hydrogen, whilst Henry and Davy ascertained that two volumes of ammonia are resolved into one volume of nitrogen and three volumes of hydrogen.

The early history of sal-ammoniac and of ammonia is very obscure. The salt appears to have been brought into Europe from Asia in the seventh century, probably from volcanic sources. An artificial mode of producing the ammoniacal salts from decomposing animal matter was soon discovered, and the early alchemists were well acquainted with the carbonate under the name of *Spiritus salis urinae*. In later times sal-ammoniac was obtained from Egypt, where it was prepared by collecting the sublimate obtained by burning camels' dung.

Although we are constantly surrounded by an atmosphere of nitrogen, chemists have not yet succeeded in inducing this inert substance to combine readily, so that we are still dependent for our supply of combined nitrogen, whether as nitric acid or ammonia, upon the decomposition of the nitrogenous constituents of the bodies of plants and animals. This may be effected either by natural decay, giving rise to the ammonia which is always contained in the atmosphere, or by the dry distillation of the same bodies, that is, by heating them strongly out of contact with air; and it is from this source that the world derives the whole of its commercial ammonia and sal-ammoniac.

Coal, the remains of an ancient vegetable world, contains about 2 per cent. of nitrogen, the greater part of which is obtained in the form of ammonia when the coal undergoes the process of dry distillation. In round numbers two million tons of coal are annually distilled for the manufacture of coal gas in this country, and the ammoniacal water of the gasworks contains the salt of ammonium in solution.

According to the most reliable data 100 tons of coal were distilled so as to yield 10,000 cubic feet of gas of specific gravity 0.6, giving the following products, in tons:—

Gas.	Tar.	Ammonia Water.	Coke.
22.25	8.5	9.5	59.75 average.

* A Discourse given at the Royal Institution of Great Britain, Friday, February 21, 1879.

This ammonia water contains about 1.5 per cent. of ammonia; hence the total quantity of the volatile alkali obtainable from the gasworks in England amounts to some 9000 tons per annum.

A singular difference is observed between the dry distillation of altered woody fibre as we have it in coal, and woody fibre itself. In the products of the first operation we chiefly find in the tar the aromatic hydrocarbons, such as benzene, whilst in the second we find acetic acid and methyl alcohol are predominant.

The year 1848 is a memorable one in the annals of revolutionary chemistry, for in that year Wurtz proved that ammonia is in reality only one member of a very large family. By acting with caustic potash on the nitrates of the alcohol radicals he obtained the first series of the large class of compound ammonias the primar monamines, Of these methylamine is the first on our list:—

The years that followed, 1849 to 1851, were prolific in ammoniacal discoveries. Hofmann pointed out that not only one atom of hydrogen in ammonia can be replaced by its equivalent of organic radical, but that two or all the three atoms of the hydrogen in ammonia can be likewise replaced, giving rise to the secondary and tertiary amines, by the following simple reactions:—

To these bodies the names of methylamin, di-methylamin, and tri-methylamin were given. They resemble ammonia in being volatile alkaline liquids or gases, which combine with acids to form crystalline and well-defined salts.

Hitherto these compound ammonias have been chemical curiosities; they have, however, recently become, as has so often been the case in other instances, of great commercial importance, and are now manufactured on a large scale.

We are all well aware that the French beet-root sugar industry is one of great magnitude, and that it has been largely extended in late years. In this industry, as in the manufacture of cane sugar, large quantities of molasses or treacle remain behind after the whole of the crystallisable sugar has been withdrawn. These molasses are invariably employed to yield alcohol by fermentation. The juice of the beet, as well as that of cane-sugar, contains, in addition to the sugar, a large quantity of extractive and nitrogenous matters, together with considerable quantities of alkaline salts. In some sugar-producing districts the waste-liquors or spent-wash from the stills—called *vinasses* in French—are wastefully and ignorantly thrown away, instead of being returned to the land as a fertiliser, and thus the soil becomes impoverished. In France it has long been the custom of the distiller to evaporate these liquors (*vinasses*) to dryness, and to calcine the mass in a reverberatory furnace, thus destroying the whole of the organic matter, but recovering the alkaline salts of the beet-root. In this way 2000 tons of carbonate of potash are annually produced in the French distilleries. For more than thirty years the idea has been entertained of collecting the ammonia-water, tar, and oils which are given off when this organic matter is calcined, but the practical realisation of the project has only quite recently been accomplished, and a most unexpected new field of chemical industry thus opened out, through the persevering and sagacious labours of M. Camille Vincent, of Paris.

The following is an outline of the process as carried out at the large distillery of Messrs. Tilloy, Delaune, and Co., at Courrières. The spent-wash having been evaporated until it has attained a specific gravity of 1.31, is allowed to run into cast-iron retorts, in which it is submitted to dry distillation. This process lasts four hours; the volatile products pass over, whilst a residue of porous charcoal and alkaline salts remains behind in the retort. The gaseous products given off during the distillation are passed through coolers, in order to condense all the portions which are liquid or solid at the ordinary temperature, and the combustible gases pass on uncondensed and serve as fuel for heating the retorts.

FIG. 1.

The liquid portion of the distillate is a very complex mixture of chemical compounds, resembling in this respect the corresponding product in the manufacture of coal-gas. Like this latter, the liquid distillate from the spent-wash may be divided into—

1. The ammonia water.
2. The tar.

The ammonia water of the vinasse resembles that of the coal-gas manufacture in so far as it contains carbonate, sulphurate, and hydrocyanide of ammonia; but it differs from this (and approximates to the products of the dry

distillation of wood) by containing in addition methyl alcohol, methyl sulphide, methyl cyanide, many of the members of the fatty acid series, and, most remarkable of all, *large quantities of the salts of trimethylamin.*

The tar, on re-distillation, yields more ammonia water, a large number of oils, the alkaloids of the pyriden series, solid hydrocarbons, carbolic acid, and, lastly, a pitch of fine quality.

The crude alkaline aqueous distillate is first neutralised by sulphuric acid, and the saline solution evaporated, when crystals of sulphate of ammonia are deposited; and these, after separating and draining off, leave a mother-liquor, which contains the more soluble sulphate of trimethylamin. During the process of concentration, vapours of methyl alcohol, methyl cyanide, and other nitriles are given off, these being condensed, and the cyanide used for the preparation of ammonia and acetic acid by decomposing it with an alkali.

Trimethylamin itself is at present of no commercial value, though perhaps the time is not far distant when an important use for this substance will be found. The question arises as to how this material can be made to yield substances capable of ready employment in the arts. This problem has been solved by M. Vincent in a most ingenious way. He finds that the hydrochlorate of trimethylamin, when heated to a temperature of 260°, decomposes into (1) ammonia, (2) free trimethylamin, and (3) chloride of methyl.

By bubbling the vapours through hydrochloric acid the alkaline gases are retained, and the gaseous chloride of methyl passes on to be purified by washing with dilute caustic soda and drying with strong sulphuric acid. This is then collected in a gas-holder, whence it is pumped into strong receivers and condensed.

The construction of these receivers is shown in Fig. 1. They consist of strong wrought-iron cylinders, tested to resist a pressure of 20 kilos. per square centimetre, and containing 50, 110, 220 kilos. chloride of methyl. The liquid is drawn from these receivers by opening the screw tap D, which is covered by a cap C, to prevent injury during transit.

Both ammonia and chloride of methyl are, however, substances possessing a considerable commercial value. The latter compound has up to this time, indeed, not been obtained in large quantities, but it can be employed for two distinct purposes: (1) it serves as a means of producing artificial cold; (2) it is most valuable for preparing methylated dyes, which are at present costly, inasmuch as they have hitherto been obtained by the use of methyl iodide, an expensive substance.

Methyl chloride was discovered in 1804 by MM. Dumas and Péligot, who obtained it by heating a mixture of common salt, methyl alcohol, and sulphuric acid. It is a gas at the ordinary temperature, possesses an ethereal smell and a sweet taste, and its specific gravity is 1.738. It is somewhat soluble in water (about 3 vols.), but much more in acetic acid (40 vols.), and in alcohol (35 vols.). It burns with a luminous flame, tinged at the edges with green, yielding carbonic and hydrochloric acids. Under pressure methyl chloride can be readily condensed to a colourless, very mobile liquid, boiling at -23°C. under a pressure of 760 m.m. As the tension of the vapour is not high, and as it does not increase very rapidly with the temperature, the liquefaction can be readily effected, and the collection and transport of the liquefied chloride can be carried on without danger.

The following table shows the tension of chloride of methyl at varying temperatures:—

At 0° the tension of CH_3Cl is 2.48 atmospheres.				
" 15°	"	"	4.11	"
" 20°	"	"	4.81	"
" 25°	"	"	5.62	"
" 30°	"	"	6.50	"
" 35°	"	"	7.50	"

From these numbers we must of course subtract 1 to obtain the pressure which the vapour exerts on the containing vessel.

As a means of producing low temperatures chloride of methyl will prove of great service both in the laboratory and on a larger industrial scale. When the liquid is allowed to escape from the receiver into an open vessel, it begins to boil, and in a few moments the temperature of the liquid is lowered by the ebullition below -23° , the boiling-point of the chloride. The liquid then remains for a length of time in a quiescent state, and may be used as a freezing agent. By increasing the rapidity of the evaporation by means of a current of air blown through the liquid, or better by placing the liquid in connection with a good air-pump, the temperature of the liquid can in a few moments be reduced to -55° , and large masses of mercury easily solidified. The construction of a small freezing machine employed by M. Camille Vincent is shown in Fig. 2. It consists of a double-cased copper vessel, between the two casings of which the

FIG. 2.

methyl chloride (A) is introduced. The central space (M) is filled with some liquid such as alcohol, incapable of solidification. The chloride of methyl is allowed to enter from the cylindrical reservoir by the screw tap (B) and the screw (S) left open to permit of the escape of the gas. As soon as the whole mass of liquid has been reduced to a temperature of -23° , ebullition ceases, the screw (S) may be replaced, and if a temperature lower than -23° be required the tube (A) placed in connection with a good air-pump. By this simple means a litre of alcohol can be kept for several hours at temperatures either of -23° or -55° , and thus a large number of experiments can be performed, for which hitherto the expensive liquid nitrous oxide or solid carbonic acid was required.

M. Vincent has recently constructed a much larger and more perfect and continuous form of freezing machine, in which by means of an air-pump and a forcing-pump the chloride of methyl is evaporated in the freezing machine and again condensed in the cylinders. This enlarged form of apparatus will probably compete favourably with the ether, and sulphurous acid, freezing machines now in

use, as they can be simply constructed, and as the vapour and liquid do not attack metal and are non-poisonous, and as the frigorific effects which it is capable of producing are most energetic.

The second and perhaps more important application of methyl chloride is to the manufacture of methylated colours.

It is well known that rosanilin or aniline-red, $C_{20}H_{19}N_3$, yields compounds possessing a fine blue, violet, or green colour, when a portion of the hydrogen has been replaced by the radicals methyl or ethyl, and the larger the proportion of hydrogen replaced the deeper is the shade of violet which is produced. Thus we have triethyl rosanilin or Hofmann's* violet, $C_{20}H_{16}(C_2H_5)_3N_3$.

By replacing one or two atoms of the hydrogen of aniline by methyl and by oxidising the methyl anilines thus obtained, Charles Lauth obtained fine violet colours, whilst about the same time Hofmann observed the production of a bright green colouring matter, now known as iodine green, formed during the manufacture of the violet, and produced from the latter colour by the action of methyl iodide.

In order to prepare aniline-green from the pure chloride of methyl, a solution of methyl aniline-violet in methyl alcohol is placed in an iron digester and the liquid rendered alkaline by caustic soda. Having closed the digester, a given quantity of liquid chloride of methyl is introduced by opening a tap, and the digester thus charged is placed in a water-bath and heated by a jet of steam, until the temperature reaches 95° , and the indicated pressure amounts to from 4 to 5 atmospheres. As soon as the reaction is complete the hot water is replaced by cold, and the internal pressure reduced by opening the screw tap of the digester. The product of this reaction heated and filtered, yields the soluble and colourless base, whose salts are green. To the acidulated solution a zinc salt is added to form a double salt, and the green compound is then precipitated by the addition of common salt. By adding ammonia to a solution of the green salt, a colourless liquid is obtained, in which cloth mordanted with tannic acid and tartar emetic becomes dyed of a splendid green.

If rosanilin be substituted for methyl aniline in the preceding reaction Hofmann's violet is obtained. The application of methyl chloride to the preparation of violets and greens is, however, it must be remembered, not due to M. Vincent; it has been practised for some years by aniline-colour makers. M. Vincent's merit is in establishing a cheap method by which perfectly pure chloride of methyl can be obtained, and thus rendering the processes of the manufacture of colours much more certain than they have been hitherto.

The production of methyl violet from dimethyl aniline may be easily shown by heating this body with a small quantity of chloral hydrate, and then introducing some copper turnings into the hot liquid. On pouring the mixture into alcohol, the violet colour is well seen.

In reviewing this new chemical industry of the beet-root vinasses, one cannot help being struck by the knowledge and ability which have been so successfully expended by M. Camille Vincent on the working out of the processes.

Here, again, we have another instance of the utilisation of waste chemical products and of the preparation on a large scale of compounds hitherto known only as chemical rarities.

All those interested in scientific research must congratulate M. Camille Vincent on this most successful issue of his labours.

The Spottiswoode Testimonial.—The Committee appointed to receive subscriptions to present a bust of Mr. William Spottiswoode, Pres. R.S., to the Royal Institution as a testimonial of his valuable services as its Treasurer and Secretary successively, have engaged Mr. Richard Belt as the sculptor.

NOTE ON
VICTOR AND CARL MEYER'S NEW METHOD OF
DETERMINING VAPOUR-DENSITIES.

By GREVILLE WILLIAMS, F.R.S.

A GREAT number of processes for determining vapour-densities have been published during the last few years, but by far the greater number of them have only been used by their inventors, and none of them have entirely superseded the processes of Gay-Lussac and Dumas for determinations at ordinary pressures.

The last process of Victor and Carl Meyer* has, however, had a different fate, and from the moment it was published excited the earnest attention of chemists and physicists. In simplicity and accuracy it leaves nothing to be desired, and it possesses the great merit of being available at all temperatures up to the softening point of glass; and, doubtless, if the apparatus were constructed in metal its range of usefulness would be still further increased. In fact, MM. Victor and Carl Meyer may be congratulated upon having devised a method of determining vapour-densities which will probably supersede all those in use at the present time for ordinary pressures.

Amongst its other merits it can be constructed by any one with the greatest ease with the materials which are to be found in every laboratory.

Having to determine the vapour-densities of two fractions of β -lutidine, supposed to be very nearly pure, I improvised an apparatus for the purpose. In all essential features it resembled that of Victor and Carl Meyer. The glass flask *c*, in the illustration, p. 66, was, however, replaced by an iron tube closed at the lower end, which happened to be in the laboratory. It was charged with aniline. The long neck of the vapour flask, *b*, was cut off two inches below the lateral tube, *a*, and, the two ends being brought close together, were joined by an india-rubber tube; the object being to give the apparatus some flexibility, and lessen the chances of fracture of the tube *a*, which had been drawn out somewhat too finely. These details are merely mentioned to show that, as long as the essential points of the apparatus are preserved, some latitude may be permitted in putting it together. In my first apparatus the funnel *d* was made as directed, but subsequent experience has shown that it is unnecessary, as the small tube is easily closed by an india-rubber stopper without the necessity for enlarging the aperture.

A preliminary experiment was made with water with the following result:—

$$\begin{aligned} S &= 0.0207 \text{ grm.} \\ t &= 13.1^\circ \\ B &= 758.8 \text{ m.m. (corrected.)} \\ w &= 11.1 \\ V &= 26.5 \text{ c.c.} \\ D &= 0.643 \end{aligned}$$

Experiment.	Theory.	Error.
0.643	0.622	+0.021

Two vapour-densities were then taken with β -lutidine—

Boiling-point, 164° .	Boiling-point, 164° to 165° .
$S = 0.0894$	0.0693
$t = 12^\circ$	12°
$B = 761.5 \text{ m.m. (corr'd.)}$	761.5
$w = 10.2$	10.2
$V = 20.0 \text{ c.c.}$	15.5
$D = 3.65$	3.65

Experiment.	Theory.	Error.
3.65 3.65	3.699	-0.049

I attribute part even of this small error to the β -lutidine containing traces of the next lower homologue.

ON THE ACTION OF NUCLEI, &c.

By C. TOMLINSON, F.R.S.

My paper to which Mr. Grenfell refers (*CHEMICAL NEWS*, vol. xxxix., p. 16) was not read in September, 1877, and its object was not "to upset his theories and establish my own." Is it not possible for a scientific man to be anxious only for the truth? That I was so will appear from the fact that Mr. Grenfell showed me some of his experiments, and although I did not agree with his conclusions, while he decidedly opposed mine, I asked him to draw up an account of them for the Royal Society, and I promised to present his paper, which I accordingly did, and it was read and printed in the *Proceedings*.

My object in repeating Mr. Grenfell's experiments was to see whether any fresh hint could be gathered from them. I never once mentioned my own theory; but I gained this useful piece of information, viz., "that supersaturated saline solutions behave differently among themselves and to different bodies under varying atmospheric conditions;" and that "an oil, &c., introduced into the closed flask, as in M. Viollette's and Mr. Liversidge's experiments, may be inactive, while under the other conditions the same oil may be active." I give abundant proof that this is so in a subsequent paper, which Mr. Grenfell does not appear to have seen; while in a third paper the powerful influence of the sides of the vessel in maintaining the state of supersaturation is dwelt upon.

As space is valuable in the *CHEMICAL NEWS* I will not follow Mr. Grenfell in his method of minute criticism, which throws no light upon the question as to what are the precise conditions under which these solutions become solid. Mr. Grenfell says that it is absorption that does the whole work. That is a fair subject for discussion; but I must protest against the general tone of Mr. Grenfell's note, especially that part of it which makes me so silly as not to know the simple conditions under which he conducted his experiments. In such a censure he, unconsciously perhaps, includes such good observers as Löwel, Viollette, and Liversidge, who expressly say that porous bodies, bodies greedy of water and capable of being hydrated, are incapable of determining the solidification of these solutions. I stated in one of my early papers that I do not agree to this, and in a paper which is now being prepared the reasons will be given more distinctly.

In conclusion, I never said or implied that Mr. Grenfell denied the result of the well-known lecture table experiment with Glauber's salts. I may also add that the early observers saw the objections to cotton-wool for closing the flasks, and that I am not so careless as to allow crystals of the salt to exist in the necks of my flasks before making an experiment.

Highgate, N., March 8, 1879.

LARGE CRYSTAL GROWING.

By CHARLES W. QUIN.

WHEN I was a student I was much given to large crystal growing. My great difficulty was to guard against sudden rises in temperature, which generally had the effect of causing the growing crystal to be partially and unevenly re-dissolved. To receive a continually even temperature, after many experiments I hit upon the plan of plunging the beaker containing the growing crystal into the house-cistern, the temperature of the water in which, as I found by trial, never differed by more than 0.5°F. either way day or night. To prevent the solution from becoming exhausted too rapidly I used to immerse it to the depth of half an inch or so a crystal drainer containing a filter-paper full of the salt to be crystallised, so that a constant stream of strong solution was continually descending on the growing crystal.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, March 6, 1879.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

AFTER the announcement of visitors, confirmation of minutes, &c., the following certificates were read for the first time:—F. A. B. Jewson, T. H. Walker, W. E. Blythe. The list of Officers proposed by the Council was then read from the Chair.

The PRESIDENT then called on Mr. G. ATTWOOD to read a paper "*On the Quantitative Blowpipe Assay of Mercury.*" The author divides compounds to be assayed into three classes. Class A, containing metallic mercury, cinnabar, tiemannite, suboxide, protoxide, and mixed sulphides. Class B, calomel, corrosive sublimate, and iodide of mercury. Class C, amalgams of gold, silver, copper, lead, zinc, tin, &c. Class A.—10 to 20 grains of the ore, finely powdered and passed through a sieve, 2000 holes to the linear inch, are mixed with 5 to 10 times their weight of powdered litharge and distilled over a spirit-lamp in a small glass retort, $1\frac{1}{4}$ inches long and $\frac{1}{2}$ inch in diameter. To this retort is fitted by means of a cork a glass tube, slightly curved, $2\frac{1}{2}$ inches long, and $\frac{1}{4}$ ths of an inch in diameter. The end of this tube dips under water contained in a small porcelain crucible. The operation lasts only a few minutes. The mercury is carefully collected from the glass tube and crucible. The retort is broken up and its contents carefully powdered and examined by a lens for mercury. The globules are then united by gently warming under water, and the dry mercury weighed. Class B.—A quantity of the finely powdered ore, equal to 10 grs., is mixed with three times its volume of oxalate of potash and one volume of cyanide of potassium. The apparatus closely resembles that used in class A, but the retort has a small bulb. Class C.—These amalgams are sometimes powdered with difficulty, and it is often advantageous to add a known weight of pure mercury, so as to render them semifluid before distilling. 10 to 30 grs. of the amalgam are usually taken for an assay. A turned steel retort is used for distillation, which is effected in a small charcoal furnace heated by a blowpipe flame; the head of the retort is accurately ground to fit over the body. The retort including the cup and cap is 1 inch high; the neck of the cap is 2 inches long. The paper contains full-size illustrations of the different retorts, &c., which are made by Casella. The author has had much experience, and states that most accurate results can be obtained with the above apparatus.

The next paper was read by Mr. J. W. THOMAS. "*On some Points in the Analysis of Combustible Gases and in the Construction of Apparatus.*" In 1874 the author noticed that when a small quantity of marsh gas was mixed with about three times its volume of oxygen and rarefied until the pressure was 160 m.m. no explosion took place; similarly when mixed with twice its volume of oxygen under a pressure of 130 m.m. the spark did not ignite the mixture. It soon became evident that the cooling effect of the walls of the eudiometer was the chief agent in modifying the force of the explosion. It was also noticed that the expansion of a gas to twice its volume lessened the force of the explosion to a greater extent than the addition of an equal volume of inert gas at the initial pressure. The author accordingly made estimations with marsh gas and hydrogen, using nearly the theoretical quantities of oxygen and a pressure of 160 to 170 m.m., and found that perfectly accurate results were obtained, whilst the safety of the eudiometer tube was not in the least endangered. The author then proceeds to point out the errors which creep in when the long (800 to 900 m.m.) eudiometer tube of Frankland and Ward's or

McLeod's apparatus is used, and proves that the sensitiveness of the apparatus depends on the length of the pressure tube above the top of the eudiometer tube. With the old method of introducing a large excess of oxygen in order to moderate the violence of the explosion, this long eudiometer tube was necessary to contain the large quantity of gas introduced. On the other hand, to lengthen the pressure tube would render it unwieldy from its great length, so that with the old method of introducing a large excess of oxygen the relative lengths of the pressure and eudiometer tubes must remain unaltered; but by employing the reduced tension method proposed by the author, and in which only the theoretical quantity of oxygen required has to be introduced, the necessity for such a long eudiometer tube is obviated. The author, therefore, has shortened the eudiometer tube to about 500 m.m., retaining the original length of the pressure tube, and finds that the apparatus has gained in delicacy and is still sufficiently large for all substances. The next modification introduced by the author is the substitution of a steel block with a three way steel tap for the glass taps connecting the barometer tube, eudiometer tube, and pressure bottle. The tubes are fixed and held tight in the steel block by india-rubber rings, screwed down by means of steel collars. Flexibility and absolute tightness are thus secured. As regards the steel tap the author has had no difficulty in keeping it perfectly tight; the three ways are gouged out on the surface of the tap and are not bored. The use of the steel plates connecting the eudiometer and laboratory tubes has been abandoned, and a hollow glass tap substituted, which is so bored that the tubes can be washed out. The mercury trough is made movable by an ingenious mechanical arrangement. The supply of water to keep the apparatus at a constant temperature is brought in at the top of the barometer tube; the exit is at the bottom, and a syphon arrangement is added to ensure a thorough mixing of the water round the top of the eudiometer tube. The little windlass has been modified so that it can be worked with one hand. In conclusion the author gives details as to the management of a gas analysis with the modified method and apparatus; a drawing of the latter accompanies the paper.

Prof. FRANKLAND complimented the author on the ingenuity displayed and the success achieved in his paper. At the first mention of the return to a use of the steel stopcock he must confess that he had almost shuddered. Twenty-five years ago when glass stopcocks were a luxury these steel taps constituted a never-ending source of annoyance. After a week's work a leak almost always occurred, which necessitated a prolonged and careful grinding. This might be due to the fact that the tap was made of cast-iron and the plug was bored. The method of exploding gases with almost theoretical quantities of oxygen was a decided step in advance. The shortening of the eudiometer tube and the increased sensitiveness thereby attained seemed to him also most important improvements. He would like to ask Mr. Thomas how the bursting of the flexible tube connected with the pressure bottle was obviated. All plans that he had tried had ultimately failed (winding tape, tubing with canvas in it, &c.).

Dr. WRIGHT suggested that the tubing should be coiled round with bell-wire.

Prof. McLEOD said that a plan which answered very well was to bind the tube with tape, and cover that with sheet india-rubber to prevent contact of the tape with potash, &c. He had been much struck with the success with which Mr. Thomas had used the theoretical quantity of oxygen without fracturing the eudiometer. In the old apparatus the difficulty was not so much to keep the steel tap tight as to make a tight cement joint between the block and the glass tubes.

Mr. HART suggested that the india-rubber tubing should be wound with tape soaked in glue containing bichromate of potash. On subsequent exposure to light a compound was formed unattacked by acids and alkalis.

Dr. ARMSTRONG had used a gas apparatus made after Mr. Thomas's model with great success. His stopcock was bored. The leakage of the old stopcocks might be due to corrosion by resin cerate. Bullocks' fat was most suitable for lubrication (Prof. Frankland stated that melted india-rubber was always used, not resin cerate, for the taps). He suggested that the mechanism employed by Mr. Thomas for shifting the mercury trough caused much vibration: he had used a small hydraulic lift. If the india-rubber tube were covered with double tape sewed longitudinally no difficulty was experienced.

Mr. THOMAS, in reply, pointed out that his steel tap was of a much larger size than the old one. In answer to Dr. Armstrong, no vibration was caused by the turning aside of the mercury trough.

The next paper was read by Mr. J. M. THOMSON, "*On the Action of Isomorphous Salts in Exciting the Crystallisation of Supersaturated Solutions of each other, and some Experiments on Supersaturated Solutions of Mixed Salts.*" In this paper the author communicates the results of more than 400 observations. The following are given as the general results to be deduced from the experiments. The results of Gernez (*Ann. Sci. de l'Ecole, norm. sup.*, 1861) have been confirmed and extended, showing that truly isomorphous bodies act as exciting nuclei in inducing the crystallisation of supersaturated solutions; that mere form alone does not render the body active to a supersaturated solution of a salt isomorphous with the nucleus; but that it is necessary for the nucleus to possess an identical chemical structure. Thus, cubes of iron pyrites and octahedral crystals of magnetite are inactive to alum solutions. In the case of mixtures of solutions two series of results were experienced in the same solution:—A. When the mixture consists of two salts not isomorphous—(1) Sudden crystallisation may commence, spreading, however, gradually through the solution, on the addition of a nucleus, causing a deposition of the body belonging to the nucleus only. (2) That when sudden crystallisation takes place, causing the deposition of both salts, there is a preponderance of the salt of the same nature as the nucleus. (3) That the nucleus may remain growing slowly in the solution, becoming increased by a deposition of the salt of the same nature as the nucleus. B. When a mixture consists of two isomorphous salts—(1) Sudden crystallisation may occur, giving a deposition of both salts apparently in the proportions in which they exist in solution. (2) That when slow crystallisation takes place the nucleus increases by a deposition of the least soluble salt, showing that in mixed supersaturated solutions a gradation of phenomena may be experienced passing from those shown in the crystallisation of a true supersaturated solution to those shown in the crystallisation of an ordinary saturated solution. The experiments were chiefly made as follows:—The saturated solution to be used as a nucleus was placed either in a bulb-tube or a tube bent at its lower end into a double U (as used by Liversidge). The solution was then boiled, and the tube plugged with cotton-wool. The supersaturated solution was introduced into a small flask. The tube with nucleus solution is plugged tightly into the neck of the flask, and the solution boiled. When cold, the nucleus solution is caused to crystallise, and lowered so that at first the glass only touches the solution; this produced uniformly negative results. On bringing the crystals in contact by breaking the bulb or lowering the U-tube crystallisation commenced if the nucleus was active. The author is continuing his experiments, and promises a further communication on the subject. The substances already experimented with include—Magnesium sulphate, $7\text{H}_2\text{O}$, to which zinc, nickel, cobalt, iron sulphates with $7\text{H}_2\text{O}$ are all active; sodium sulphate with 10 or $5\text{H}_2\text{O}$ being inactive; sodium sulphate and seleniate, $10\text{H}_2\text{O}$, are active to sodium sulphate solution, $10\text{H}_2\text{O}$. Chrome and iron potassium alums with $12\text{H}_2\text{O}$ are active to the ordinary potash alum, &c.

The PRESIDENT remarked how various were the conclusions which had been arrived at concerning the crystalli-

sation of supersaturated solution by different experimenters. Mr. Thomson's researches had modified the difficulties which existed as to the theory that the cause was the introduction of a crystal of the same salt, by pointing out that a similar salt would also act as a nucleus, and the method might prove an accurate means of determining whether two bodies of similar, were really of identical, chemical composition or not.

Dr. WITT, in reply to a question put by Mr. Thomson, said that supersaturated solutions were of frequent occurrence in the salts of the aromatic substances, disulpho-derivatives of benzene, the acetates of the different rosanilins, &c. He asked whether the phenomena of supersaturation were included by Mr. Thomson in the same class as those of supersaturation.

Prof. HARTLEY suggested that the crystallisation of one salt out of a mixture, by introducing a nucleus active to it but inactive to the other salts, might be very useful for separation on the manufacturing scale.

Mr. GROSJEAN said that Crace-Calvert had thus crystallised carbolic acid from a mixture of that substance and cresolic acid.

Mr. THOMSON did not think any strict line could be drawn between supersaturation and supersaturation.

The SECRETARY then read a paper by WATSON SMITH, "*On the Isomeric Dinaphthyls.*" This communication is a continuation of the author's previous work. The immediate objects of the present investigation were—(1) To prepare a quantity of the α - α -dinaphthyl (melting-point 154°) by Lossen's method, in order to compare it with the body previously obtained by the author in yellowish plates (m.p. 147°). (2) To examine the crude product obtained by Lossen to see if it contains besides the α - α -dinaphthyl an appreciable quantity of the other two dinaphthyls. (3) To prepare sufficient quantities of the three isomers in a completely pure condition, and to determine their vapour-densities. (4) To discover further reactions in which dinaphthyl is formed, so as to find out, if possible, so much about the conditions of its formation as would lead to a method of preparation more easily carried out and giving a larger yield of product than the present method. (1) The author prepared the α - α -dinaphthyl, and found that it melted at 147° , but by further boiling with animal charcoal in petroleum spirit, colourless crystals were obtained, melting at 154° to 155° . (2) The β - β - and the α - β -dinaphthyls could not be detected. (3) The pure substances were obtained, and their vapour-densities determined by V. Meyer's new apparatus with great facility; a lead-bath and nitrogen atmosphere were used. β - β -dinaphthyl, m.p. 187° , v.d. 8.73; α - α , m.p. 154° , v.d. 8.67; α - β , m.p. 76° , v.d. 8.78; calculated v.d., 8.77. In the fourth part the author has investigated the action of carbon tetrachloride, chloroform, carbon disulphide, bromo-naphthalene on naphthalene. He has further investigated the reactions which take place when a mixture of bromo-naphthalene and naphthalene are passed over heated soda-lime, lime, ferric oxide, and silver.

The Society then adjourned to March 20, when the following papers will be read:—"On Perplumbic Ethide," by E. Frankland and A. Laurance; "On the Decomposition of Water by certain Metalloids," by C. F. Cross and A. Higgin; "On the Volumetric Determination of Chromium," by W. J. Sole; "The Production of the Higher Oxides of Iron, Chromium, Manganese, and Bismuth," by W. Foster.

PHYSICAL SOCIETY.

Ordinary Meeting, March 8, 1879.

Prof. W. G. ADAMS, President, in the Chair.

Dr. HURST and Mr. Jacob were elected Members.

Prof. AYRTON brought forward a new theory of terrestrial magnetism, originated by himself and Prof. Perry, of the Imperial Engineering College, Japan. It is well known

that metal cages act as screens against induction in the case of static electricity or electricity at rest, and hence Clerk Maxwell, at the British Association meeting for 1876, suggested that no earth connection was necessary for lightning-conductors, since a cage would be sufficient. But dynamic electricity is different from static in this respect, and Profs. Ayrton and Perry found that even a thick block of copper will not screen a coil of wire from the induction by a current flowing in a neighbouring one. Some experiments of Dr. Muirhead, not yet published, would seem to favour the view that a current is a series of intermittent changes of potential, and that the inductive effect was due to a difference in the epochs of the currents in the two coils. It was found by Helmholtz that a quantity of static electricity in mechanical motion performs work conversely. Mr. Crookes finds that the stream of molecules from a -pole *in vacuo* is electrified and may be deflected by a magnet. It is upon that fact that Profs. Ayrton and Perry have based their theory, which is easily explained by supposing the earth to be an isolated sphere with a static charge residing on its surface. Then, since each electrified particle at the surface will be moving relatively to a point in the interior, it follows that the interior must be magnetic. The theory is independent of the substance of the interior; but in order to simplify the working the authors treated the case of a solid iron ball, and curiously enough arrived at the result expressed by Biot's law for the distribution of magnetism on the surface of the earth:—

$$I = M \sqrt{1 + 3 \cos^2 \theta}.$$

And, similarly, they found that if the earth were electrified to the potential of 10^6 volts. relatively to interplanetary space, its magnetisation would be as it is. If the earth were alone in the universe, then, by this theory, it would have its own magnetic state by virtue of its electric charge and axial rotation. If other bodies in the universe, however, had their magnetic states too, these would influence the earth's, and hence we should have terrestrial tides and storms of magnetic force, such as are known to exist, as, for instance, when changes take place in the sun's atmosphere by approach of planets and other causes. Lastly, the iron in the interior of the earth may give it a certain amount of coercive force, but the theory does not rest on this.

Dr. J. HOPKINSON then read an account of some experiments with the quadrant electrometer, which showed that Clerk Maxwell's formula for the sensibility of the electrometer,—

$$(A - B) \left(C - \frac{A + B}{2} \right),$$

where A and B are the potentials of the two pairs of quadrants, and C the potential of the needle, only holds good when C (the charge of the jar or needle) is less than 200 Daniell elements. Above that a different law appears to hold. Dr. Hopkinson also remarked that any degree of low sensibility down to zero could be got from the electrometer by connecting a condenser to each pair of quadrants, and adjusting their capacities.

Mr. F. D. BROWN described his apparatus for maintaining constant temperatures and pressures. A constant temperature can be obtained if the pressure can be kept constant. The vessel in which the constant pressure is desired communicates with an air-pump by a pipe in which a movable tap or valve is placed. By opening or closing this tap the pressure is regulated. This is effected by an electric clutch arrangement. A mercury anemometer sends a positive or negative current from a battery through the clutch according as the pressure is too high or low, and this current actuates the clutch to close or open the valve. The clutch consists of an axle driven by a turbine to get power to work the valve, and the current, by means of electro-magnetism, connects the tap to the axle, which then opens or closes it as the case may be. In this way a pressure varying no more than one-fifth millimetre each way can be obtained.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, February 18, 1872.

J. P. JOULE, D.C.L., LL.D., F.R.S., &c., President, in the Chair.

JAMES BOTTOMLEY, B.A., D.Sc., and RICHARD S. DALE, B.A., were appointed Auditors of the Treasurer's accounts. "On a Chemical Investigation of Japanese Lacquer, or 'Urushi,'" by SADAMU ISHIMATSU. Communicated by Professor ROSCOE, LL.D., F.R.S.

During a few months last year I had the opportunity of examining roughly into the nature of "Urushi," in the Laboratory of Tokio University.

The specimen of lacquer which I had under my examination was obtained from Kuyemon Nakamuraya, in Tokio, a large lacquer merchant.

It is a milky juice of pale grey colour, and gives out a certain kind of poisonous volatile gas. Some persons are terribly attacked by this poison, producing a great swelling where the acid comes in contact. During my examination in the laboratory one of the apparatus keepers was terribly attacked by this gas, producing ugly swellings all over the face. He told me at the time it was exceedingly itchy. By using the solution of chloride of sodium, carbonate of soda, acetate of lead, &c., he was said to have recovered within a week. This poison acts only on certain persons. I had to work with it for many days, yet never had any attack of the kind nor felt any uneasiness from it.

It has a sweetish characteristic smell, and has an irritating taste. It burns with very luminous flame, evolving dense black smoke like oil of turpentine.

It is to a great extent soluble in benzol, ether, absolute alcohol, &c., leaving behind a blackish grey residue in which gum was found.

Lacquer on exposure to the atmosphere rapidly loses its weight, and at the same time blackens on its surface; although this loss is different in different specimens, yet on the average of those which I have examined it seems to vary from 25 to 37 per cent.

When the lacquer is exposed to the action of sunlight in hermetically sealed vessels in the atmosphere or in carbonic acid, blackening does not take place, but a large quantity of moisture collects on the sides of the vessel.

The loss of weight in the atmosphere is almost if not entirely due to the escape of water, with a minute quantity of carbonic acid which may be formed by the oxidation of some organic compound existing in the lacquer. The attempt has been made to estimate the relative amounts of carbonic acid and water; yet it was not successful at the time, being too difficult, and it must be left open to some future investigation.

It is by many supposed to be due to the combined action of light and air that the blackening of lacquer in the air takes place; but this seems to be erroneous from the following experiments:—First. I made a square box which had a well fitting sliding door, and the inside of which was made perfectly black, so that practically no light is permitted to enter. In it was placed a small quantity of lacquer at dark, and the door closely shut. On looking at it the next morning it was observed that the lacquer had turned perfectly black, proving that it is not the light that blackens the lacquer.

Second. The bottle in which I kept my lacquer for more than three months during my examination was exposed to the incident light of the laboratory. The surface of the lacquer was turned perfectly black, forming a wall as it were; while those portions which were in contact with the sides of the bottle, which receive as much light as if there were not any glass sides before it, were not at all blackened. This phenomenon is just complementary to the first one, proving that the blackening in the atmosphere is in all probability due to the oxygen of the air, but not the light alone, nor the combined action of light and air.

The lacquer when distilled with water gives a colourless distillate which is slightly acid to test-paper, and the attempt has been made to examine the acid, but not successfully on account of too minute quantity of the substance evolved. Distillation by itself and in a current of steam was tried also, but the results in both cases were the same as the first one. Lastly, distilled with a small quantity of dilute sulphuric acid, to aid the substance to distil over, into sugar of lead, scarcely any precipitate was obtained.

Lacquer mixes with any kind of fixed oil in all proportions; hence oil is often added as adulteration, but sometimes it is purposely added to increase its mobility.

The specimen of lacquer which I examined consisted of the following three substances:—

	I.	II.
Part soluble in absolute alcohol (resin)	58.24	58.23
Gum	6.34	6.30
Residue	2.24	2.30
Moisture and other volatile matter	33.175	33.170
	100.00	100.00

As I have already mentioned, the lacquer loses its weight very rapidly when exposed to the atmosphere. For the above determination I weighed out each time samples from well stoppered bottles, and determined the weight by difference. Then this was treated with absolute alcohol and the filtrate evaporated to small bulk and dried in an air-bath at 100° C. until the weight remained constant. This is put down as the part soluble in alcohol in the above analysis. The residue was then treated with hot water, and the filtrate evaporated and dried at 100° and weighed as gum. The residue, after the gum had been removed, was then washed, and dried on weighed filter at 100° C., and weighed as residue. The moisture and other volatile matter were of course determined by the difference.

The estimation of the amount of part soluble in alcohol, after the lacquer had been exposed to the sunlight in open vessel for some twenty or thirty days, shows that the soluble part increased up to 72.82 per cent. This number, when calculated for the substance to have lost 28 per cent moisture and other volatile matter during exposure, then equals 58.3 per cent, which is nearly equal and practically the same as the analysis previously given; hence there seems to have been no material change in the amount of matter soluble in alcohol. Now the perfectly dried lacquer, after being finely powdered, was dried at 100°, and analysis gave:—

Part soluble in absolute alcohol	18.07
Gum	3.63
Residue	78.30
	100.00

Altogether, from this analysis, the residue being increased, the lacquer seems to have undergone some change; but possibly this is owing to the fact that the alcohol as well as water seem to have had less complete access to the material.

Thus the "Urushi" consists of three principal constituents, (1) a resinous part soluble in alcohol, (2) gum, and (3) residue. Although there are, in addition to these, water and volatile matter, as they go away sooner or later before it is used they are not properly called the constituents.

(1) Part soluble in alcohol (resin) seems to be the principal portion, and has a smell like ordinary lacquer, but it never dries as the original does. It is brownish black, and slightly sticky to the touch. When treated with potash solution it forms a bluish black precipitate, but nothing is obtained on addition of sulphuric acid to the filtrate.

When boiled with hydrochloric acid the resin is transformed into a substance elastic while hot, something like the mass obtained when heated sulphur is dropped into

cold water. When boiled with nitric acid nitrous fumes are given out, and the mass gradually becomes yellow, and finally a beautiful orange coloured mass was obtained. This mass was washed with hot water several times, and then treated with absolute alcohol. The mass was to a great extent soluble in the alcohol, leaving behind a small quantity of a yellowish body (which I think to be part not sufficiently acted upon by the acid). This alcoholic extract forms a beautiful yellow precipitate with both nitrate of silver and acetate of lead. I took a quantity of alcoholic extract, precipitated it with acetate of lead, and the precipitate was thoroughly washed with absolute alcohol, and then decomposed by means of dilute sulphuric acid. (It might be better to decompose this salt with sulphuretted hydrogen, but we cannot do so on account of reducing action of this gas.) The mass was dissolved again in absolute alcohol, then separated from sulphate of lead.

Now then this separated alcoholic extract was again precipitated by sugar of lead, and, after filtering and washing, the precipitate was dried partially in an air-bath, and carried under the receiver of an air-pump and dried over sulphuric acid.

This lead salt exploded when heated. The amount of lead was estimated as oxide by igniting it with nitric acid, and the salt was subjected to organic combustion. Nitrogen was determined by Dumas's method.

The following numbers were obtained as the mean results:—

Carbon	26.93
Hydrogen	4.11
NO ₂	18.44
PbO	47.42
Oxygen	3.10
	100.00

Now I prepared the silver salt of the same, and obtained 18.5 per cent of silver as the result. It seems to give no help as to the formula of this body.

As such was the case, I took alcoholic extract of the original lacquer and precipitated it with acetate of lead, and after requisite purification and drying the precipitate was analysed. Lead determined as before.

The following is the mean of two experiments which I was only able to try:—

Carbon	50.450
Hydrogen	5.705
PbO	3.775
Oxygen	40.070
	100.000

(2) The gum is soluble in cold as well as in warm water. It has no smell, almost no taste; it has a yellowish or rather brownish colour, and is of a non-crystalline body. It is quite insoluble in alcohol.

On subjecting this substance to organic analysis I got the following percentage of hydrogen, carbon, and oxygen:—

	I.	II.
Carbon	41.20	41.45
Hydrogen	6.51	6.58
Oxygen	52.29	51.97
	100.00	100.00

These analyses yield a formula approximating to the composition of common gum.

(3) The residue is, I think, nothing more than the mixture of cellulose, bark, dust, &c.

In concluding my paper I must say that I am not at all satisfied with my present analyses, but I thought it might be of some interest to some of you from the point that, although the varnished articles from this juice are so celebrated, yet, as far as I am aware, this is the first analysis of the kind that has been heretofore attempted, and might be of some use to those who are interested upon this subject.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—Judging from the erroneous statements contained in a letter signed "A Disgusted Promoter," in the CHEMICAL NEWS, vol. xxxix., p. 102, it would seem either that all the notices and papers sent to Members had miscarried in his case, or that the writer, although on the original Committee, as he intimates, is not actually a Fellow of the Institute.

So far from it being true "that the executive dared not publish a report of the meeting because nearly all the speakers upheld the system of giving certificates for advertising purposes," a report of the Conference on Trade Certificates has been printed for the use of Members. Again, the writer says—"In a few days' time a second conference will be held, at which the subject of the 'Adulteration of Food and Drugs' will be discussed." If he were actually a Fellow of the Institute he ought to know that that conference took place a fortnight ago, and that the notice sent out stated the subject to be "Adulteration of Articles of Food," and not "Adulteration of Food and Drugs." If, however, "A Disgusted Promoter" is really a Fellow of the Institute, and through some extraordinary and unfortunate coincidence all the notices, &c., have miscarried in his case, I should feel much obliged if he would communicate with me on the subject, and I will endeavour to ascertain the cause.

In conclusion, I may say that although the Council welcome open and fair criticism of their proceedings by independent Members, an anonymous letter recommending the Fellows not to pay their subscriptions can scarcely be considered as of that nature.—I am, &c.,

CHARLES E. GROVES, Secretary.

Somerset House Terrace, W.C.

CRYSTALLISATION OF PHOSPHORUS.

To the Editor of the Chemical News.

SIR,—Seeing Mr. Whewell's interesting contribution on farina in the CHEMICAL NEWS (vol. xxxix., p. 97) reminds me of a question I have often wished to ask. Having been now interested for some years in the crystallisation of phosphorus, anthracene, &c., *in vacuo*, I have eagerly looked for further details of Mr. Whewell's experiments (vol. xxviii., p. 205). Mr. Whewell there states that if the phosphorus is heated and spread over the sides of the tube "beautiful colourless crystals" will be obtained, "which will be slightly red." He also states that having made some of these peculiar crystals he sent them to a well-known mineralogist, who promised to examine them. Is Mr. Whewell in a position now to give us more information concerning them or even the well-known mineralogist's report.—I am, &c.,

GEORGE E. DAVIS.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 7, February 17, 1879.

Researches on Electric Fishes; Characters of the Discharge of the Gymnotus; Effects of the Discharge of the Torpedo Received in a Telephone.—E. J. Marey.—Physiologists have been struck with the analogies presented by a muscle and the apparatus of electric fishes. These two kinds of organs, both subject

to the will and provided with nerves for centrifugal action, have further a very analogous chemical composition, and even some points of structural resemblance. These views, put forward before physicists had developed the theory of the correlation of forces, were necessarily very vague. It might even be conceived that in the living organism, as well as in our physical instruments, analogous conditions might produce either mechanical work or electricity. Having found that muscular acts are complex, *i.e.*, that a muscle in tetanus or in contraction executes a series of minute successive movements, which the author calls *shocks*, which accumulate to produce muscular contraction, he has examined the discharge of the torpedo, and found there a similar complexity. Having passed this discharge through an electro-magnetic tracing apparatus he found that it was made up of minute shocks, which recur at the rate of 150 in a second. Cold reduces the rate alike of the muscular and electric shocks, whilst heat acts inversely. Hence the author concludes that these two functions are really homologues. The gymnotus gave similar results to those of the torpedo. The latter fish, when connected with a telephone and slightly excited, produced a very short croaking. If a prolonged discharge is occasioned by pricking the electric lobe of the brain the sound produced lasts three or four seconds and in tonality borders upon *mi* (165 vibrations).

Does the Didymium of Samarskite Differ from that of Cerite?—Lecoq de Boisbaudran.—The author concludes that both give alike the three blue rays 482.2, 475.8, and 469.1.

New Spectral Rays in Substances Extracted from Samarskite.—Lecoq de Boisbaudran.—On examining with the spectroscope both by absorption and by means of the electric spark, the products of his operations on the mixture of earths from samarskite, the author has observed rays or bands not to be referred to any element formerly known, and not corresponding to the descriptions of the spectra of the earths recently announced by MM. Delafontaine, L. Smith, Soret, and De Marignac. These new rays of absorption and emission seem to belong to one and the same body. The emission spectrum is composed of four bands shaded towards the left and formed of narrow rays, the strongest of which is the most refrangible and forms the right margin of the band. The absorption spectrum comprises two strong bands in the blue, and several rays of less importance in the green. The metal which yields these new spectra is precipitated as a double potassic sulphate along with didymium; its simple sulphate is rather less soluble than that of didymium; its oxalate is precipitated along with didymium, but ammonia separates the oxide of the new metal before that of didymium.

Unequal Propagation of Light Polarised Circularly in Bodies Submitted to the Action of Magnetism According to the Direction of Magnetisation and of the Luminous Vibrations.—H. Becquerel.—The phenomena of magnetic rotatory polarisation is accompanied, like natural rotatory polarisation, with a variation in the speed of propagation of two luminous rays polarised circularly in an inverse direction.

Compressibility of Gases at High Pressures.—E. H. Amagat.—Under a pressure of 430 atmospheres the volume of a gas is nearly $\frac{1}{2}$ greater than that which is deduced from the law of Mariotte.

Improvements in Harrison's Electric Lamp.—E. Ducretet.—This paper is not intelligible without the accompanying figure.

Relations which Connect the Tetric and Oxytetric Acids and their Homologues to Succinyl, Malyl, and other Radicles of the Bibasic Acids.—M. E. Demarçay.—The nature of the radicle of oxytetric acid is that of malyl, the radicle of malic acid.

Bromo-citraconic Acid.—E. Bourgoïn.—Not adapted for useful abstraction.

Les Mondes, Revue Hebdomadaire des Sciences.

No. 8, February 20, 1879.

A Last Word on Matter.—E. Lafond.—“I announce to our friends that *matter is known*. I know now what it is. I will confine myself to telling you that it is essentially the *negation of being*! *Inanis et vacua*. This is a great step for science and the coronation of my system. We float in God, like the fish in water. The latter knows its element; man denies his. Which is the fool?”

Improvement in Bunsen's Battery.—F. Lefebure.—The oxidation of the exterior surface of the zincs contributes nothing to the liberation of electricity, so it may be safely covered with varnish, thus reducing the consumption of zinc by one half.

Poisonous Properties of Phenic Acid.—According to M. E. Küster the surgical use of this acid is not unattended with danger. He has collected twenty-six cases of evident poisoning, more or less severe. He recommends thymol, salicylic acid, or dilute solutions of zinc chloride (8 per cent) as antiseptic dressings.

An Unfortunate Pharmacist.—A French pharmacist has been fined 625 francs for illegally practising medicine. He had sold a few sous worth of “white water” (Goulard's lotion) for the treatment of a burn. The patient died of tetanus and the pharmacist was accused of poisoning, but finally escaped with the penalty above mentioned.

The Birth-rate in France.—Dr. Bertillon calculates that France capitalises $1\frac{1}{2}$ milliards yearly by reason of its small birth-rate, whilst Germany loses $1\frac{1}{2}$ milliards yearly by the rapid increase of its population.

Preservation of the Eggs of the Silk-worm in Different Gaseous Media.—G. Luvini.—The author has preserved the eggs of the silk-worm in hydrogen, carbonic acid, oxygen, and nitrogen for about three months. Those which had been kept in carbonic acid and in nitrogen after removal hatched well and gave an almost complete yield.

Verhandlungen des Vereins zur Beförderung des Gewerbfleisses. Part 1, January, 1879.

This part contains no chemico-technological matter.

MEETINGS FOR THE WEEK.

- MONDAY, 17th.**—Medical, 8.
— Society of Arts, 8. “Dwelling Houses Their Sanitary Construction and Arrangements,” by Dr. W. H. Corfield, M.A. (Cantor Lectures.)
— London Institution, 5.
TUESDAY, 18th.—Civil Engineers, 8.
— Royal Institution, 3. “Animal Development,” Prof. Schäfer.
— Zoological, 8.30.
— Society of Arts, 8. “Africa, a Paramount Necessity for the Future Prosperity of the Leading Industries of England,” by James Bradshaw.
WEDNESDAY, 19th.—Society of Arts, 8. “Economical Gardens for Londoners,” by W. Mattieu Williams, F.R.A.S., F.C.S.
— Meteorological, 7.
THURSDAY, 20th.—Royal, 8.30.
— Royal Institution, 5. “Sound,” Prof. Tyndall.
— Royal Society Club, 6.30.
— Chemical, 8. “On Perplumbic Ethide,” by E. Frankland and A. Lawrance. “On the Decomposition of Water by Certain Metalloids,” by C. F. Cross and A. Higgin. “On the Volumetric Determination of Chromium,” by W. J. Sole. “The Production of the Higher Oxides of Iron, Chromium, Manganese, and Bismuth,” by W. Foster.
— London Institution, 7.
— Zoological, 4.
FRIDAY, 21st.—Royal Institution, 9. “Denotating Agents,” by Prof. Abel.
SATURDAY, 22nd.—Royal Institution, 3. “Etching,” by Mr. Seymour Haden.

THE PATENTEES' MANUAL.

A Treatise on the Law and Practice of Letters Patent, especially intended for the use of Patentees and Inventors.

BY

JAMES JOHNSON, ESQ.,
Of the Middle Temple, Barrister-at-Law, and

J. HENRY JOHNSON,
Solicitor and Patent Agent, Assoc. Inst. C.E. 47, Lincoln's Inn Fields, W.C., and Glasgow.

This Edition, much enlarged, gives a practical reference to every reported case of importance, and contains all the information on the law and practice of Patents Inventors and Patentees can require.

The Appendix contains the Statutes and Rules, and a summary of the Laws of all Foreign States and British Colonies.

London: LONGMANS and CO.

ORGANIC MATERIA MEDICA. By DR. MUTER.

Analytical Chemists will find this a concise and yet complete book of reference for the isolation and examination of the active principles of drugs. Special appendix on the microscopic characters of the starches in food and drugs. Copious index and qualitative courses or resins, &c.

Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, S.E., and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox.

ROYAL POLYTECHNIC.—BUNYAN'S
PILGRIM'S PROGRESS, illustrated by Dissolving Views and Scenic Tableaux. The allegory has been adapted by Dr. AVALLINO, and is read by Mr. OSCAR HARTWELL.—**THE ELECTRIC LIGHT**, by Mr. J. L. KIWO.—**VOYAGES IN THE AIR** (a pictorial and experimental lecture), by Mr. T. C. HAWTHORNE.—**THE STEAM ENGINE**, its origin, history, and present perfection; and GAS, what it does and what it can do; both experimental and highly interesting lectures, by Mr. J. L. KIWO.—In preparation, a dioramic lecture on the ZULUS and their Country, by Mr. W. R. MAY.—Admission 1s.; after 8.45 p.m. (including reserved Stalls), 1s.; Schools and Children under 10, 6d. Open from 12 till 5, and from 7 till 10.

THE CHEMICAL NEWS.

Vol. XXXIX. No. 1008.

NEW PATENT LEGISLATION.

AMONG the many remedies proposed for the present depressed condition of British manufactures it is more than strange that such an immense majority overlook the simplest means—the encouragement of invention by giving increased facilities for obtaining and retaining patents. When we consider what we owe to invention in the past; when we further reflect that our most formidable manufacturing rivals possess a patent law in most points superior to our own, and that they ascribe to this patent law a very great share in their rapidly-growing industrial prosperity; when we reflect on these things, it does indeed seem to us surprising that patent law reform is not recognised as *the* question of the day.

Our present patent system, though possessing certain meritorious points, labours under very serious drawbacks. Its capital defect is the exorbitant cost of obtaining and upholding a patent, which amounts to £175 in stamp duties alone. It is very true that of this sum £50 are payable before the end of the third and £100 before the expiration of the seventh year respectively. But this plan of periodical taxes, non-payment of which at once renders the patent void, is fatal to the most essential element in the value of every kind of property, viz., security. It is not to be expected that manufacturers will pay a royalty to work a patent which if they only wait for a year may perhaps be thrown open to the world.

If we turn to the United States we find that there one payment of 35 dollars secures to an inventor the absolute right to his ideas for a term of seventeen years. Can we wonder if under such a system working men spend their leisure in trying to devise some improvement, some new "notion," of a useful character, and that foreign inventors are rapidly learning to consider America as the most favourable field for the practical development of their ideas?

Our national apathy on this most important subject is, however, not quite universal. Messrs. Anderson, Mundella, Dalrymple, and Alex. Brown are about to bring in a Bill which, should it become law, will be a very great improvement. The duration of patents is proposed to be extended from fourteen years—the present limit—to twenty-one. The stamp duties are to be reduced to £85, of which £10 are payable on obtaining the patent, £25 at the end of seven years, and £50 at the end of fourteen years. Patents already in force may be extended to twenty-one years, and shall be exempt from the payments formerly prescribed at the end of the third and of the seventh year, if not already due, and shall be liable merely to the payments prescribed in the new scale. These proposals, if carried out, would be a boon alike to inventors and to the nation at large. There is extension of time, reduction of cost, and though the vicious system of successive duties is not wholly abandoned, yet every patent, not otherwise voidable, is safe for seven years, which will give the patentee some chance at least of getting it adopted in practice.

Unfortunately, in opposition to this wise and moderate Bill, a measure is to be brought in under the auspices of Government which

"— keeps the word of promise to our ear
And breaks it to our hope."

The duration of a patent is to be extended to twenty-one years. But this boon is to be purchased at a cost of another £100, payable at the end of the *twelfth* year for the very suspicious reason alleged in the memorandum of explanations that the "public"—i.e., pirates—"may

have long notice of the patentee's intention to renew beyond the fourteen years." We almost fear that in these words lurks a possibility that the continuance of a patent for the remaining seven years may be opposed. The stamps duties payable on obtaining the patent are, indeed, to be reduced to £12 10s., but with the further duties at the third, seventh, and twelfth year the total cost will be increased to the enormous sum of £262 10s., whilst the opportunities lapsing from non-payment will be increased from two to three. As a still further blow to security of possession we find the following most mischievous clause:—"A patent shall be liable at any time after the end of three years from its date to be revoked on either of the following grounds:—(a) That the patentee fails to use or put in practice the invention to a reasonable extent within the United Kingdom, or to make reasonable efforts to secure the use or practice thereof there, proof to the contrary whereof shall lie on him; or (b) that he fails to grant licences to proper persons requesting the same, on terms which the Lord Chancellor deems reasonable."

When we remind our readers that in the general opinion of practical men it is decidedly exceptional for a patent to be brought into operation so early as the third year, except the inventor happens to be a capitalist, they will agree with us that this clause, if not in intention a cunningly-devised proviso for the confiscation of patent right, will act as such in practice. Men who would otherwise have come to terms with the patentee will, if this clause becomes law, wait till the third year has expired. We admit that a patentee who works his invention in some foreign country and refuses to do so in the United Kingdom might justly be held to have forfeited his rights. But this end could surely be attained without in substance enacting that no poor man shall hold a patent for more than three years.

To give the introducers their due, the Bill contains a few good features. The time of provisional protection before giving notice to proceed is extended to nine months, and if a stamp duty has not been paid at the proper date from accident or mistake the Lord Chancellor may, on petition, enlarge the time so as not to exceed three months longer. We know instances where patentees for want of this arrangement have been compelled to apply for a Private Act of Parliament—a most costly remedy. There are also increased facilities for amendment, disclaimer, &c., even after sealing.

Still, notwithstanding these minor improvements, if we consider that the cost of a patent, instead of being greatly reduced, will be augmented, and its character of permanence within the allotted term as greatly decreased, we can only pronounce this measure a step in the wrong direction, which it is the duty of all friends of the industrial progress of the nation to oppose by every means in their power.

ON VAPOUR-DENSITIES.

By JAMES T. BROWN.

Now that V. Meyer and C. Meyer have perfected a vapour-density method, which is not only extremely simple but is performed so rapidly that it will render previous methods matters of history, it seems to me that the only thing to prevent beginners from shirking the subject, as they certainly do, is to simplify the formulæ. The vapour-density must be—

wt. of substance

— wt. of air displaced by vapour

and when expressed in that form it is easily intelligible, but although different chemists find it convenient to arrange their formulæ in various ways, still when they publish their methods they should express them in the typical form. If (taking the weight of a c.c. of air at 0.0012932) instead of using Meyer's constant 587780 we

employ its reciprocal, we have the factor 0'00000170157, and then the formula becomes—

$$\frac{S}{(B-w)V \frac{0'00000170157}{1+0'00367t}}$$

As this factor is the weight of a c.c. of air at 0° C. and 1 m.m. pressure, it is the basis of the tables that I calculated. The very brief remarks that I made at the Chemical Society referred solely to the formulæ of the methods based on the *overflow* of mercury, and were an introduction to the hope that I expressed that someone would thoroughly investigate the very interesting subject of vapour-tensions at high temperatures.

ON MANGANESE STEEL.

By SERGIUS KERN, M.E., St. Petersburg.

THE author had an opportunity of analysing some steel shavings from a broken pinion-wheel. It was stated that the pinion was in use for only a month, in the coupling of a rolling-mill for rails, when the pinion suddenly cracked in two halves; some of the pinion teeth were also damaged. The fracture had a very fine grain. Analysis gave the following results:—

	Middle Part. Per cent.	Broken Teeth. Per cent.
Sulphur.. .. .	0'10	0'09
Phosphorus	0'27	0'27
Copper	0'01	trace
Manganese	1'50	1'51
Carbon	0'65	0'65

These results prove the metal to be the so-called manganese steel. Certain metallurgists tell us that such a metal resists shocks very well, and that this enormous quantity of manganese added to the metal neutralises the evil effects of phosphorus. But the best thing that can be done is to avoid the use of such cast-metal cured by manganese. Two strips of the same metal when white-hot were welded together, but when it was attempted to bend them the first blow divided the strip into two pieces through the weld. Steel must not contain more than 0'3 to 0'4 per cent of manganese, and a metal containing 1'50 to 2'00 per cent of manganese is in most cases good for nothing. Inferior material, if even cured by manganese, will always give inferior steel. But as certain works prepare such a curious steel, it would be a benefit for the buyers if the manufacturers would supply them with a true analysis of the steel, because otherwise the buyer may get a cast-metal which only the manufacturer can call "steel."

THE MANUFACTURE OF POTASSIUM IODIDE.

By E. SCHERING.

THE following three methods are in actual use:—

- (1.) Decomposition of barium iodide (obtained from barium sulphide and iodine) with potassium sulphate.
- (2.) Introduction of iodine into caustic potassa; evaporation to dryness, and fusion with carbon in order to reduce iodate.
- (3.) Decomposition of ferroso-ferric iodide with potassium carbonate.

Satisfactory results can be obtained by any of these methods, and the choice must be determined by local considerations.

In method No. 1 the preparation of a barium sulphide

of high and regular strength is not unattended with nuisance, and the lixiviation of the barium sulphate requires much time. On the other hand, potassium sulphate can be obtained cheaper and purer than the corresponding carbonate, whilst the barium sulphate can be readily utilised for the reproduction of sulphide.

Method No. 2 obviates the necessity for washing a precipitate, and yields at once a very strong solution of potassium iodide; but the preparation of pure caustic potassa, and the concentration and subsequent fusion are circumstantial and tedious. The author therefore prefers the third method, as ferroso-ferric iodide is easily prepared and the carbonate of iron is readily washed.

To obtain cubic crystals of a porcelain-like appearance it is essential in the first method to ensure the complete decomposition of the barium sulphide by the iodine: if alkaline sulphides are mixed with the potassium iodide the crystals are paltry. If the lye contains iron sulphide, which is soluble in hot and concentrated potassium iodide, the crystals take a blue appearance. An excess of iodine dissolves foreign metals present in the barium sulphide, and the crystals may then be discoloured.

In the case of the second method, irregularity in melting may produce iodic acid, and a caustic potassa not free from sulphates causes the presence in the lye of alkaline sulphide. Both these injurious impurities must be removed prior to crystallising.

In the third method these annoyances are excluded. Salts of sodium must in all cases be avoided. Some manufacturers, to avoid the presence of sulphides, leave purposely a trace of iodate in the lye. The result is that the crystals turn yellow. The presence of lead in the iodine is exceedingly objectionable. This metal is soluble in concentrated potassium iodate, and cannot be precipitated by sulphuretted hydrogen except after great dilution.

If not removed lead affects not merely the colour but the forms of the crystals.

No demonstrable trace of potassium carbonate is admissible either for medical or photographic purposes. Potassium iodide, therefore, should be unaffected by salts of barium. The perfect absence of chlorine can never be attained, as even the best sample of iodine as well as of potassium carbonate contain traces of this impurity.

The Chilian iodine, obtained from soda-salt-petre, is becoming a formidable rival to the European product, which cannot be offered at a reduced figure as the manufacturers have lost their market for potassium chloride in consequence of the rivalry of the Staassfurt mines. Chilian iodine is met with in commerce either as a paste or as copper iodide.—*Chemische Industrie.*

CHEMICAL CALCULATIONS.

WE have received from Mr. Lupton, Professor of Chemistry at Harrow, a card destined to assist beginners in the solution of "chemical problems." By this expression the authors means, of course, not the many unsolved questions in chemical science with which so many highly disciplined minds are now grappling, but the problems which are given to pupils as means of instruction, and which, according to Mr. Lupton, "now form a large part of the chemical training at many schools." The card seems to us useful and well arranged for this purpose. It comprises a table of forty-one of the more abundant elementary bodies with their atomic weights and the corresponding logarithms. There is also a table of constants, chemical and physical, with their logarithms.

Whilst we have great pleasure in acknowledging the value of these tables, we cannot help considering it a misfortune that chemistry should be taught merely from books and calculations. We do not deny that the student may thus acquire an extensive and a fairly accurate knowledge of chemical facts and of chemical laws. But the

main educational value of chemistry, and, in like manner, of physics and biology, as it seems to us, lies herein—that these sciences, practically taught, train the mind and the outward senses to deal with objects, natural or artificial, and to draw conclusions from facts observed. They thus supply a grievous want in the ordinary system of English public school education where the intellect has been, till lately, solely engaged with words and with abstractions.

ON INDIGO-BLUE
FROM
POLYGONUM TINCTORIUM AND OTHER
PLANTS.

By EDWARD SCHUNCK, Ph.D., F.R.S.

SOME papers read before the Society many years ago, and subsequently published in its "Memoirs,"* contain an account of my experiments with the leaves of the *Isatis tinctoria*, or common woad, the well-known plant employed in Europe for dyeing blue before the introduction of indigo from the East. I showed that the leaves of this plant do not, as some have supposed, contain either indigo-blue or its hydride ready formed, but yield by careful treatment a peculiar glucoside—indican—which, when acted on by acids and other reagents, splits up into indigo-blue and indigo-glucine, the latter being a body resembling glucose. My experiments also show that this substance, indican, is a highly unstable body, undergoing when its watery solution is heated for some time, or, more rapidly, by the action of caustic alkalies, an entire change, on the completion of which it no longer yields indigo-blue by decomposition with acids, but in place of the latter gives indigo-red, indifulvine, leucine, and other products. Though I succeeded in ascertaining the composition of indican and the relation in which it stands to indigo-blue, the difficulty of obtaining large quantities of it in consequence of its excessive liability to change, prevented my proceeding further with the investigation. It seemed to me, however, that it might be of some interest to ascertain whether other indigo-yielding plants contain ready-formed indigo-blue (as has been maintained with so much persistence), or whether the colouring-matter exists in the vegetable cells in the form of indican or some other glucoside; and I have accordingly examined such of the plants known to give indigo as I have been able to procure.

Before stating the results to which I wish to direct attention on this occasion, I may mention an observation belonging, strictly speaking, to the part of the subject previously treated of, which, however, I will now describe in a few words, as I may not have another opportunity of doing so. In my last memoir I stated that, among the products of decomposition of indican from *Isatis tinctoria*, leucine is usually found, sometimes, indeed, in considerable quantities. In some more recent experiments made with woad leaves I obtained, besides leucine, a substance having all the properties of tyrosine. This substance was only slightly soluble in cold water, but soluble in boiling water, from which it separated on cooling in long needles, forming, when dry, a snow-white felted mass. Its watery solution gave the well-known reaction with mercuric nitrate. Its solution in concentrated sulphuric acid, after neutralisation with barium carbonate, gave a purple colour with ferric chloride. According to Prof. Gamgee, who had the kindness to examine the substance for me, it showed under the microscope the forms characteristic of ordinary tyrosine. There could be no doubt therefore, of its identity with the latter. As the tyrosine in this case was not obtained from pure indican, but from the crude alcoholic extract of the leaves, it is impossible to say whether it pre-existed in the plant or whether it was a pro-

duct of decomposition of the indican of the extract. The latter supposition is the most probable one; for tyrosine being almost insoluble in alcohol could hardly be contained in any appreciable quantity in the alcoholic extract of the leaves.

Some connection between tyrosine and indigo-blue has frequently been suspected by chemists. Indeed a glance at the formulæ of the two bodies will show that some connection is possible, since, by replacing H by CH₃ in indigo-blue and adding 2H₂O, we arrived at the formula of tyrosine, thus:—

In order to explain the formation of tyrosine from indican we may suppose the latter to split up into tyrosine, indigluceine, acetic acid, and carbonate dioxide, thus:—

Supposing the tyrosine in this case to have been really formed from indican, the question suggests itself whether the leucine and tyrosine so frequently found in the animal organism as products of disease, may not be derived from some substance similar to indican rather than directly and immediately from albuminoids.

Polygonum tinctorium.

This plant has long been known and employed as a source of indigo by the Chinese. According to Stanislas Julien*, who has given translations from Chinese works of various process for extracting indigo from the leaves, the plant is called in China Lán, the most productive variety being termed Tcha-Lán, i.e. the Lán resembling the tea shrub. It was introduced into Europe in the eighteenth century, and at one time, particularly about the years 1838 to 1840, formed the subject of numerous investigations by eminent French botanists and chemists, such as Turpin, Joly, Baudrimont, Pelletier, Robiquet, and others, some hopes being entertained that the plant might be cultivated profitably in France. The numerous trials made with this view having led to no result, the matter fell again into oblivion, and this interesting plant remained what it was before, a mere curiosity.

I obtained the seeds of the plants from Messrs. Vilmorin, Andrieux, and Co., the eminent horticulturists of Paris, and therefore felt sure of their genuineness. They were sown in a hotbed, and germinated rapidly. As soon as the young plants were a few inches high they were transplanted into the open ground, where they grew vigorously, producing an abundance of leaves and attaining during the summer season a height of nearly three feet. Towards the end of summer spikes of pretty pink flowers, resembling those of other species of *Polygonum*, made their appearance. The seed, however, did not ripen in the open air, the plant being cut down by the early frosts before this could take place; but, by growing a few plants under glass, I obtained a quantity of well-matured seeds, which yielded another crop in the following season.

For a botanical description of *Polygonum tinctorium* I must refer to Turpin† and Joly,‡ the latter of whom has given a full account of its structure and affinities. Of the various organs, the leaves, being the seat of the blue colouring-matter, are alone of any interest to the chemist. These leaves, which are large, oval in shape, and glossy, show no indication of the presence within their tissue of any pigment besides the chlorophyll to which they owe their lively green colour, except, occasionally, in certain places where they have suffered injury from the bites of

* *Comptes Rendus*, t. vii., p. 703.

insects or from others causes, and where blue spots make their appearance—a phenomenon which I shall endeavour to explain presently. It is nevertheless easy to show that they contain a considerable quantity of what the French call a *matière colorable*, i.e., a substance which, though colourless in itself, yields colouring-matter by appropriate treatment. A few leaves having been cut into pieces and rubbed up with a little water in a mortar to a thin paste, the mass is poured on a bit of calico, and yields, by squeezing and kneading, a green muddy liquid which, on the addition of a little sugar of lead solution, gives a green flocculent precipitate containing the chlorophyll, albumen, and other matters previously held in suspension. The liquid filtered from this precipitate is clear and yellow, and on being mixed with sulphuric or hydrochloric acid and left to stand for several hours, yields a deposit consisting of tolerably pure indigo-blue. The amount of colouring-matter obtained in this way from *Polygonum tinctorium* is far greater than that which the same quantity of wood-leaves grown in the same locality would produce, proving that the yield is influenced not only by soil and climate, but also by the peculiar nature of the plant.

The isolation of the *matière colorable* of *Polygonum tinctorium* is still not a very easy task. The same precautions must be observed as in the case of *Isatis tinctoria*, particularly as regards the evaporation of the solvents employed, which must always be effected without applying artificial heat. Unless some means are at disposal for evaporating rapidly at the ordinary temperature, by means of a current of air or otherwise, success is very uncertain. The method formerly employed in preparing indican from *Isatis tinctoria* was first tried. The leaves of the plant were dried in a stove moderately heated, and, while still warm, ground to powder. The powder, which had the colour of fresh hay, was passed through a hair sieve to separate the leaf-stalks and other fibrous portions, and then extracted in a percolator with spirit of wine. The green alcoholic extract was evaporated in a shallow tin dish, the evaporation being assisted by passing a current of air over the surface of the liquid in the apparatus formerly described. Chlorophyll and fatty matter were deposited during evaporation, leaving a brown watery liquid, which was poured off, agitated with freshly precipitated copper oxide, and filtered. The copper in the filtrate was precipitated with sulphuretted hydrogen, and the filtered liquid was evaporated as before. The residue was treated with absolute ether, which dissolved a portion, and left, on evaporation, a yellow syrup. This syrup is the indigo-producing body as pure as it is possible to obtain it. I prefer to this the following process, as being more expeditious and surer. The alcoholic extract of the dried leaves having been evaporated, the watery liquid which is left is mixed with acetate of lead solution, which gives a dirty yellow precipitate, consisting of chlorophyll and other impurities in combination with lead. To the clear yellow filtrate basic lead acetate is added; this gives a primrose-yellow precipitate, which is filtered off and, after being washed with water and then with alcohol, is suspended in absolute alcohol, through which a current of carbonic anhydride is passed. After the gas has passed through for some time the liquid acquires a yellow colour, and, after being filtered from the insoluble portion, consisting principally of lead carbonate, is evaporated at the ordinary temperature. Water added to the residue leaves a portion undissolved, which is filtered off. Sulphuretted hydrogen is passed through the filtrate to precipitate the lead contained in it; and having been again filtered, it is evaporated, when it leaves a syrupy residue which may be treated with ether as before.

The indigo-producing body thus obtained is, if it be permitted to draw a certain conclusion from mere qualitative reactions, identical with the indican of *Isatis tinctoria*. Its appearance is that of a yellow transparent syrup, showing no tendency to assume a crystalline form. It is soluble in water, alcohol, and ether. The watery solution has a more or less acid reaction. It becomes of a deep yellow

colour on the addition of caustic alkali, and gives with basic lead acetate a light yellow precipitate. When the watery solution is mixed with a little sulphuric or hydrochloric acid and left to stand for some time, the surface of the liquid becomes covered with a film of indigo-blue, a deposit of the same substance being usually formed at the bottom. The filtered liquid shows, when tested with a salt of copper and an excess of caustic alkali, the well-known reaction of glucose. If, however, the watery solution is left to stand at the ordinary temperature for a considerable time, or if it is simply boiled for some time, or if it is mixed with caustic alkali and left for a short time, it no longer yields indigo-blue on the addition of acid. This is probably due, as I have shown to be the case with indican, to a molecular change, resulting, when completed, in the formation of a body which, when decomposed with acids, yields indirubine and brown resinous substances in place of indigo-blue. When a large quantity of watery solution is mixed with acid and left to stand, a portion of the substances undergoes, it seems, the same change; for the deposit formed when operating with one litre or more of the solution contains not only indigo-blue, but also indirubine, indifulvine, and other products. The deposit, which in this case is almost black, after being filtered off, washed, and dried, is treated first with caustic alkali and then with cold alcohol, in order to remove the indifulvine and other resinous substances. On treating the residue with boiling alcohol, the indirubine dissolves, and is obtained, after several crystallisations, in the beautiful dark-red needles characteristic of the substance. The portion insoluble in boiling alcohol is indigo-blue, requiring for its purification merely to be dissolved in some suitable menstruum, such as boiling aniline. I am inclined to think that the same molecular change takes place in the cells of the plant during the later stages of its development; for I obtained from some leaves gathered late in the season when the flowers had begun to appear, a quantity of indican having the usual appearance, but giving, by decomposition with acid, far less indigo-blue and more indirubine and other products than the indican from younger leaves. This result was confirmed by experiments, to be described presently, made with the leaves themselves.

(To be continued.)

NOTICES OF BOOKS.

A Practical Treatise on the Manufacture of Sulphuric Acid. By A. G. Lock and C. G. Lock. London: Sampson Low, Marston, Searle, and Rivington.

We have here a thoroughgoing and a practical book on what may fairly be pronounced the most important branch of industrial chemistry. The authors, unlike too many compilers of so-called technological works, do not content themselves with generalities, but enter closely into working details. The construction of the kilns and chambers, with their accessory arrangements, the selection of materials, the points needful for economy in management, and the prevention of waste and nuisance, are all carefully and clearly presented to the reader, with the important aid of seventy-seven "construction plates" drawn to scale and showing the chief recent improvements.

It may seem strange, if not somewhat humiliating, that in a manufacture so old and so widespread as that of sulphuric acid, and depending so little on manipulative niceties, there should be so much divergence of opinion concerning arrangements of plant and methods of working. Still, from another point of view, it may be held consolatory to know that one, and that not the smallest, of our national industries is capable of very decided improvements if those who combine the opportunity and the requisite knowledge will give the question the careful examination it deserves.

Our authors begin with a consideration of the raw

material, a subject which derives additional importance from the growing objection to the industrial uses of arsenical products, and from arsenic no pyrites are absolutely free. It remains to be seen whether the vast deposits of sulphur in Iceland may not enable us to overcome this difficulty, situate as they are so much nearer our shores than are the Sicilian mines. We notice that Messrs. Lock quote from Mr. H. A. Smith the statement that in certain Irish pyrites the arsenic present exceeds 2 per cent. They are also, on an average, low in sulphur, and are very hard, if not altogether impossible, to burn reasonably clean—a fact which goes far to vitiate the details of production-cost quoted from Messrs. Richardson and Watts as to the relative economy of brimstone, of Belgian, and of Irish pyrites. In a subsequent part of the work the authors express a preference for the best-class Norwegian pyrites beyond all others.

The observations on the analysis of sulphur ores are too brief to be of much practical value, and might have been advantageously omitted, especially as this subject is discussed at length in other works.

The structure of kilns for brimstone and for different qualities of pyrites is treated very fully, with the aid of plates representing the special arrangements for a rich Norwegian ore, for a poor Irish, and for the poor English sulphur ores from the coal-fields, commonly known as "coal-brasses" or brass lumps. There are, besides, representations of the kiln fronts of Messrs. Daglish and Co., and of Gerstenhofer's kiln, now very extensively, and we believe successfully, used on the Continent.

The capacity, shape, and arrangement of chambers are considered in the second chapter. Here, it must be owned, practical men are very far from having come to a unanimous conclusion as to the best construction—an evident proof that we have here much still to learn. The authors quote with disapprobation, or at least with strong doubt, the dimensions recommended by Mr. H. A. Smith, viz.—"Length, 160, 200, or even 210 feet; width, 30 feet, increasing in ratio to length; and height, 10 feet, not to be increased for any length of chamber." As grounds for rejecting these proportions they allege the great consumption of lead in proportion to bulk, and they show that a chamber 210 feet by 30 feet, having only 1 inch of acid all over the bottom—the very smallest depth needful to prevent the escape of the gases—will lock up 23 tons of acid. As the opposite extreme they mention Hasenclever's proportions, where the minimum height of the chambers is fixed at 32½ feet to 130 feet in length and 32½ feet in breadth. It surely ought to be possible to decide which of these two glaringly opposed systems gives in practice the best results, and whether either of them is preferable to the less extreme dimensions recommended by the authors, viz.—in a set of 60 feet long, 27 wide, and 23½ feet high, and 30 feet long, 23 feet wide, and 22 feet high.

The proposal to inject "atomised" or pulverised water into the chambers in place of steam is next passed under review, as also the suggestion to admit a solution of nitre in the form of spray. But on these questions the authors, though citing the opinions of others, do not appear to have formed any decided conclusion of their own.

The evidence adduced on the proposal to use free nitric acid instead of nitrate of soda seems decidedly favourable to this system, which is almost universally adopted on the Continent. In some German works the consumption of nitre in this form has been brought as low as 1½, 1¼, and even, it is said, 1 per cent of the sulphur present in the pyrites. The nature of this economy will be fully appreciated if we remember that where no Gay-Lussac's or Glover's tower is in use some manufacturers use 9 or even 10 lbs. of nitre to every 100 lbs. of sulphur actually burnt, and that even where such contrivances are at work the proportion often reaches 5 per cent. Dr. Lunge, whom we consider an excellent authority, considers the free acid so much superior to the nitre that nothing but a fear of having too much difficulty with the workmen in the first instance would deter him from discarding the latter system in England.

This last remark suggests some unpleasant reflections. One of the many reasons which place us at a disadvantage in competing with foreigners is the obstinacy with which the British workman clings to traditional methods, and his disinclination to give fair play to any new invention which he may be called upon to adopt.

The chapter on "chamber construction" is admirably complete and practical.

In treating of "condensers and columns" the evidence for and against the use of the Glover tower is fairly stated. The authors consider it certain that in large works, at least, this tower will become as common an adjunct as the Gay-Lussac column.

The succeeding chapters on the concentration of the acid, on the utilisation of waste products, and on accessories must be pronounced satisfactory, though we regret that want of space forbids us to examine them in detail. The final sections on attempts to manufacture sulphuric acid without the use of chambers, and on the so-called Nordhausen or fuming acid, will also be found valuable and suggestive. The latter acid is now in extensive demand in the arts, e.g., in preparing the sulpho-conjugated acids of certain coal-tar colours, and in the purification of ozokerite. As shippers and railway companies dislike undertaking its conveyance there is the greater need for its production on the spot.

In concluding this necessarily brief sketch, we beg to record our opinion that though no reading will enable a man to dispense with actual experience, yet that the authors have done all that can be done in the form of a book. Every chemical manufacturer, every scientific chemist who is at all connected with practical operations, has room for gratitude to the authors.

The book is admirably got up, and reflects great credit on the publishers.

Our Domestic Poisons, or the Poisonous Effects of Certain Dyes and Colours Used in Domestic Fabrics. By H. CARR, M.Inst.C.E. London: Ridgway.

ARSENIC is in more senses than one a delicate thing to handle. On a somewhat similar occasion we ventured to put to the accuser a few questions, such as would have been urged by counsel if the matter had come before a court of law, and in consequence we were half buried beneath a heap of indignant letters. In the present pamphlet it is maintained that "national health is suffering from the use of arsenic and other poisons in the manufacture of domestic fabrics," and the author takes in hand to arouse public feeling with the end of demanding legislative interference. For this purpose he has put himself in communication with certain eminent physicians and chemists, and has obtained from them evidence more or less confirmatory. The first point which here strikes us is that Mr. Carr has not—as far as here appears—applied to any chemist specially and practically acquainted with the arts of dyeing and calico-printing and able to inform him what poisonous colours are actually in use and what are the circumstances of their application. The instances of poisoning given, at least, as far as textile fabrics are concerned, are by no means as explicit as could be wished. We seek to know in such cases the name and address of patient, medical adviser, and chemist, if one has been called in; the date of the occurrence, and the precise name of the colour said to have occasioned the mischief. The terms "mauve-dyed articles," "beautiful red, scarlet, and mauve colours," &c., are too vague to be employed in so serious a question. These demands may perhaps seem stringent, but it would be difficult to name any subject which has given rise to so many newspaper canards as the alleged poisonous character of dyes. Our contemporary, Dr. Reimann, of the *Färber Zeitung*, has been at the pains of sifting not a few of these stories. In many cases it was found on rigid scrutiny that the alleged sufferer and his doctor were both non-existent. At other times the source of the disease has been declared to be

some dye which is not in the market at all, or which, if known, could not by any means produce the colour in question. The celebrated shoe-maker of Stettin, whose inflamed eyes were first ascribed to an arsenical hat-lining, but were afterwards traced to a diligent internal use of potato-whiskey is a case in point. We have no objection to Mr. Carr collecting instances of poisoning from dyes, but they should be such as will bear cross-examination. As far as arsenic is concerned we must bear in mind that there are many channels other than dyes and pigments through which it may be introduced into the human system. If we remember the violet powder case we may well suspect that arsenic is one ingredient of the cosmetic powders which so many ladies apply to their hands and faces.

As regards the aniline colours their physiological action is still a matter of doubt. That aniline itself is poisonous is far from being a proof against its derivatives. Much research will therefore be needed before either physicians or chemists can form a decided opinion on the safety of any given dye or pigment, and such research, thanks to the Vivisection Act, has been rendered in England all but impossible. Meantime we should do nothing rashly. If we burden our colour makers, dyers, and printers with regulations from which their competitors in France, Germany, &c., are free, we shall merely strike a heavy blow at our national industry. In none of those countries is there any restriction on the use of non-arsenical coal-tar colours in textile manufactures.

The British Journal Photographic Almanac and Photographer's Daily Companion for 1879. Edited by J. TRAILL TAYLOR. Henry Greenwood.

THE twenty-fifth issue of this well-known year-book gives a vivid idea of the immense progress which photography has made in this country since first it put forth its few modest leaves. Besides the usual information contained in almanacs we have 200 pages containing succinct accounts of every photographic process and discovery belonging to the past year, condensed from an immense number of scientific *Transactions* and journals from all parts of the world, prefaced by a summary of the progress made in photography during the past year. Mr. Taylor secedes from the editorship of the Almanac this year. May we suggest to his successor the advisability of classifying the information given in the body of the work under distinct headings instead of allowing it to be mixed up in picturesque disorder as at present. There is a copious index appended to the book. As an instance of the enterprise of photographic material dealers we may mention that the almanac contains nearly one hundred and fifty octavo pages of advertisements.

The Patentees' Manual: being a Treatise on the Law and Practice of Letters Patent, especially intended for the Use of Patentees and Inventors. By JAMES JOHNSON, Barrister-at-Law, and J. HENRY JOHNSON, A.I.C.E., Solicitor. Fourth Edition. Longmans and Co. 1879.

This is the fourth edition of Messrs. Johnson's standard work, and is a great advance on the preceding ones. The whole text has been thoroughly revised, and several of the chapters greatly enlarged or re-written. A new chapter on Oppositions to the Grant of Patents has been added, and the latest decisions of the Courts incorporated with the text. The new German and Spanish Patent Laws have been given, and the Appendix contains an account of those of our Colonies, as well as a reprint of all the Acts of Parliament bearing on the subject, with references to typical cases decided thereon. Messrs. Johnson may be congratulated on the successful way in which they have respectively completed their arduous task. Their work is another instance of the truth of Adam Smith's grand theory of the division of labour. There is a copious index at the end.

CORRESPONDENCE.

TENACITY OF STARCH.

To the Editor of the Chemical News.

SIR,—I have read with interest the method employed by Mr. George Whewell for determining the tenacity of starch, but think it right to call attention to the last paragraph of his paper, which gives the conclusions he draws from his experiments; these in my opinion are entirely erroneous. He says in effect, If the paste given by one sample of starch is firmer or has more "tenacity" than that given by another, the former will give more stiffness to the cloth into which it is introduced in direct proportion to the resistance which it offers to a weight placed on its surface. If this be so, then supposing we take calcined farina (British gum), and dissolve it by boiling in the smallest proportion of water possible; it would make a syrup which would not support any weight placed on its surface, and consequently, according to Mr. Whewell's theory, would not give any stiffness to cloth when used in sizing. And yet it is undoubtedly the case that if we make solutions by boiling equal weights of British gum and farina with equal weights of water, and pass threads or cloth through each, and then dry them, the former solution will give more stiffness to the threads or cloth than the latter, and weight for weight the farina which possesses the *least* "tenacity" would produce the greatest stiffness, because the thinner the sample boils the more easily will the solid matter be able to enter the fibre, and it will enter in greater quantity. I know that the opinion expressed by Mr. Whewell is held by many manufacturers, but it is fallacious.—I am, &c.,

WILLIAM THOMSON.

Royal Institution, Manchester.

CHLORIDE OF CALCIUM.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxix. p. 97, Mr. O. Gluge, of Sarrebrück, in a "Note upon Chloride of Calcium," refers to its manufacture as a by-product in the manufacture of alkali by the Solvay process; but he does not seem to be aware that it is also a by-product in the manufacture of bicarbonate of soda by the Leblanc process and of bleaching-powder by the Weldon process. We have made chloride of calcium for sale by one or both of these processes for upwards of fifteen years, during a considerable portion of which time our sales have exceeded thirty tons weekly. If Mr. Gluge will refer to the back numbers of the CHEMICAL NEWS he will find that for many years our product was advertised in your pages.—We are, &c.,

GASKELL, DEACON, AND CO.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—The letter of Mr. Charles E. Groves, written in answer to mine signed "A Disgusted Promoter," commences by accusing me of inaccuracy, the only instance adduced being that I referred to the recent conference as one on the "Adulteration of Food and Drugs" instead of the "Adulteration of Articles of Food." It is true that Mr. Groves also points out that when my letter appeared the conference which I spoke of as pending had already taken place, but you, Sir, if my original MS. is still extant, will know that my letter was *written and received* by you a few days *before* the date fixed for the second conference. There is another error in my letter which I will give Mr. Groves the benefit of. I spoke of the conference on trade

certificates being held in December, whereas the true date of the meeting was November 22.

Although it was true when I wrote my last letter that no report of the November conference had been published, the statement is no longer correct, for *since my letter appeared in your pages* the members have received a printed report of the proceedings. Will Mr. Groves excuse the suggestion that its circulation is a *consequence* of my criticisms? Whatever may be the cause, it is satisfactory to find that the Council have published the report, though it has taken them *nearly four months* to do it.

I may remind your readers that I did *not*, as stated by Mr. Groves, "recommend Fellows not to pay their subscriptions," but merely suggested that they should defer doing so until the Council proposed to spend the large sum of money already in hand. Mr. Groves will best serve the Institute by publishing a candid statement of the plans of the Council. To gain this was the object of my last letter, but Mr. Groves wholly ignores my challenge, in his reply, though from the fact that the Report of the Council has just been circulated amongst the Members I conclude that he is alive to the nature of it.

My letter having secured the chief results aimed at, I beg to subscribe myself

AN APPEASED PROMOTER.

March 15, 1879.

VICTOR MEYER'S NEW METHOD OF VAPOUR DENSITY DETERMINATION.

To the Editor of the Chemical News.

SIR,—Referring to the interesting note by Greville Williams, F.R.S., in the CHEMICAL NEWS (vol. xxxix., p. 110), I see he mentions having abolished the funnel, *d*, figuring in the woodcut (page 66). Now this funnel-like aperture is somewhat exaggerated in the printing, and in reality the opening or widening is very little larger than the main stem of the instrument, and just conveniently sufficient to admit a small india-rubber stopper, which V. Meyer always uses. The advantage of the transparent glass vessel or bath, *c*, is that the ascent of the heated vapours can easily be seen on boiling the liquid—the bulb—and so the operation is more conveniently regulated. I may also mention that Prof. Victor Meyer has not only had the instrument made of porcelain (better for several reasons than metal), but has made and is making by means of this instrument (identical in every other respect with the glass one) a number of interesting determinations of the vapour-densities of certain extremely high boiling inorganic substances, leading to still more interesting theoretical conclusions.—I am, &c.,

WATSON SMITH, F.C.S., F.I.C.

Zürich, March 17, 1879.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 8, February 24, 1879.

Induced Currents Resulting from the Movements of a Coil across an Electro-Magnetic System.—M. Th. du Moncel.—The induction currents in action in the Gramme machine consist of those which result from the movement of the covered spirals before the inducer and of those determined by the inversions of the polarity of the iron ring.

Observations with Reference to M. G. Planté's Recent Work "Researches on Electricity."—E. Becquerel.—A secondary battery of 800 elements arranged

on M. Planté's system, which may be easily charged by means of two nitric acid elements, can give effects of tension equal to those of 1200 nitric acid elements. These currents are of course temporary, and the apparatus serves a kind of condenser of voltaic currents, but they are sufficiently permanent to produce mechanical, thermic, and luminous effects of great power.

Hemihedral Forms of Alums.—Lecoq de Boisbaudran.—The author presented to the Academy a crystal of alum having four smooth and four rugged surfaces, arranged so as to represent the union of two inverse tetrahedra. It was obtained by steeping an octahedron of chromo-potassic alum for some hours in a slightly super-saturated solution of basic ammonia-alum.

Resistance to a Change of Condition of Crystalline Surfaces in Presence of their Mother-liquor.—Lecoq de Boisbaudran.—The action of different isomorphous crystals upon the solution of any one of them is not the same. The transition from the state of the very slow dissolution of a crystalline surface to its very slow increase is not effected abruptly in consequence of an extremely slight change in the concentration of the liquid, but each surface remains intact without either gaining or losing substance in a mother-liquor, the strength of which ranges within certain limits, which, though narrow, are easily perceived. The resistance to a change of state is modified for each system of surfaces independently, in such a manner that an alteration in external conditions (a change in the composition or in the temperature of the liquid, &c.) involves generally a change in the relation of the resistances of the two given systems of surfaces. Contrary to the opinion of some authorities, there does not exist a state of mobile equilibrium between a crystalline surface and its mother-liquor; there is no continual interchange of molecules, but merely a continual erosion or a continual deposition, and within the limits of resistance to change of condition there is neither erosion nor deposition.

Reflections on the Communication made by M. de Lesseps Concerning the Contagion of the Plague.—M. Bouillaud.—The author considers that the researches of M. Pasteur on the low organisms considered as propagators of disease must greatly modify our views on the spread of epidemics.

Projection of Molecular Shadows.—W. Crookes.

Action of Various Coloured Light upon a Layer of Silver Bromide Saturated with Various Organic Colouring Matters.—Ch. Cros.—Upon plates sensitised with an extract of mallows the direct spectrum of the Drummond light is inactive in the medium green, but very active at the red and the violet extremities. With carthamin the mean portion is most active, and with chlorophyll the action extends throughout the visible spectrum, and even somewhat beyond. It presents several distinct maxima and minima.

The Production of Crystalline Barium Chromate.

—L. Bourgeois.—The author heats to bright redness for half an hour 2 equivs. barium chloride with 1 equiv. potassium chromate and 1 equiv. sodium chromate; lets the mass cool slowly, when crystals of a pistachio-green are found in its interior. They are freed from the alkaline chlorides by washing with boiling water. The specific gravity is 4.60. They dissolve readily in dilute hydrochloric or nitric acid, giving an orange liquid. They are decomposed by sulphuric acid with formation of barium sulphate and chromic acid. They consist of 60.4 per cent of baryta, and 39.6 of chromic acid, corresponding to the formula BaO, CrO₃. The green colour is not due to the presence of chromic oxide.

Composition of Beer-yeast.—P. Schützenberger and A. Destrem.—The authors consider yeast as containing complex compounds, at once hydrocarbonic and proteic, formed like glucosides, and easily decomposed by acids and alkalis. The exterior of the granules differs from

the interior merely by containing more hydrocarbonic matter.

Pyrogenous Carbides of American Petroleum.—L. Prunier.—The author has discovered a compound of the composition $(C_{12}H_2)_n$, and containing 97.29 of carbon. These figures indicate the existence of a new group of incomplete carbides higher than any previously known, since benzerythren, parachrysen, fluoranthren, and pyren do not contain more than 95 per cent of carbon.

On Glycide.—M. Hanriot.—Glycide represents the alcohol corresponding to epichlorhydrin.

Production of Aniline-black by Means of the Chromates in Presence of Chlorates.—S. Grawitz.—The author denies the accuracy of the conclusions of M. Witz on the inutility of chromates.

*Verhandlungen des Vereins zur Beforderung des
Gewerbfleisses.* Heft 10, December, 1878.

This number is chiefly taken up with a paper on the theory of "Closed Air Machines." There are official communications concerning boiler explosions and the storing of petroleum.

La Correspondance Scientifique.

No. 36, February 18, 1879.

Three veins of coal have been discovered in the immediate neighbourhood of Lake Nyanza. One of them is 7 feet in thickness, and the others respectively 3 feet and 1 foot.

According to *Le Petit Marseillais* the waters of the Dead Sea are about to be worked for potash, iodine, and bromine. The projectors calculate on delivering potassium chloride in London at 90 francs per ton, thus underselling the Stassfurt manufacturers.

Chemiker Zeitung.

No. 1, 1879.

Preparation of Zinc from Blende.—The blende is partly roasted and is then treated in a muffle with burnt lime and coke. Calcium sulphide is formed and the greater part of the zinc present in the ore is volatilised. This is condensed or collected as zinc oxide as in the ordinary zinc furnaces. From the calcium sulphide sulphuretted hydrogen is evolved, and by its action upon the sulphurous acid gas given off on roasting the blende sulphur is obtained.

Process for Obtaining Tanning Agents along with Cellulose, Gum, and Acetic Acid from Vegetable Matter.—Dr. A. Mitscherlich.—Wood or other vegetable matter is treated at an elevated temperature with bisulphite of lime (under pressure?). The cellulose which is cemented together by other compounds is set at liberty in the same state in which it exists in plants. It is readily freed by washing from the accompanying substances, and can be at once utilised for paper-making, &c. The soluble substances vary according to the material employed, and embrace compounds suitable for tanning and for the manufactures of gum, acetic acid, and alcohol. The methods for separating these substances are omitted.

Dr. H. Buff, Professor of Physics at the University of Giessen, died on December 24, 1878.

Sawyer and Man's electric lamp has been tried in New York with great success. The light is produced in an atmosphere of nitrogen so that there can be no combustion and no generation of nitrogen oxides—an objection lately raised against the electric light. The cost for equal illumination is said to be only one-fortieth that of gas, and the light can be regulated from a faint gleam up to the intensity of 30 gas-jets.

Analysis of Butter.—E. Mylius finds that butter globules if examined with the microscope by polarised

light can readily be distinguished from other melted fats, as the latter display a crystalline structure.

Quality of Milk.—According to the researches of Berguerel, Vernois, and Müller the respective proportions of the constituents of milk are affected not by race but by age, diet, and other causes not yet ascertained.

No. 2, January 9, 1879.

Quantitative Spectrum Analysis.—Wolff proposes the following methods for the determination of cobalt, copper, and metallic iron. 1. Determination of very small quantities of cobalt.—A solution of cobalt-sulphocyanide, obtained by mixing a very dilute alcoholic solution of chloride of cobalt or cobaltous nitrate with an excess of alcoholic ammonium sulphocyanide, displays in the region $C_{39}D-C_{55}D$ a very characteristic absorption spectrum. By means of a solution of cobalt sulphocyanide of known strength he determines the residual strength of light in a stratum of 1 centimetre in thickness, the coefficient of extinction and consequently the absorptive proportion for cobalt. The latter number is multiplied by the volume and the coefficient of extinction of the solution under examination, and gives the weight of the cobalt present. It must be remarked that in these experiments alcohol of the exact specific gravity 0.833 must be used, because an alcoholic solution of cobalt sulphocyanide differs in the intensity of its blue colour according to the strength of the alcohol. This behaviour has been utilised by Morrel for a colorimetric determination of alcohol. 2. Determination of Copper.—The absorptive proportion for copper sulphate or for metallic copper is measured as ammonio-sulphate of copper. To determine small quantities of copper in articles of food, &c., the ash is dissolved in an acid, the dissolved copper is separated electrolytically, re-dissolved in nitric acid, and saturated with ammonia to a certain volume. The latter multiplied by the coefficient of extinction of the solution obtained and with the absorptive proportion of metallic copper as previously ascertained, shows the weight of the copper present in solution. 3. Determination of Metallic Iron.—The ferri-ferrous substance is mixed with a normal cupric solution, whose volume, coefficient of extinction, and equivalent in iron are known. The solution filtered from the deposit of copper is evaporated, oxidised, super-saturated with ammonia, separated by filtration from ferric oxide, and made up to a fixed volume. The coefficient of extinction and the equivalent in iron of this solution are ascertained; the latter subtracted from the known iron equivalent of the normal copper solution originally employed shows the metallic iron.—*Zeitschrift Anal. Chem.*, 18, 38.

Simplified Butter Test on Hehner's Principle.—Reichert saponifies a known quantity of butter, dissolves the soap in water, adds sulphuric acid, and distils. If the butter is pure 2½ grms. of the sample yield a distillate which requires at least 13 c.c. of decinormal soda.

MISCELLANEOUS.

Professor Church and the Agricultural College.—At a meeting of the Committee of Management of the Agricultural College, held last week in London, present Earl Bathurst, the Earl of Ducie, Col. Kingscote, C.B., M.P., Mr. G. Sotherton Estcourt, M.P., Mr. A. L. Goddard, M.P., Mr. T. S. Bazley, and Mr. Edward Bowly, the following resolution was passed, in reference to Prof. Church's application for permission to reside out of the College:—"The Committee of Management are of opinion that the discipline of the Agricultural College cannot be satisfactorily maintained except by the residence of professors within the College walls in conformity with the original by-law No. 47. Being fully sensible of the services rendered by Prof. Church during his 16 years' residence in the

College, they the more regret that they cannot accede to his recent proposal of non-residence, a compliance with it involving such alterations as would unduly disturb the present organisation of the College staff." We understand that, in consequence of the above decision as to Prof. Church's connection with the Agricultural College, the two resident professors next to him in seniority have resigned their respective chairs; the chair of mathematics and physics being vacated by Prof. H. W. Lloyd Tanner, M.A., that of natural history by Prof. Fream, B.Sc., F.G.S.

Science in the Streets.—Under the title of the "New Parisian Electric Pipe-lights" a number of itinerant vendors are selling in the streets of the metropolis small brass boxes containing three or four rodlets of metallic sodium, an inch long and one-tenth of an inch square. The method of using these lights, which are sold at a penny a box, is simple. A morsel of the metal is pinched off and placed on a piece of paper which has first been moistened with water or saliva. The sodium of course inflames and sets alight to the paper. The risk to person and property that will be caused by the indiscriminate distribution of such a very dangerous material as metallic sodium, which even skilled chemists are obliged to handle with the greatest care, is obvious to all who know its properties. We have on a former occasion called attention to the evil of allowing the open sale of metallic sodium in toy shops under the name of "Satan's Tears," and we believe a stop was put to it by the police. In the present instance the danger is much greater, inasmuch as any urchin who has a penny to spare has it in his power to set half a street in flames at a moment's notice.

NOTES AND QUERIES.

Gases from Vitriol Chambers.—Would any of your readers describe and explain an easy method of testing the exit gases from vitriol chambers, and state what is considered "good working." I may say we have not Gay-Lussac or Glover towers, but simply one packed with coke as a condenser.—W. L.

Substitute for Litmus.—Where can I procure small quantities of Porrier's "orange 3," "orange 4," or tropæolin OO, recently recommended as a substitute for litmus by Mr. Greville Williams?—VOLUMETRIC ANALYST.

MEETINGS FOR THE WEEK.

- MONDAY, 24th.**—Medical, 8.30.
— Society of Arts, 8. "Dwelling Houses: Their Sanitary Construction and Arrangements," by Dr. W. H. Corfield, M.A. (Cantor Lectures.)
— London Institution, 5.
— Royal Geographical, 8.30.
TUESDAY, 25th.—Civil Engineers, 8.
— Royal Institution, 3. "Animal Development," Prof. Schäfer.
— Anthropological, 8.
WEDNESDAY, 26th.—Society of Arts, 8. "The Treatment of Iron to Prevent Corrosion," Prof. Barff, M.A.
— Geological, 8.
THURSDAY, 27th.—Royal, 8.30.
— Royal Institution, 3. "Sound," Prof. Tyndall.
— Philosophical Club, 6.30.
— London Institution, 7.
— Society of Arts, 8. "The Inoxidation of Iron and the Coating of Metals and other Surfaces with Platinum, by the Processes of M. Dode," L. M. Stoffel, C.E.
FRIDAY, 28th.—Royal Institution, 9. "Geography of the Oxus, and its Changes," Sir Henry C. Rawlinson.
— Society of Arts, 8. "The Practicability and Advantage of a Ship Canal Through the Island of Rami-eran," Simon McBean, C.E.
SATURDAY, 29th.—Royal Institution, 3. "Etching," by Mr. Seymour Haden.

TO CORRESPONDENTS.

W. H. D.—We do not recollect.
C. W. W.—The best way would be to advertise it.
More Light.—Either pronunciation of the word appears to be equally correct.

The Prestolee Alkali Works, Farnworth, near Bolton, Lancashire, fitted with costly Plant, Machinery, and Apparatus for the Manufacture of Soda-ash, Bleaching-powder and Liquor, and Sulphuric Acid, in complete working order, with possession.—Preliminary.

MESSRS. FULLER, HORSEY, SONS, and CO. are instructed to SELL by AUCTION, at the Palatine Hotel, Manchester, on Thursday, April 17, at 3 o'clock precisely, in one lot, unless an acceptable offer be previously made by private contract, the PRESTOLEE ALKALI WORKS, a freehold property, having a superficial area of 95,741 square yards of land, subject to chief rents amounting to £407 13s. 9d. per annum, with the buildings, plant, machinery, and apparatus erected thereon, capable of manufacturing monthly a product exceeding in the aggregate 2000 tons of soda-ash, bleaching-powder and liquor (by Weidon's patent process), and sulphuric acid, also caustic soda and muriatic acid. The amount expended in the construction of these works has been very large. A valuation was made with great care in 1874 by Messrs. Holmes and Son, the well-known valuers, of Manchester; their estimate then amounted to £99,900, and since that time a sum exceeding £10,000 has been expended. The whole of the works and plant have been well kept, and are conveniently arranged for working. The Bury, Bolton, and Manchester Canal, which forms one boundary of the property, affords facility for economical water carriage, and the Lancashire and Yorkshire Railway is within a very short distance. There is a plentiful supply of water for all manufacturing purposes, free of cost, from the river Croal, and coals are raised from pits in the immediate neighbourhood. Pyrites, salt, lime, and limestone are all brought by boats direct to the wharf on the canal. The works may be economically worked with a small capital, as arrangements may be made with the vendors for a very considerable portion of the purchase money to remain upon mortgage. Large profits have been realised in the past, and the high reputation of the Prestolee manufactures in the market will ensure to an energetic man, even at the existing low prices, an ample return for his capital invested and possession of works not surpassed for completeness or compactness by any in the kingdom. Printed particulars are in course of preparation, and may shortly be had at the Works; at the Palatine and Queens Hotels, Manchester; of Messrs. Wakeman and Bleck, Solicitors, Warminster; and of Messrs. Fuller, Horsey, Sons, and Co., 11, Billiter Square, London, who are empowered to treat for the disposal by private contract.

Prestolee Alkali Works, Farnworth, near Manchester and Bolton.—Useful Horses, rolling stock, loose effects, and remaining stock-in-trade.

MESSRS. FULLER, HORSEY, SONS, and CO. are instructed to SELL by AUCTION, on the PREMISES, Farnworth, near Manchester, on THURSDAY, April 3, at twelve precisely, the ROLLING STOCK, loose materials, and stock-in-trade, including 16 powerful cart horses, four wrought-iron tank trolleys, nine lorries, 11 spring tip and float carts, harness, two cast-iron caustic pots, cast-iron decomposing pot, double-flue Lancashire boiler 7 ft. diameter, 19 ft. 6 long, about 30 tons useful wrought- and cast-iron material, one ton lead, brass cocks and taps, slate slabs, York stone foundations, new wire netting, useful ash timber spokes and felloes, four canal boats, earthenware aqua fortis jars and packing boxes; also 25 tons soda-ash, 72 carboys rectified oil of vitriol, 300 empty carboys and stock of bleaching liquor and powder in process of manufacture, and numerous other effects.—May be viewed the day preceding the sale, and catalogues had on the premises, of Messrs. Wakeman and Bleck, Solicitors, Warminster; and of Messrs. Fuller, Horsey, Sons, and Co., 11, Billiter Square, London, E.C., or will be forwarded on application.

BERNERS COLLEGE OF CHEMISTRY.

Instruction and preparation in CHEMISTRY and the EXPERIMENTAL SCIENCES under the direction of Professor E. V. GARDNER, F.R.S., M.S.A.

The Class Rooms are open from 11 to 5 a.m. and from 7 to 10 p.m. daily.

Special facilities for persons preparing for Government and other examinations.

Private Pupils will find every convenience.

Analyses, Assays, and Practical Investigations connected with Patents, &c., conducted.

Prospectuses and full particulars on application to Prof. Gardner at Berners College, 44, Berners-street, W.

WILLIAM AND WILLIAM T. FIELD,

MANUFACTURERS of the Celebrated STAFFORDSHIRE BLUE BRICKS, specially adapted for Chemical Plant, i.e., Acid Towers, &c. Also all other kinds of Best Staffordshire Blue Bricks, Pavings, Plyths, Splays, Copings, &c. &c. Prices and samples on Application.

TESTIMONIAL.

"We have used the Blue Staffordshire Brick for Sulphuric Acid Towers, &c., manufactured by Messrs. Field, for the last fifteen years, during which time they have given great satisfaction. We recommend them to the Chemical Trade, believing there is nothing better in the market."—(Signed) WILLIAM HUNT and SONS, Lea Brook Alkali Works, near Wednesbury, Staffordshire, February, 1876.

THE

PATENTEES' MANUAL.

A Treatise on the Law and Practice of Letters Patent, especially intended for the use of Patentees and Inventors.

BY

JAMES JOHNSON, ESQ.,

Of the Middle Temple, Barrister-at-Law, and

J. HENRY JOHNSON,

Solicitor and Patent Agent, Assoc. Inst. C.E. 47, Lincoln's Inn Fields, W.C., and Glasgow.

This Edition, much enlarged, gives a practical reference to every reported case of importance, and contains all the information on the law and practice of Patents Inventors and Patentees can require.

The Appendix contains the Statutes and Rules, and a summary of the Laws of all Foreign States and British Colonies.

London: LONGMANS and CO.

Have a Pure Body and Good Health by taking
DR. EVANS'S

PURE VEGETABLE CARBON,

NATURE'S GREAT BLOOD PURIFIER.

Perfectly tasteless, void of smell, and can be taken by the most delicate.

This new and wonderful cure for Indigestion, Wind, Foul Breath, Headache, Bile, Acidity, Incipient Consumption, Eruptions of the Skin, and all disorders that can emanate from Impure Blood.

Sold by Chemists in 2s. 6d. and 10s. cases; or post free of
JAMES GOODFELLOW and Co.,
45 and 46, CITY ROAD, LONDON.

TO BE LET, at best offer obtainable, Complete Copper Extracting Works and Complete Phosphorus Works; Acid Chambers adjoining.—Address in first instance, G. J. Blower, 38, Lowe Street, Whitmore Reans, Wolverhampton.

MAGENTA RESIDUE, and free from Lime.

An immediate purchaser may meet with a quantity cheap by Addressing Cerise, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Advertiser, who has had many years' practical experience in experimental and analytical chemistry, is desirous of an Appointment, either in England or Colonies, as Chemist or Assistant.—Address, A. B. C., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Advertiser, a German, desires an appointment in the Laboratory of a Chemical Works; he has passed the German Chemical Examinations; has had good experience in Industrial and Analytical Chemistry both in Sweden and Germany, and is now engaged with a London Firm. First-class references given.—Address, P. T., care of Schacht and Co., 6, Finsbury Place South.

Situation wanted by an Analytical Chemist acquainted with food and general analysis. Has studied in a German Laboratory and is accustomed to teaching.—Address, D, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, by an experienced man, a Situation as Manager or Sub-manager in Tar or Ammonia Distillery; thoroughly understands Sulphate of Ammonia making, and the producing, separating, and analysing of all Tar Products.—Address, 200, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO SULPHURIC ACID AND CHEMICAL MANURE MANUFACTURERS.

A Sailing Tank Barge to be Sold. Capable of carrying 50 tons of acid; fitted with steam pumps; in good condition.—May be seen at Messrs. B. Jacob and Sons' Wharf, Copperas Lane, Church Street, Deptford, from whom all particulars can be obtained.

TO MANURE MANUFACTURERS.

FOR SALE.—About 100 tons Monthly Spent Animal Charcoal on a basis of 70 Phosphate.—Address, John Schwartz, Sugar Refinery, Pelham Street, E.

YOUNG'S PARAFFIN LIGHT & MINERAL OIL CO., LIMITED.

The Directors of this Company are prepared to receive TENDERS for the supply of the GENERAL STORES required at their Addiewell, Bathgate, and Lochrin Works, and also at all their Pits, for ONE YEAR and for TWO YEARS, from 1st May, 1879, as under:—

Class No.	Class No.
1. Bolts, Nuts, and Rivets	22. India Rubber, &c.
2. Bricks, Clays, &c.	24. Lamp Founts
3. Brushes and Mops	25. Lamps—Glass
4. Candle Boxes	26. Leather
5. Canvases	27. Nails, Screws, &c.
6. Cast Iron Castings	28. Paper Shades and Holders
7. Chemical Apparatus	32. Reflectors
8. Cloths, Plaiding, &c.	29. Ropes, &c.
9. Colours	30. Shades, Moons, &c.
10. Corks	31. Shives
16. Drysalteries	39. Shovels
17. Gas and Water Fittings	33. Spelter, Tin, and Lead
18. Glass Chimneys	40. Tools
19. Grease, Soap, and Tallow	35. Wicks—Candle and Lamp
20. Gun Metal	41. Wire Ropes
21. Hardware and Sundries	

Detailed Specifications and Forms of Tender, and any other necessary information, may be obtained, on and after Monday, 24th proximo, at the Company's Registered Office, 7, West George Street, Glasgow. Parties to state whether they propose to Tender for one or two years, or for both periods.

Patterns of the General Stores may thereafter be seen at the Company's Addiewell Works, near Westcalder; and Patterns of Lamp Fittings at their Lochrin Works, Edinburgh.

Tenders, endorsed "Tender for Stores," to be lodged with the undersigned on or before Monday, 7th proximo.

The Directors do not bind themselves to accept the lowest or any offer.

Merchants' House Buildings,
7, West George Street,
Glasgow, 17th March, 1879.

JOHN FYFE, General Manager.

ORGANIC MATERIA MEDICA.
By DR. MUTER.

Analytical Chemists will find this a concise and yet complete book of reference for the isolation and examination of the active principles of drugs. Special appendix on the microscopic characters of the starches in food and drugs. Copious index and qualitative courses or resins, &c.

Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, S.E., and sold by Messrs. Simpkins and Marshall and Messrs. Baillière, Tindal, and Cox.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1009

THE ROYAL AGRICULTURAL COLLEGE,
CIRENCESTER.

PROFESSOR CHURCH'S connection with the Royal Agricultural College will, we regret to say, shortly be severed, the only reason being, as far as we can ascertain, that he is about to marry, and therefore will be unable to reside in the College. Seeing, however, that his immediate predecessor was non-resident, we should have thought the Council would have hesitated to adopt this as their reason for depriving the College of the services of so able and experienced a chemist as Professor Church, and we shall look with some eagerness for their explanation of the circumstances.

It appears that at the beginning of February Prof. Church, who has occupied the Chair of Chemistry at the College for the last sixteen years, had an interview with the Principal, the Reverend John Constable, and informed him of his intention to marry during the coming vacation, and of henceforth discontinuing to reside in the College. This intimation the Principal regarded as a resignation of the Professorship, and wrote to Professor Church accepting the resignation. In answer to this letter, Professor Church informed the Principal that if he decided that his Chair became vacant by the fact of non-residence it would therefore become vacant at the date previously mentioned, April 24th. He furthermore assumed that this decision was that of the Governing Body of the College, as he was elected in 1863 under the bye-law then in force, which placed the power of appointing and dismissing Professors in the hands of that body, and not under the twenty-fourth bye-law of 1870 (*vide* CHEMICAL NEWS, vol. xxxix., p. 105), by which this power was vested in the Principal. The matter was then referred to the Committee of Management, and on the 5th of March the following resolution was passed:—

"The Committee of Management are of opinion that the discipline of the Agricultural College cannot be satisfactorily maintained except by the residence of the Professors within the walls of the College in conformity with the original bye-law No. 47. Being fully sensible of the services rendered by Professor Church during his sixteen years' residence in the College, they the more regret that they cannot accede to his recent proposal of non-residence, a compliance with it involving such alterations as would unduly disturb the present organisation of the College staff."

This decision has not only deprived the College of the services of Professor Church, but of those of his two senior colleagues, Professors Lloyd Tanner and Pream, who have respectively vacated the Chairs of Mathematics and Physics and Natural History as a protest against Professor Church's unworthy treatment.

The bye-laws of the College which we published in the CHEMICAL NEWS are perfectly unique in their way, and would seem to show that the Principal entirely supersedes the Committee of Management. He evidently considers that the Students of the College are a set of unruly schoolboys who are only to be kept in order by the strictest discipline, and that the Professors must lead the life of monks. They are not only to devote themselves day and night to the service of the College, but they are to act the much-despised part of the "*pion*," or *maitre d'étude* of a French *Lyce*, and see that their young charges do not tear their clothes, tell fibs, or say naughty words. But as three Professors would have still been left to reside in the College

after Professor Church had left, and as the College has frequently been left in the charge of two, the argument that Professor Church's proposal for non-residence would unduly disturb the present organisation of the College carries with it very little weight.

The consequences of the resignation of three senior Professors, the only University men, by the way, in the College, cannot be otherwise than disastrous. At the end of this term the senior Professor will be a young man, who only two years ago was a student himself, and he will very possibly be called on to rule over students who are his seniors in years, an anomaly which cannot fail to bring about unpleasant consequences sooner or later.

We hear that a new bye-law has just been promulgated for the well-being of the future Professors. They are not to engage in any literary work without special leave from the Principal; in other words, they must take no steps to make a reputation outside the College walls without the express permission of their ruler. Had this rule obtained during Professor Church's Professorship how many valuable contributions to scientific literature would have been lost.

Such restrictions will certainly prevent any man of worth from accepting a position in the College. The Principal may, it is true, gather round him a knot of second or third rate men; but the interests of the College and, indeed, of agriculture generally, must necessarily be injured thereby; indeed, we do not see how the College can escape collapse and ultimate extinction if something is not done either by the Government or the bondholders to prevent such a catastrophe.

On looking over the list of Professors that have formerly occupied Chairs in the College we find that Principal Constable has made no less than twenty-two within the last fifteen years, more by many, we should imagine, than any other man in a similar position has made in his whole life. Professor Church has remained at the College for sixteen long years, but most of the others have left but little trace behind them. Again and again have first class men been engaged, but there has never been any inducement held out to them to cast in their lot with the College.

A contemporary gives the Principal the credit of having made the College pay, the bondholders having of late received a four per cent dividend, and something has been done towards paying off the loan, but this has only been accomplished by raising the fees from £90 to £126, by discontinuing the farm which some authorities consider to be a breach of the provisions of the Charter, the sale of the steam plough, and the most pernicious economy in every direction. Nothing is spent on the Museum, and nothing in several departments for specimens and apparatus. To have a good surplus every year is no doubt gratifying to the Council and bondholders, but even gold may be purchased at too high a rate.

We feel sure, in conclusion, that our readers will join us in expressing our sincere sympathy with Professor Church and his colleagues at thus having to sever themselves from an institution with which they were so long connected, and to which they had rendered such valuable services, as well as in paying a just tribute of admiration at the manly, straightforward, and honourable course they have taken.

Progress Effected in the Preparation of Colours Derived from Coal.—Adolphe Kopp.—The attempts made to dispense with arsenic in the manufacture of magenta have only been partially successful. The process of Coupier, who causes nitro-benzol to react upon a mixture of aniline and toluidin in presence of hydrochloric acid, is adopted in some manufactories, but it offers serious difficulties which interfere with its general employment. It is more costly and more difficult manage.—*Moniteur Scientifique*.

FILTER-PRESSES FOR CHEMICAL WORKS.

By J. MARZELL.

In this time of depression of trade it is natural that chemical manufacturers should pay more attention to those kinds of apparatus which, by a surer and better working, enable them to increase the yield, and permit quicker passing through the intermediate stages of the processes, thus giving to a plant a higher working power and efficiency. Among that class of machinery the so-called "filter-presses" undoubtedly hold one of the foremost places, and their being taken up so rapidly—especially in the last year—surely speaks in their favour.

The principle of the filter-presses is generally known; it is a filtering under pressure, for the object of—

- (a) Filtering the largest possible quantity of fluid—consequently solids—in comparison—through the smallest possible filter space.
- (b) Freeing the residue remaining in the filter as much as possible from the filtrate.

Both points are realised by the pressure applied in filling the filter-presses, and generally amounting to 120 lbs. per square inch. At the same time the filter-press represents the most convenient arrangement of filter cloth, as a very large surface is brought into a very small space. In the largest size presses over 425 sq. feet effective filtering surface are arranged in a box, if I may call it so, of $4\frac{1}{2}$ sq. ft. to 9 sq. ft. General rules of yields cannot be laid down, as specific gravity and physical properties of the different stuffs are important points to deal with. The greatest difficulty for chemical works always was to find a press suiting the different stuffs and operations, as these in most cases cannot be altered or modified without losing on the other side all advantages the filter-presses might have promised. It was therefore only natural that the massive and enormous wooden cubes brought out at first, with their elaborate handling, had soon to make room for lighter constructions, with a number of improvements in many directions.

An important improvement has recently been made by M. A. L. G. Dehne. I refer to a new arrangement for an absolute outwashing of the press cakes in the press itself under the following conditions:—

- (a) To use as little wash water as possible.
- (b) To remove the last traces of soluble substance out of the cake, to wash absolutely or completely—be it either to wash the cakes, as the valuable part "neutral," as I may term it (as required with alizarin, tartrate of lime, blanc fix, &c.), or to separate the valuable soluble substances from the worthless residues without any loss, and to get the wash liquors in a concentrated state, the latter being of great importance for a following concentration for crystallisation (as with sugar, citric, tartaric acids, alum, sulpho-salts, &c.)
- (c) To do all that in the shortest time possible.

In the old method of washing the water was introduced on the top of the cakes, trickling through the same, taking up in its way the soluble substances it met with, and leaving the press by the cocks. Every manufacturer acquainted with these presses will have found that it takes a long time, and is seldom possible, to remove the last parts of soluble stuff, and therefore it was preferred in many cases to take out the cakes, boil them up with water, and to re-filter-press them; in many cases even repeating the operation several times.

The reason of this improper acting of the washing apparatus is the insufficient distribution of the wash liquor in the cakes, caused—

- (a) By the construction.
- (b) And principally, by the air enclosed in the cakes.

Especially is this last point of great importance. That the amount of air in the cakes is consider-

able is proved by the fact that in the manufacture of china and faience the cakes of clay coming out of the presses never can be used on the chairs before having passed cutting and kneading machinery, as in baking the air would form bubbles on the goods. In the washing process the air prevents the wash liquor from a thorough penetrating of the cakes. The water coming from above would not remove but only dislodge the air. The consequence of that was the conclusion to let the wash liquor enter at the bottom and make its way upwards, driving thus the air before it, which is removed by a system of air channels and escapes, with a whistling noise, out of a mouthpiece.

The other disadvantage of the old system was the following:—The water entered on the upper edge of the cake in two streams of about $\frac{1}{2}$ in. thick. By the pressure the washing was applied and the two streams naturally tried to find the most direct way to the outlet, and that is the line drawn from their point of entrance to the outlet cocks! Besides that, the way was regulated by the little air-bladders forming a regular kind of network in the cake. The result was that the streams, instead of equally impregnating the material, only parted themselves in the cakes, so to say, forming a system of small rivers, the islands of which never came under the influence of the water.

To do away with this irregularity M. Dehne covered the channelled surfaces of the press plates inside; the chambers with perforated sheets of metal, and now in washing brought the water into the space formed between the channelled surface and the perforated plate. Thus on both sides of the cakes in this way walls or plates of water are produced, which by the hydraulic acting pressure are driven diametrically into the cakes. With a cake of 1 in. thick the water has only to move $\frac{1}{2}$ in. to join the liquor coming from the other side. As the air has been removed beforehand, each molecule of the stuff in the presses is now brought into contact with the water, which thereby has full power to take up all soluble particles. The arrangement allows at the same time to regulate the pressure under which the extraction takes place.

So far the theory. The practice, by working on large scales under different circumstances and with different materials, has given the best results.

As example I give the returns of the K. K. Zuckerfabrik Swolonowas (Austria), which were kindly placed at my disposal. The material is the product of precipitating saccharate of lime with carbonic acid, thus yielding carbonate of lime, mixed with sugar syrup, which latter has to be removed.

"The presses are such with 18 chambers of M. Dehne's, showing 125 square ft. filtering surface proved for 120 lbs. per square inch."

Filling of press = 30 minutes; washing absolutely = 18 minutes; emptying and starting = 6 minutes; together 54 minutes.

The weight of the extracted cakes out of one press, 315 lbs. (157 k.); the cakes are hard.

The extracted cakes were *entirely free from sugar*.

The quantity of wash-water used for one press = 39 gals. (176 litres). Density of the entire wash-liquor = 5.23° balling and 4.11 per cent sugar.

The filter cloth has not to be removed for a fortnight. (This for the reason in the arrangement that the wash-liquor takes the opposite way of the filtration, thus always cleaning the pores of the cloth.—J. M.) The firm receives daily 13½ tons (13,627 k.) of the washed-out residues. The corresponding residues of the old presses retained about 2.46 per cent of sugar, which it was not economical to regain, and the firm reckon the *net gain* they have by putting up Dehne's new presses with absolute extraction with 47½ tons (47,400 k.) of sugar in a campaign of 150 days, representing a value of £1422 (14,220 Austrian florins).

The quicker working and the advantage of getting pretty

concentrated liquors into the evaporating pans need not be mentioned.

Another example. The quick extraction of valuable cakes is given in the manufacture of the artificial alizarin material; alizarin paste must be freed from the sulphate of soda. With the old presses the washing was going on twelve to fourteen hours before the charge of a press with 18 chambers was finished. The new presses with absolute extraction—according to the returns of an alizarin works using twelve of these new presses—only wanted 35 to 45 minutes for the absolute neutralisation of a properly precipitated paste. In this case a secondary but important advantage of the new process can be seen. In washing there is always some alizarin taken up into suspension and washed away, especially in the last hours, when the water is running pretty clear. As with the new presses the time, as well as the quantity of water, are decreased considerably, this loss is reduced to a minimum. Of great weight this point is in the treatment of such substances, which themselves are slightly soluble in water. I only mention tartrate of lime.

Notwithstanding their short life the new presses with absolute extraction have been taken up by a great many firms. Like most new things they have often to meet with mistrust and criticism in sometimes the most incomprehensible form. From the representatives of progress, however, "the go ahead people," the new apparatus everywhere meets with the greatest interest and acknowledgment of its practical advantages, and the large number of these presses already delivered to various branches of different countries may be proof of their value.

41, Woburn Place, London, W.C.

ON INDIGO-BLUE FROM POLYGONUM TINCTORIUM AND OTHER PLANTS.

By EDWARD SCHUNCK, Ph.D., F.R.S.

(Continued from p. 120).

THE preceding experiments lead to the conclusion that the leaves of *Polygonum tinctorium* contain a substance not to be distinguished from the indican of *Isatis tinctoria*, which by decomposition with acids, yields indigo-blue and glucose, accompanied by some by-products, and that there is no proof of the existence of ready-formed colouring-matter in the plant while the latter is living and in a healthy state. The pre-existence of indigo-blue, or of its hydride, indigo-white, in these plants was taken for granted forty or fifty years ago when the class of bodies which we now call glucosides and the peculiar kind of decomposition which they undergo were unknown. Even now a superficial examination of some phenomena would almost certainly lead to the conclusion that the indigo-blue is formed by the action of air, i.e. in consequence of the oxidation of some easily oxidisable substance in the plant. Bearing in mind, however, with what extreme facility indican is decomposed, its watery solution on standing some time, even at the ordinary temperature, depositing indigo-blue, I think it will not be difficult to explain all the phenomena hitherto observed by myself and others.

On taking a plant of *Polygonum tinctorium* and making incisions with a penknife in the leaves between the main vessels, or crushing the soft parts of the leaves here and there with an agate pestle, then, after a short time plunging the whole plant into boiling alcohol to remove the chlorophyll, it will be found that those parts of the leaf which have not been injured, become white or retain only a faint yellow tinge, while those parts that have been cut, crushed, or otherwise injured, show a blue colour, the colouration extending for some distance inwards from the place where the lesion occurred, the most intense colour

being at the edge of the cut or bruise. So, too, in the living plant, when some injury accidentally occurs to a leaf, the part injured will appear blue. Nothing can be more natural than to suppose that in these cases the blue colouring-matter is formed by the action of the air, i.e. by the oxidation of some substance which escapes from the cells in consequence of organic lesion, just as the surface of a freshly cut apple or pear becomes brown on exposure.

If a plant of *Polygonum tinctorium* be immersed in water, and the water be frozen by surrounding the vessel containing it with a freezing-mixture, it will be found, after complete thawing, that the leaves or parts of leaves which have been thoroughly frozen appear of a dark colour and are quite flaccid; and if the plant be then immersed in boiling alcohol so as to dissolve the chlorophyll and other matters, those very parts show afterwards an intense blue colour, while those portions which had remained unfrozen appear almost colourless. This experiment, which had already been made by Joly, was considered by him to prove the pre-existence of indigo-blue in the plant—though why, if this were the case, the colouring-matter should not make its appearance in the unfrozen portions of the leaf, I am at a loss to understand.

The fact that a fresh leaf of *Polygonum tinctorium*, if immersed in alcohol or ether, appears blue after the chlorophyll has been removed, has also been considered to prove the pre-existence of indigo-blue in the cells. This phenomenon is always observed when the leaves are immersed in cold alcohol, and more distinctly when ordinary spirits of wine are taken than with absolute alcohol. A very simple experiment suffices, however, to prove that in this, as in all the other cases, appearances are deceptive. If freshly gathered leaves of *Polygonum tinctorium* are plunged at once not into cold, but into boiling alcohol, the whole of the colour is soon removed, the leaves retaining only a faint yellow tinge. On now simply evaporating the green alcoholic liquid, not a trace of indigo-blue will be found in the residue. It is therefore absolutely certain that the leaves contain no ready-formed colouring-matter; for so stable a body as indigo-blue could not possibly be decomposed or be made to disappear by the action of boiling alcohol only. It must necessarily appear either in the alcoholic extract of the leaves or in the residual portion left by the alcohol.

A very simple explanation offers itself, I think for all the phenomena hitherto observed. Indican, the mother substance of indigo-blue, is a body the molecules of which are in a state of unstable equilibrium. As long as it is contained within the cells of the plant the vitality of the cells keeps it in its original unchanged condition. As soon, however, as this vitality is destroyed (whether by organic lesion, by extreme cold, or by any other means), the indican begins to undergo decomposition, the molecules rearrange themselves in the order to which their chemical affinities predispose them, and the compound splits up into indigo-blue and indigluceine, this taking place so rapidly that in certain cases it would appear as if the colouring-matter pre-existed in the plant. If (to take the simplest case) the leaves as soon as gathered are immersed in cold spirits of wine or in cold ether, the vitality of the cells is thereby destroyed; and the indican contained in them is then in part decomposed, yielding indigo-blue, which remains undissolved, imparting a more or less distinct blue tint to the leaves. When boiling spirit of wine is taken, the indican is extracted before it can undergo decomposition, and dissolves in the spirit. It may be detected in the residue obtained on spontaneous evaporation of the alcoholic extract by its property of yielding indigo-blue on decomposition with acids as above described. It is possible that the leaves contain some ferment which hastens the decomposition of the indican as soon as vitality has ceased; but I have no positive evidence to offer in favour of this view.

I may, in conclusion, describe another experiment, which, though it teaches nothing new, confirms what I have just stated, and is interesting in its way. Having cut some

sprigs of *Polygonum tinctorium*, about six inches long, I immersed the cut ends in dilute hydrochloric acid (consisting of one part of acid of specific gravity 1.15 and ten parts of water), and left them to stand for several days exposed to the sun and air. The acid was gradually absorbed, ascending through the stems, first into the lower leaves, then into the higher ones. The gradual absorption of the acid was distinctly seen by the discolouration of the leaves, which commenced at the basis of each leaf and extended towards the apex, the lively green colour being changed into a dirty yellow. After some time this colouration was followed by a dark blue one, commencing at the base of each leaf and extending towards the apex, but never quite reaching the latter except in the lower leaves. When the change in colour had begun to show itself in the upper tenderer leaves, the whole showed symptoms of fading, all further power of absorbing the acid liquid seemed to be lost, and the sprigs were then at once immersed in hot spirit of wine. After remaining in the spirit until the chlorophyll was removed, the part of each leaf which had undergone a change appeared blue, whilst the part into which the acid had not penetrated appeared almost colourless. In this case it is probable that the indican was decomposed not so much in consequence of the loss of vitality in the cells as by the direct action of the acid. In some of the leaves there was another distinct blue colouration towards the apex, in the part to which the acid had not penetrated, separated from the blue part at the base by a white zone. This second colouration may be attributed to the loss of vitality in that part of the leaf.

All these experiments must be made with plants whilst in a state vigorous growth. If made when the season is advanced (that is, after the flowers have begun to appear), the leaves, though apparently unchanged, show only traces of blue colour after treatment and subsequent immersion in hot alcohol. This shows either that the indican has disappeared, being applied to other purposes in the economy of the plant, or that it has undergone the peculiar molecular change before referred to, into a substance which no longer yields indigo-blue by decomposition, but indirubine and other products. The latter is the more probable way of accounting for the difference; for the parts of the leaf which have been accidentally injured by the bites of insects or from other causes at the later stage of the plant's development become red, not blue, as at the earlier stages. This red colour disappears on immersion of the leaves in hot alcohol, the indirubine, to which it is probably due, being more soluble in that menstruum than indigo-blue.

The leaves of *Polygonum tinctorium* in which the blue colour has been developed by any of the means described, exhibit even to the naked eye, and still more distinctly when examined under the microscope, certain appearances which are not without some interest.

1. The colouring-matter seems to be confined to the parenchyma of the leaf. The stem and its fibrous ramifications in the leaf are free from it, so that in the coloured leaf the vessels may be distinctly traced as white veins on a blue ground. Even the cells of the parenchyma adjacent to the vessels are much less coloured than those a little further off, which produces the effect of a gradual shading of colour from the white of the vessels to the dark blue of the remoter cells. The cells of the leaf-cuticle are also free from colouring-matter.

2. The younger leaves at the summit of each branch generally show a more intense colour than the older ones near the base. Each leaf probably contains the same amount of colouring-matter; but in the lower leaves it is more widely distributed.

3. The intense and apparently uniform colouration of some of the leaves might lead to the conclusion that the cellular tissue is itself dyed blue—which would not seem improbable considering the affinity which indigo-blue shows for cellulose, as seen in the blue-dyeing of cotton fabrics. On examining the leaf-cells under the microscope,

this is found, however, not to be the case. The colouring-matter is discovered within the cells of the parenchyma in the shape of separate dots and parcels of various sizes, and apparently in an amorphous state, the cell-wall being quite colourless. These dots and parcels being very numerous, produce, when seen in the mass, a uniform blue colouration, more or less intense. The darker colour of some leaves is simply the effect of a greater crowding of the blue particles in each individual cell, the cells of the paler leaves containing fewer of these little masses, sometimes hardly any.

Mr. Charles Bailey, to whom I gave some specimens of leaves of *Polygonum tinctorium* coloured blue, had the kindness, at my request, to submit them to microscopic examination, and gave the following as his opinion thereon:—

"The colouring-matter left in these specimens would seem to be what Nägeli terms 'crystalloids;' and, with one exception, these bodies are, as far as my examination has gone, confined to the interior of the cells of the parenchyma. I do not see the least trace of any of this colouring-matter occurring in the intercellular spaces. The only part of the tissue where I find it, other than the parenchyma, is in the cells of the stomata; but it occurs nowhere else in the cuticle."

(To be continued.)

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, March 20, 1877.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

AFTER the announcement of visitors the minutes of the previous meeting were read and confirmed. The following certificates were read for the first time:—W. Johnstone, W. B. Turner, C. Slater, T. Palmer, A. H. Black, W. A. Bradbury.

THE PRESIDENT then called on Dr. FRANKLAND to read a paper on "*Plumbic Tetrethide*," by E. FRANKLAND and A. LAWRENCE. This substance was discovered by Buckton in 1859. The authors prepared the compound as follows:—Plumbic chloride is added to zinc ethyl contained in a stout glass bottle as long as any reaction takes place. The product is mixed slowly with a large volume of water, and distilled (from an oil bath) in a current of steam. The distillate separates into water and a heavy layer of plumbic tetrethide. During the preparation no gas was evolved, and the authors infer that the decomposition has two stages, $PbCl_2 + 2ZnEt_2 = PbEt_2 + 2ZnEtCl$ and $2PbEt_2 = Pb + PbEt_4$. The following gases have no action at ordinary temperatures on plumbic tetrethide:—Ammonia, carbonic anhydride, carbonic oxide, cyanogen, nitric oxide, oxygen, sulphuretted hydrogen. Sulphurous anhydride is rapidly absorbed and the liquid plumbic tetrethide converted into a white amorphous solid. This product was placed in a beaker, over which was inverted a second beaker, the two being luted with gummed paper. On heating the lower beaker with steam, crystals sublimed, which, after purification from a volatile lead compound by treatment with strong nitric acid, evaporation to dryness, and re-crystallisation from alcohol, proved in chemical composition and physical properties to be identical with diethyl-sulphone, SO_2Et_2 . The residue after the sublimation of the diethyl-sulphone consisted principally of plumbic ethyl-sulphinate,

Ethyl-sulphinic acid may be considered as sulphurous

acid, SOHO_2 , in which a semimolecule of ethyl has replaced one of hydroxyl, SOEtHO , or as propionic acid in which one atom of tetrad-sulphur has been substituted for one of carbon—

No volatile organo-metallic base was detected in the product of the action of SO_2 on PbEt_4 similar to that produced in the corresponding reaction with stannic ethide.

In answer to a question of the PRESIDENT,

Dr. FRANKLAND said that plumbic tetrathide could be prepared directly without the intervention of zinc ethyl, but the product was small in quantity and impure.

Prof. W. FOSTER then gave a verbal communication "On the Production of the Higher Oxides of Iron, Chromium, Manganese, and Bismuth." Prof. Foster said that the observations he had to make were a continuation of a paper which he had recently communicated to the Society. When a strongly alkaline solution of sodic hypobromite is heated with a solution of potassic ferrocyanide the solution rapidly becomes deep red from the formation of a ferrate. Almost any iron compound, and even freshly precipitated ferric hydrate can be substituted for the ferro-cyanide in the above reaction. The author has not attempted to isolate the potassium or sodium ferrate formed under these circumstances. Similar reactions occur if manganese, chromium, or bismuth compounds be boiled with alkaline hypobromite, permanganate, chromate, &c., being formed. Oxygen is evolved during the reaction. Cobalt, nickel, and copper salts also evolve oxygen. The author demonstrated this fact in the case of cupric sulphate, a considerable quantity of oxygen being collected when the sulphate was mixed with alkaline hypobromite, and the mixture heated to about 20°C .

Dr. WRIGHT said that some samples of bleaching-powder when closely stoppered were apt to explode: (he had always found manganese in these samples). Possibly this might be accounted for by the evolution of oxygen by a reaction similar to that described by the author.

Mr. NELSON asked if Prof. Foster had noticed any formation of a green manganate in the oxidation of manganese compounds. Some time since he was working with ferrates, and obtained once a green iron acid which he had never seen since. Perhaps by these reactions it might be obtained.

Mr. HARTLEY had noticed that when the copper sulphate and alkaline hypobromite were first mixed the solution turned yellow, but when the evolution of oxygen ceased the liquid was quite dark. This yellow substance was probably Brodie's cupric peroxide.

Mr. KIMOSSETT had made some experiments on the action of oxide of manganese on bleaching-powder; oxygen was evolved, but the gas was not pure.

Prof. FOSTER, in answer to a question of the President, said that he had not tested the oxygen evolved quantitatively as to its purity.

The next paper was read by the SECRETARY, "On the Decomposition of Water by certain Metalloids," by C. F. CROSS and A. HIGGINS. The statements of chemists with respect to the action of sulphur on water are conflicting. Mulder affirms that the vapour of water reacts on sulphur at a high temperature to form penta-thionic acid. Myers asserts that hydrogen sulphide and thio-sulphuric acid are formed. Girard also found that hydrogen sulphide was evolved by boiling sulphur with water. Geis ascribes this evolution to impurities in the sulphur. The authors therefore investigated the reaction of sulphur with water. Water containing "flowers of sulphur" in suspension was boiled, and the vapour conducted into lead acetate. The latter was continuously decomposed with the formation of sulphide. The quantity formed under various conditions was estimated. The reaction which occurs is probably $2\text{H}_2\text{O} + \text{S}_2 = 2\text{H}_2\text{S} + \text{SO}_2$. If air be present sulphuric acid is also formed. Some experiments

were also made with sealed tubes. The authors conclude that sulphur decomposes water, uniting both with its oxygen and hydrogen, the decomposition being independent of atmospheric oxygen. The authors repeated their experiments with sulphur purified by treatment with potassium permanganate, and find that the reactions above described remain unaltered. Selenium and tellurium have an appreciable action on water at 160° . Amorphous phosphorus does not decompose water at 100° . At 160° a small quantity went into solution. When lead acetate solution was substituted for water, metallic lead, phosphate, and phosphide were formed. With copper sulphate metallic copper was deposited with phosphide and sulphide, phosphoric and sulphuric acids being also formed; cupric chloride at 160° is first reduced to cuprous chloride, and finally converted into a phosphide. Vitreous phosphorus does not decompose boiling water except in the presence of oxygen; it reduces metallic (lead acetate) solutions even when oxygen is excluded. Bromine and iodine, when heated with excess of water, dissolve in small quantity as alkaline bromides, bromates, &c. If bromine be treated with lead acetate, lead bromide and dioxide are formed.

Mr. WARINGTON remarked that an Italian chemist had observed that gypsum was formed by the action of calcium carbonate on sulphur in the presence of moisture.

The next paper was read by the SECRETARY, "On the Volumetric Determination of Chromium," by W. J. SELL. The author having discovered that chromium in ordinary chromic salts can be completely converted into chromic acid by means of potassic permanganate, endeavoured to apply this reaction directly for the estimation of chromium. He was, however, unsuccessful, owing to the separation of manganese dioxide. He has devised the following method, which yields rapid and accurate results. The solution, containing chromium acidified with sulphuric acid, is boiled, and a dilute solution of permanganate added to the boiling liquid until a purplish tint remains after boiling for three minutes. The solution is then rendered slightly alkaline with sodic carbonate, alcohol is added, and the manganese filtered off. The chromic acid in the filtrate is estimated by titration with iodine and sodic thio-sulphate. The author has successfully applied the method to the estimation of chromium in chrome iron ore. He recommends the following plan of effecting its decomposition. The chrome iron ore is placed on the top of about ten times its weight of a mixture composed of one molecule of well-fused and powdered sodium bisulphate to two molecules of sodium fluoride, and the whole is ignited for fifteen minutes. An amount of sodium bisulphate is now added equal to that of the mixture taken, and when thoroughly fused a further addition of an equal quantity of bisulphate is made, the mass fused, and then rapidly cooled. The fused mass so obtained dissolves completely in boiling water acidified with sulphuric acid. In this way a determination can be made in an hour and a quarter. The author's attention has been directed to a notice by Mr. Wanklyn in the *Phil. Mag.*, February, as to the conversion of chromic oxide into chromate by alkaline permanganate. This result the author arrived at some months ago, but has not yet succeeded in applying it quantitatively.

During the reading of the last paper Dr. RUSSELL occupied the Chair.

The anniversary meeting will take place on Monday, March 31. The next ordinary meeting will be on April 3, when the following papers will be read:—"On Terpin and Terpinol," by Dr. Tilden; "On the Transformation of Aurin into Trimethyl-para-rosanilin," by R. S. Dale and C. Schorlemmer; "On a Gold Nugget from South America," by Mr. Attwood; "On the Solution of Aluminium Hydrate by Ammonia, and a Physical Isomeride of Alumina," by C. F. Cross.

PHYSICAL SOCIETY.

Ordinary Meeting, March 22, 1879.

Prof. W. G. ADAMS, President, in the Chair.

New member—Capt. Hastings R. Lees, R.N.

Capt. ABNEY, R.E., F.R.S., read a paper "*On Obtaining Photographic Records of Absorption Spectra.*" Absorption spectra have hitherto been recorded by the difficult process of hand copying; but the discovery by Capt. Abney of a silver salt sensitive to all rays in different degrees renders the photographic method available. The records thus obtained are photographs of the spectrum of the naked light of the source, and of that of the same light reduced by insertion of the absorbing material in its track, and these are taken parallel, so that the dark absorption lines can be readily compared. Examples of these were thrown on the screen. This method can be used as a new weapon in attacking solar physics, and determining whether or not compound bodies exist in the sun. Absorption spectra to compare with the sun's can be got for compound bodies by burning the matter in question in a flame in front of the slit, and passing a bright light through the flame.

Prof. GUTHRIE, F.R.S., then read a paper "*On the Fracture of Colloids.*" as illustrated by experiments on the breakage of glass plates either by pressure or heating at the centre or round the circumference. Circular plates of glass pressed at centre or circumference break in radial lines. However supported a plate breaks in the same fashion if heated in the same way. If heated in the middle the crack is peak-shaped, like an obelisk on a double pedestal, two cracks forming the outline, with sometimes a third down the middle. The two cracks unite before they reach the edge on one side, and (as afterwards pointed out by Prof. W. G. Adams) the three extremities of the two cracks all meet the edge at right angles to it. The crackage varies with the size and shape of the plates, the flame, and kind of glass; but the type is the same for all. Cracks cross each other. Prof. Guthrie defined a crack as the line where the ratio of cohesion to strain is least, and likened it to the lightning flash.

Mr. W. CHANDLER ROBERTS, F.R.S., said that he had observed once a volute spiral crack in dried hydrated silicic acid, and recommended Prof. Guthrie to study cracks in agate, which is the most perfect colloid known.

NEWCASTLE CHEMICAL SOCIETY.

Mr. J. W. SWAN in the Chair.

THE minutes of the previous meeting were read and confirmed.

Mr. John Cliff was elected a member.

The following names were read for the first time:—Mr. James C. Rollin, 1, St. Nicholas' Buildings, Newcastle-upon-Tyne; Mr. Thomas Douglas, Blaydon Manure Works, Blaydon-on-Tyne; Mr. Alfred Poole, Bottle Works, Blaydon-on-Tyne; Mr. W. F. Vint, Chemical Works, Seaham Harbour.

The CHAIRMAN, in drawing attention to the collection of apparatus sent for exhibition, alluded to the difficulty which had always been experienced in getting the meeting immediately preceding Christmas satisfactorily filled in the usual manner—a difficulty which had led to exhibitions of little novelties such as were then before the meeting, and to the passing the evening in a less formal and more social manner. The secretaries had been in correspondence with such friends as they thought likely to contribute objects of interest, including Messrs. Aug. Bel and Co., from whom they had been hoping till the last day to receive M. Cailletet's apparatus for the condensation of

gases, which in itself would have been ample attraction for the meeting; but, unfortunately for the Society, it was still in use at the Royal Institution, and in consequence could not be spared; but in the absence of this great attraction, there were yet objects that would repay examination, and he invited Mr. Starks to describe the mode of using the apparatus for estimating free oxygen in a mixture of gases, and the two forms of nitrometer.

The following notes, descriptive of the apparatus, were read:—

"*Apparatus for Estimating Free Oxygen Volumetrically,*" by Messrs. MAWSON and SWAN.

The accompanying sketch represents a simple and convenient apparatus for the rapid and correct volumetric estimation of oxygen when mixed with other gases. It consists, as will be seen, of a measuring tube, A, holding from 0 to the three-way tap 100 c.c., and graduated in the

lower narrower portion into c.c. and tenths; of an absorption arrangement, B, which is a glass bell in which is placed a coil of copper gauze, suspended in an outer glass vessel which contains the absorbing liquid; a three-way tap, C, which serves to communicate between the measuring and absorption tubes, or with either and the external atmosphere; and of a globe, D, which serves the purpose of drawing the gas for examination into the measuring tube, and chasing it backwards and forwards between the measuring and absorption tubes. The solution used to absorb the oxygen is made of two parts of a saturated solution of chloride of ammonium and one part of liquid ammonia, s.g. 880. For an examination, the vessel, B, having been about two-thirds filled with the ammonium solution and sufficient water put into D to fill the measuring tube, expelling the air by the vertical outlet, C, the tap, C, is opened so as to make communication between A and B; D is then lowered so as to fill the glass bell and tube

above it is as far as the tap with the ammonium solution, then close c on the side b, and open the vertical outlet; d is then raised so as to fill the measuring tube with water up to the tap; the vertical outlet is now connected with the gaseous mixture to be examined, and by again lowering d the gas is drawn into the measuring tube to c, when exactly 100 c.c. will be present for examination; now turn c so as to make communication again between a and b, and chase the gas backwards and forwards by the raising and lowering of the glass vessel, d, two or three times, finishing by bringing the gas back to the measuring tube, and the absorbing solution to the original starting point; lastly, close the three-way tap altogether, and bring d down so that the two water levels in d and a coincide, when the reading of the liquid in a will give the percentage of oxygen that has been absorbed. By using other solutions it is obvious it may be used for the examination of other gases.

"Dr. Lunge's Nitrometer for Determination of Nitrous and Nitric Acids," by Messrs. MAWSON and SWAN.

The method of using is thus described by Dr. Lunge:—You will observe the measuring tube, a, holding 50 c.c., divided in $\frac{1}{10}$ ths, provided with a funnel, c, and a two-bore glass cock, b, hanging in an instantaneously-opening

spring clamp; an elastic tube connects a with the plain tube, b, of equal size, sliding up and down in another clamp. First of all, b is placed so that its lower end is nearly at a level with d; mercury is poured into b till it has filled a and has got into c; d is turned so as to close the communication between a and b, and so run off the excess of mercury through the lateral bore; b is lowered in its clamp, and 1 c.c. of the nitrous vitriol, &c., to be tested is introduced into c by means of an accurate pipette. By carefully turning d, the acid is sucked into a without any air following, and c is rinsed out by a few c.c. of pure acid, run into a in the same wa-

A is now taken out of the spring clamp, violently shaken for two minutes (no more is necessary), replaced in the clamp, and b adjusted, so that the levels of mercury of both tubes are equal, except that an allowance is made in b for the acid contained in a, $\frac{1}{10}$ th of the height of the latter being either allowed for as an addition to the mercury in b, or else being deducted from the barometrical pressure. After the temperature has become constant (quarter of an hour suffices for factory work, one hour for exact analyses), the volume of gas in a is read off (which can be done to $\frac{1}{10}$ c.c.) and reduced to 0° and 760 m.m. in the usual way. Each c.c. at 0° and 760 m.m. corresponds to 1.343 m.gr., NO = 1.701 m.gr., N_2O_3 = 2.417 m.gr., N_2O_5 = 3.805 m.gr., NO_2Na , &c. Now d is opened so that a and c communicate, b is raised, and thus first the gas then the acid are driven into c, from whence the acid is run away by the lateral bore of d; everything is now ready for a new test.

"Model of Modern Blast-Furnace," by P. A. BERKLEY.

MR. P. A. BERKLEY exhibited a model of a blast-furnace, which he said appeared to give the most satisfactory results in working, producing about three times as much iron per week as the old forms of furnace, and had not been surpassed by furnaces of either larger or smaller dimensions. It had worked incessantly since 1872. The model was accompanied by the following note:—

The model shows section through middle, with the various charges of iron ore, limestone, and coke, made to the scale of $\frac{1}{4}$ inch equal 1 foot. The counterpart of this furnace is at Jarrow. It is 85 feet high, 26 feet bosh—nearly 30,000 cubic feet capacity. It is blown by 5 tuyeres, 5 inches and $5\frac{1}{2}$ inches in diameter, with blast at a pressure of $4\frac{1}{2}$ lbs. and heated up to about 1200° F. The heat for the blast is raised from the waste gases from the furnace, as well as the steam for working the blast engine. This furnace is making 500 tons of pig-iron per week, in the making of which it consumes about 1750 tons of Cleveland iron-stone, or other ores equivalent thereto, 587 tons of coke, and 300 tons of limestone. The furnace was erected in 1872, for Messrs. Palmer and Company, by Mr. Philip A. Berkley, the Company's Engineer and Blast-Furnace Manager.

A brief discussion followed, in which Messrs. Hill, Morrison, Berkly and the Chairman took part.

(To be continued).

NOTICES OF BOOKS.

Ozone in Relation to Health and Disease. (An Address delivered before the Congress of the Sanitary Institute of Great Britain, held at Stafford, 1878.) By HENRY DAY, M.D. London: J. and A. Churchill.

IN this Address the author gives us the history of the discovery of ozone, and notices the successive theories of Schöenbein, Williamson, and Odling concerning its nature. He then describes the pathological action of this form of oxygen, and reveals facts which will probably startle those who believe ozone and "ozonised" articles of food or of medicine to be universally beneficial. He describes the death of animals after exposure to ozonised air under symptoms closely resembling those of acute bronchitis. He considers that if present in excess in the atmosphere, catarrh, bronchitis, and even pneumonia would be its natural results. Whether there is ever such an excess as would involve these consequences is an open question. He feels also bound to admit, according to the researches of Dr. Moffat, that during "ozone periods" apoplexy, epilepsy, vertigo, neuralgia, and diarrhoea are more frequent. Further investigations in this direction are imperatively needed, but what has been said may serve as a caution to dabblers in science who keep an ozone apparatus in action in their sitting-rooms as a prophylactic against diseases in general.

The absence or the deficiency of ozone has been, perhaps, too hastily placed in connection with zymotic disease. But that such a connection exists in case of cholera can scarcely be doubted. The author shows that in 1864 in the Bombay Presidency, cholera was in its greatest ascendancy when ozone was either wanting or at its minimum; that the disease showed a most marked decrease when ozone was registered as increasing, and when at its maximum the epidemic ceased altogether if the maximum continued for any time. Similar results were obtained at Strassburg in 1854 and 1855, and the experiments of Mr. Glaisher and of Dr. Moffat give confirmatory testimony. Whether there may be other causes in operation in addition to deficiency of oxygen is still doubtful. As a disinfectant the author pronounces it the best, safest, and least objectionable known. That it may kill disease-germs—whatever they may be—is no doubt highly probable from its action on the superior animals; but the question arises, Which will be killed first? We are somewhat surprised at finding in this address no reference to the well-known and justly admired work of Dr. C. B. Fox.

CORRESPONDENCE.

THE INSTITUTE OF CHEMISTRY.

To the Editor of the Chemical News.

SIR,—The long time that elapsed between the date of the Conference and the issue of the report to the members of the Institute, as alluded to by your correspondent "An Appeased Promoter," was caused chiefly by the decision to send it out together with the annual report of the Council.

The financial position of the Institute at the present time is excellent, but I fear few people would consider it to be such if the Council were to follow your correspondent's advice and "spend the large sum they have in hand," especially when it is remembered that our investment in consols does not cover the Life Compositions and Entrance Fees received up to the present. I do not for an instant suppose that "An Appeased Promoter" desires this to be spent. A man who lives up to his income is a poor man, however large his income may be, and this saying applies to corporations as well as to individuals. If, however, your correspondent thinks that the Council has left anything undone which it ought to have done, and will send me any suggestions, I can safely promise that they will have the most careful consideration from the Council.

In conclusion let me thank "An Appeased Promoter" for his frank reply, and at the same time to express a wish that he had not written anonymously, as it would have enabled me to have answered his first letter more satisfactorily, and have saved valuable space in these columns occupied by Yours, &c.,

CHAS. E. GROVES, Secretary.

Somerset House Terrace, W.C., March 22.

TENACITY OF STARCH.

To the Editor of the Chemical News.

SIR,—In reply to Mr. Thompson's letter (CHEMICAL NEWS, vol. xxxix., p. 122) I beg to say that the method for determining the tenacity of starch is not intended to determine the tenacity of a sample of British gum or the relative tenacities of British gum and starches, but only to compare samples of starches with each other. When I devised the method I conducted some experiments on the starches found in the market. I found that when equal weights of the different samples of starch were boiled with equal quantities of water and pieces of cloth of equal size starched with the different samples, that those samples which had the greatest tenacity gave the stiffest cloth.

Any of your readers can try this by procuring samples of Coleman's and Glenfield's starch weigh equal quantities, and boil with equal quantities of water and starch two pieces of cloth of equal size, *without squeezing out the excess of starch*, and dry; the touch will be able to determine which is the stiffest. Mr. Thompson says: "and weight for weight the farina which possesses the least 'tenacity' would produce the greatest stiffness, because the thinner the sample boils the more easily will the solid matter be able to enter the fibre, and it will enter in greater quantity." In the process of sizing when the yarn has passed through the size trough and got saturated with the size (say starch) it passes between two rollers, which squeeze out the excess of size. Now, although the thinner sample may enter the fibre more readily and in greater quantity than the more solid, yet in passing through the rollers the thinner sample will be squeezed out in greater quantity and more readily than the thicker sample, and as a consequence weight for weight the sample with the greatest tenacity will give the stiffest cloth, and what the manufacturer has found out by experience is correct in theory, and Mr. Thompson and not my reasoning is fallacious.—I am, &c.,

GEORGE WHEWELL.

Exchange Chambers, Blackburn,
March 25, 1879.

TESTING OF GAS LIQUORS.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxviii., p. 193, there is a short article by Mr. T. H. Davis, "On the Testing of Gas Liquors." To those who have many of these liquors to test any contrivance that would tend to abridge the labour and at the same time afford reliable results would be hailed as a boon, and Mr. Davis is much to be commended for his efforts in that direction. The usual commercial valuation of gas liquors by degrees in Twaddle's hydrometer is so unsatisfactory that it is quite time it was superseded by some better method, and I think the test proposed by Mr. Davis gives at any rate a more reliable indication of the real strength of gas liquor than the method usually employed. I have not, however, found that this test is sufficiently accurate to supersede the usual distillation process, and I am not sure that Mr. Davis intends it should do so.

I have recently had five gas liquors placed in my hands for examination, and below I give the results of analysis by the method proposed by Mr. Davis (A), and also by the process of distillation (B)—

NH₃ per 100 parts of the Liquor.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 9, March 3, 1879.

Reply to M. Van Tieghem Concerning the Origin of the Amylobaeter.—A. Trécul.—The author points out that his words have been inaccurately quoted by M. Van Tieghem.

Emissive Power of Coloured Flames.—M. Gouy.—A mathematical paper, not susceptible of useful abstraction.

Absorption Spectra of Didymium and of Certain other Substances Extracted from Samarskite.—J. L. Soret.—The author has compared didymium chloride extracted by M. Marignac from samarskite with a sample from a different source. In the entire less refrangible part of the spectrum, from the red to the green, he finds no appreciable difference either in the colour or in the intensity of the rays, and the spectrum agrees very exactly with the figures in the work of M. Lecoq de Boisbaudran. In the blue and the indigo differences of intensity appear. Hence the author is led to the conclusion that the didymium from samarskite contains some foreign body. The same substance is present to a smaller extent in terbia, and less still in the didymium obtained from cerite.

Action of Ammonium Sulphocyanide upon Monochloric Aceton.—T. H. Norton and J. Tcherniak.—Instead of sulpho-cyan-aceton, as was expected, there was produced the sulphocyanide of a base, $C_4H_5N_2S$.

Amidated Acids Derived from the α -Butyric and Isovaleric Acids.—E. Du villier.—The acids described are the methyl-amido-isovaleric, the ethyl-amido- α -butyric, the ethyl-amido-isovaleric, the phenyl-amido- α -butyric, and the phenyl-amido-isovaleric.

Influence of Oxygen on Alcoholic Fermentation as Produced by Beer Yeast.—A. Béchamp.—Oxygen was found to exercise a favourable influence upon the production of alcohol. The quantity of acetic acid seems to depend much more on the temperature and on the nature of the yeast than on the oxygen. In short, the oxygen seems to act as a stimulus, under the influence of which the life of the yeast and the changes of its matter are more active. In a second set of experiments it was proved that the oxygen was actually absorbed.

Chemiker Zeitung.
No. 2, 1879.

Detection of Chromates and Free Chromic Acid.—To detect mono-chromate along with bichromate add to a few c.c. of the boiling solution a drop of a moderately concentrated solution of manganese sulphate. In presence of monochromate a blackish brown precipitate is formed. Bichromate in monochromate is detected by adding to a boiling solution of hyposulphite of soda an equal volume of a hot solution of the chromate in question. A brown precipitate or a distinct turbidity proves the presence of bichromate. The precipitate is chromic peroxide. Free chromic acid in a solution of bichromate is detected by adding solution of iodide of potassium and agitating with sulphide of carbon, which is coloured a deep purple by the liberated iodine.—*Zeitschrift Anal. Chem.*, 18, 78.

Determination of Sulphites and Hyposulphites.—If both salts are present together in solution, it is necessary to find the quantity of iodine which a part of the liquid requires if mixed with acetic acid; and the quantity of sulphate of baryta which an equal part of the solution yields after complete oxidation with bromine. Two equations are thus obtained with two unknown quantities. If a sulphate is also present its quantity is ascertained by adding to the liquid bicarbonate of soda, passing a current of carbonic acid through the liquid, heating after expulsion of the air, and after the addition of hydrochloric acid in excess concentrating to quarter its volume. The sulphurous acid being thus expelled the sulphur is filtered off, and the sulphuric acid in the filtrate is determined in the ordinary manner.—*Zeitschrift Anal. Chem.*, 18, 79.

Separation of Gold and Silver.—The metal is alloyed with 5 to 8 parts of zinc, for which the heat of a Bunsen burner is sufficient. The alloy is dissolved in nitric acid, when gold (with platinum and tin as stannic oxide if present) remains undissolved. To separate gold from platinum and tin they are dissolved in aqua regia, the

platinum metals are precipitated with ammonia, the free chlorine is expelled, and the liquid is mixed with excess of ammonio-ferrous sulphate, the excess of which is determined by titrating back with permanganate.—*Zeitschrift Anal. Chem.*, 18, 104.

Reactions of Bile Acids and their Detection in Urine.—A solution of the bile acids, if oxidised by the addition of ferric chloride, antimonie chloride, lead peroxide, barium peroxide with the addition of hydrochloric or sulphuric acid, especially if exposed to direct sunlight, passes through a variety of colours from yellow, red, vinous red, to blue and blue-violet. Similar colours are produced by the addition of stannous or antimonious chlorides along with sulphuric acid. Casali takes advantage of this play of colour for the detection of bile acids in urine. The urine is precipitated with sugar of lead and ammonia, the precipitate treated with ether and dilute hydrochloric acid, and the ethereal extract is drawn off and evaporated in three porcelain capsules at common temperatures. To the first residue are added barium peroxide and sulphuric acid; to the second tin crystals and sulphuric acid; and to the third antimonious chloride and sulphuric acid.—*Zeitschrift Anal. Chem.*, 18, 128.

Examination of Water for Bacteria.—Himly fills a flask, previously washed out first with hot concentrated sulphuric acid and then with the water in question, three-quarters full of the water, and adds a little solution of meat-extract, prepared by boiling extract for fifteen minutes in a large quantity of water. The flask is then stoppered and heated to $98^\circ F.$ on the sand-bath. Bacteria, if present, increase rapidly, occasioning a turbidity and a film on the surface of the water. The experiment requires about twenty-four hours. Distilled water similarly treated shows no turbidity.—*Zeitschrift Anal. Chem.*, 18, 117.

Action of Animal Charcoal on Salts.—Many salts, on filtration through animal charcoal, are held back more or less completely, or decomposed so that a part of the acid runs through, while the rest, in combination with the whole of the base, is retained by the charcoal.—*Zeitschrift Anal. Chem.*, 18, 97.

No. 3, 1879.

Dr. J. Volhard has been appointed Professor of Chemistry at the University of Erlangen, as successor to the late Gorup-Besanez.

A. Podewils proposes to convert faecal matters into poudrette by treatment with smoke, either of wood or coal.

Determination of Ferrous Oxide in Silicates.—Döller recommends the following process:—The finely pulverised mineral is covered with sulphuric acid and hydrofluoric acid in a platinum crucible set upon an iron plate. Over the plate is inverted a high beaker, whose edge fits into a groove made in the margin of the plate, and made air-tight by means of mercury or sand. From above, through a hole in the bottom of the beaker, a tube is passed to just over the crucible, and introduces a constant stream of carbonic acid. The whole apparatus is heated on the sand-bath, and the hydrofluoric acid escapes through the hole in the bottom of the beaker.—*Zeitschrift Anal. Chem.*, 18, 50.

No. 4, January 23, 1879.

A Contribution to the Fat-Industry.—Dr. B. Terne.—The author speaks of the application of the vapour of benzol in America for extracting oils and fats, not merely from wool and offal, but from bones, hoofs, &c. The fat of swine he remarks is apt to contract an objectionable colour. The chief difficulty is the removal of the characteristic odour of benzol. He has tried the action of benzol vapour upon tallow-greaves which had been previously submitted to hydraulic pressure of 10,000 to 12,000 lbs. per square inch, and obtained from 8 to 10 per cent of fat. The new Sanitary Office at Gera carefully examines all meat for *Trichina*.

Dr. Upmann, in consequence of some experiments upon

dogs, pronounces oxalic acid harmless. Dr. Pfeiffer, in reply, points out that the stomach and intestines of dogs generally contain considerable quantities of calcium phosphate by which the oxalic acid would be converted into calcium oxalate, an inoffensive salt.

According to the *Revue Industrielle* a metal has been extensively produced in France, which is a combination of iron and steel. The two metals are run separately into a mould divided into two parts by a thin plate of sheet iron, when the whole becomes welded together. The new metal is particularly adapted for armour-plating, anchors, and safes.

According to Fischer, in the *Metallarbeiter*, petroleum is adulterated with so-called solar oil, which occasions the dull yellow colour of the ordinary oil and its yellowish flame.

No. 5, January 30, 1879.

Dr. H. Geissler, of Bonn, died on the 26th ult. His establishment for the construction of physical apparatus will probably be carried on by Franz Müller, who has been for twenty-five years first his pupil and afterwards his assistant.

Lead, in dangerous quantities as an ingredient in the so-called tinning of sauce-pans, &c., has been detected by Dr. Brockhoff, of Magdeburg.

Dr. Wolff, inspector of factories for the Düsseldorf circle, has introduced a respirator for the use of men employed in white-lead works, lead smelting establishments, &c. The results are said to be satisfactory.

Test for Olive Oil.—Poutet proposes the following method:—Nitrate of mercury (doubtless mercurous) is prepared by dissolving 6 grms. mercury in 7.5 grms. nitric acid at 38° to 46° B. in the cold. Next 96 grms. of the oil in question are mixed with 8 grms. of the mercurous nitrate and shaken together every ten minutes for two hours. After being allowed to settle for twelve hours, if the oil was pure the elaidin thus formed is pale yellow and quite solid. In adulterated samples the elaidin is orange or dark red, and only partially or not at all solid. To detect the presence of the oil of sesame 2 parts of the sample are shaken up at a temperature of 20° to 25° with 1 part of pure hydrochloric acid at 22° B., in which 0.05 to 0.1 grm. of sugar has been previously dissolved. After standing for some time the oil separates from the acid, and if sesame is present assumes a rose colour. The more intense this colour the greater is the quantity of the impurity.

No. 6, February 6, 1879.

A. G. Moser, of Graben, in Thun, is said to have invented a remedy for the phylloxera, which completely eradicates it without injury to the vines.

T. Salzer has observed that sal-ammoniac and calcic hypochlorite react upon each other so violently as to give rise to an explosion.

Schneider, on preparing sodic hypochlorite by passing chlorine-gas into sodic bicarbonate, observed a rose colouration, which he traces to the presence of sodic ferrate.

No. 7, February 13, 1879.

A curious toxicological case is reported from Hamburg. The body of a man who died in 1867 was taken for examination. It was thought necessary to determine arsenic not merely in the corpse in question, but in the soil of the churchyard at different distances from the coffin, and also in the body of another man who had been subsequently buried in the same grave. This latter body was perfectly free from arsenic, which, however, was found in the first corpse in ample fatal quantity (0.24 grm.), whilst in the lid of the coffin and in the adjacent very minute quantities were traced. Hence the conclusion was fairly drawn that the man in question had been poisoned with arsenic, and that a portion of the poison had been gradu-

ally transferred from his body to the wood of the coffin and the adjacent soil.

Determination of Iron in Grain and other Food-Plants.—Eliosoff proposes the following method for the determination of iron in presence of phosphoric acid. The ash is evaporated to dryness with nitric acid, again taken up in dilute nitric acid, filtered, concentrated, precipitated with the molybdate of ammonia; the precipitate is digested upon the filter for some time with citric acid, the filtrate evaporated to dryness, the residue ignited, and re-dissolved in hydrochloric acid with the aid of heat, and the liquid separated by filtration from the liberated molybdic acid. In the filtrate the iron is determined as usual.—*Journ. de Pharm. et de Chimie*.

No. 8, February 20, 1879.

Dichromates.—Schulerud has prepared the dichromates of silver, thallium, and lithium, but has not succeeded in obtaining corresponding salts of lead, barium, and mercury. He concludes that univalent metals only yield dichromates, and argues hence to the univalence of lithium.

Detection of Salicylic Acid in Beer.—Blas recommends to drink the beer and in about three hours to test 20 c.c. of the urine with ferric chloride in the usual manner, as the reaction is about five times more delicate in urine than the original beer.

Extraction of Animal Pigments.—C. Méhu separates colouring matters from animal fluids by the addition of ammonium sulphate. In this manner he readily isolates the pigments of pathological urines, fecal matter, bile, serous liquids, &c.

Formation of Mannite in Beer.—The formation of mannite is always a mark of the want of cleanliness, and is particularly promoted by decaying wood. In such cases the sugar present enters not into the alcoholic but the mucic fermentation.

Moniteur Scientifique, Queneville. January, 1879.

Critical Examination of a Posthumous Work by Claude Bernard on Alcoholic Fermentation.—M. Pasteur.—This is merely the reproduction in full of a paper read before the Academy of Sciences, Nov. 25, 1878.

Causes of Death in Carbuncular and Septicæmic Affections.—M. Colin.—According to the author's views there is a death by the blood resulting from the inaptitude of this liquid to maintain the life of the cells and of the other anatomical elements. This type of death must be added to those characterised by Bichat, and is probably common to a great number of maladies, the carbuncular, the putrid, the typhic, and the pestilential.

Chemical Composition of Yeast.—M. Nægeli.—In this lengthy paper the author ascribes to bottom-yeast the following chemical composition:—

Cellulose and vegetable mucilage, forming the cellular membrane	37
Proteic matters—(a) In the state of albumen ..	36
(b) In state of phosphorous compounds ..	9
Peptones, precipitable by sugar of lead ..	2
Fatty matters	5
Ash	7
Extractive matters, &c.	4

100

Under the extractive matters are included small quantities of invertine, leucine, and grape-sugar; still smaller quantities of glycerin, succinic acid, cholesterin, guanin, xanthin, sarkin, probably of inosite and traces of alcohol.

Alkaloids of Veratrum.—A. Tobien.—Taken from the *American Journal of Pharmacy*, 1878, No. 3, p. 12

Optical Rotatory Power of Liquids and Dissolved Substances.—O. Hesse.—Translated from the *Annalen der Chemie*.

Action of High Temperatures upon Petroleum, Coal-tar, and Analogous Substances.—Alexandre Letny.—The author finds that the more elevated the temperature of the furnace which heats the still, the more the distillate is resinous and difficult to purify. This resinification becomes still more sensible when the flues are higher than the level of the petroleum in the still, in which case the vapours are decomposed by their contact with the heated sides. In the distillation of coal-tar and ozokerite, where it is necessary to avoid decomposition, the still-head and the pipe for the escape of vapours are placed as near as possible to the liquid; otherwise the paraffin would be decomposed. At augmented pressures and at a red heat petroleum is resolved into gaseous compounds.

On Ultramarine.—Dr. R. Hoffmann.—Taken from *Liebig's Annalen*.

Poisoning by Mushrooms.—J. A. Palmer.—Mushrooms may act as a poison in three different manners. They may act as an indigestible matter, which is the case with hard, coriaceous species, and may even occur with the edible mushroom when decomposing, as it gives off sulphuretted hydrogen in quantity sufficient to cause vomiting. Or, again, they may be glutinous or acrid. Many Boleti, otherwise innocent, are too gluey to serve as food. Lastly, mushrooms may contain a subtle alkaloid devoid of smell and taste, as happens in the group of the Amanitæ. This compound is known by the name of Amanitin, and to it the fatal cases of mushroom-poisoning are mostly due. No remedy has yet been found. No immediate effects are produced by this poison, but after eight to fifteen hours the patient experiences stupefaction, nausea, and diarrhoea, followed by delirium and death. Mushrooms containing this poison seem able to communicate it to wholesome species by contact, and it may also be absorbed through the skin. The author was on one occasion seized with alarming symptoms after carrying in this hand some Amanites wrapped in paper.

Resists in Calico-printing.—A. Schultz.—A purely technical paper, incapable of useful abstraction.

Aniline-black upon Wool and other Textiles.—M. Delory.—The author first mordants in 100 grms. each of potassic bichromate and oil of vitriol dissolved in 10 litres of water. The dye-bath he prepares by dissolving 30 grms. aniline hydrochlorate in 9 litres of water at 28°. In another vessel he dissolves 55 grms. potassic bichromate in 1 litre of boiling water, and adds to the hot solution 48 grms. sulphuric acid at 66° B. The solutions are then mixed together. In this liquid the tissues are worked for an hour without heat; the temperature is then raised quickly to 95° to 100°, and kept at that heat for 25 to 30 minutes. At the moment of applying the heat 10 to 12 grms. sulphate of copper are added, previously dissolved. The material is then taken out, washed very well, and taken through an alkaline bath of soap and soda, to which have been added 0.2 to 0.5 grm. aniline-violet per litre of water.

Historic Notes on the Discovery of Dyeing with Aniline-black.—In these notes M. Girardin, whilst admitting Mr. John Lightfoot's claim as the original discoverer of aniline-black, maintains that a M. Carl Stalare, of Lille, was the first who successfully used the new colour in dyeing under the name of "French black."

Poisonous Character of Salts of Copper and the Use of Copper Sulphate in Panification.—A collection of opinions on the innocence of the salts of copper.

February, 1879.

Industrial Society of Mulhouse.—The hydrosul-

phurous acid of Schützenberger and Lalande has been proposed for bleaching animal fibres in place of sulphurous acid. The white obtained is, however, not pure.

The insoluble ferricyanides are capable of oxidising indigo without the aid of an alkali.

Prof. Kopp communicates spectroscopic observations on eleven derivatives of resorcin, which he has just examined. The plates which accompany his memoir, and which represent the spectra of these different compounds, indicate the rays which he considers characteristic of methyl, bromine, iodine, &c., and which are the basis of his analytical method. M. Kopp, having as yet no data on the composition of these products, desires to obtain from the manufacturers who have furnished them the verification of his analyses before the publication of his memoir.

Colouring Matters Belonging to the Group of Azoic Bodies.—A. Kopp.—We have here an account of the preparation and properties of Bismarck-brown, of Magdala red, of azo-diphenyl blue, safranin, the chrysoidins, tropæolins, oranges, &c.

Glasses Melted with Alkali Alone.—Dr. P. Ebell.—Sodic and potassic sulphides, or sulphates in presence of reducing agents, on dissolving in glass at the melting-point impart to it a peculiar tint, varying from yellow to brown, and even to a deep red-brown if in sufficient quantity. In certain conditions the same colouration is produced by the introduction of free sulphur into glass, melted and kept at a high temperature. This colouration takes place only in glasses where there is sufficient available alkali to give rise to sulphides. To produce the colour there must be at least 1 equivalent of base to 2.5 of silica. The base may be lime or baryta, as well as potash or soda. Silicates in igneous flux are solvents for very various bodies, simple or compound. They dissolve free metals, such as gold, copper, silver, and lead; oxides, like chrome, alumina, stannic oxide, magnetic oxide of iron; also salts, such as sulphates, phosphates, aluminofluorides. These bodies are separated out on cooling either in a crystalline or an amorphous state, according to circumstances, and communicate different properties to the glass. The affinity of silica for bases measured by the carbonic acid displaced during fusion is not a constant magnitude, but depends on an action of mass. The quantity of carbonic acid expelled by a given weight of silica is so much the smaller the less alkaline carbonate there is in reaction.

Aniline and the Methylated Toluydins and the Colouring Matters thence Derived.—P. Monnet, F. Reverdin, and E. Noelling.—Already noticed.

MEETINGS FOR THE WEEK.

MONDAY, 31st.—Medical, 8.30.

TUESDAY, 1st.—Royal Institution, 3. "Animal Development," Prof. Schäfer.

— Zoological, 8.30.

— Society of Arts, 8. "Remarks upon an old Map of Africa Contained in Janson's Atlas, Published in Paris in 1612," and exhibited by R. Ward. "The Submarine Telegraph to South Africa," by J. Sivewright. (African Section.)

WEDNESDAY, 2nd.—Society of Arts, 8. "Some Causes of the Recent Depression in Trade," by B. Francis Cobb.

— Pharmaceutical, 8.

THURSDAY, 3rd.—Royal, 8.30.

— Royal Institution, 3. "Sound," Prof. Tyndall.

— Royal Society Club, 6.30.

— Chemical, 8. "On Terpin and Terpinol," Dr. Tilden. "On the Transformation of Aurin into Trimethyl-para-rosanilin," R. S. Dale and C. Schorlemmer. "On a Gold Nugget from South America," A. H. Wood. "On the Solution of Aluminium Hydrate by Ammonia and a Physical Isomeride of Alumina," G. C. F. Cross.

FRIDAY, 4th.—Royal Institution, 9. "Molecular Physics," by Mr. Crookes.

— Geologists' Association, 8.

SATURDAY, 5th.—Royal Institution, 3. "Etching," by Mr. Seymour Haden.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.

LIST OF OFFICERS AND COUNCIL.

President—E. FRANKLAND, Ph.D., D.C.L., F.R.S., &c.

VICE-PRESIDENTS.

F. A. Abel, C.B., F.R.S., William Odling, M.A., M.B.,
Alexander Crum Brown, M.D., F.B.F.
D. Mc, F.R.S.E., B. Angus Smith, Ph.D., F.R.S.
Robert Galloway, M.B.I.A., Augustus Voelcker, Ph.D., F.R.S.,
F.C.S.

Treasurer—C. R. Alder Wright, D.Sc., F.C.S.

ORDINARY MEMBERS OF COUNCIL.

John Atfield, Ph.D., F.C.S., David Howard, F.C.S.
James Bell, F.C.S., C. T. Kingszett, F.C.S.
Dugald Campbell, F.C.S., A. F. Marreco, F.C.S.
Michael Cartledge, F.C.S., F. A. Manning, F.C.S.
W. Crookes, F.R.S., V.P.C.S., E. J. Mills, D.Sc., F.R.S.
G. E. Davis, F.C.S., E. Nelson, F.C.S., F.R.A.S.
Warren de la Rue, D.C.L., F.R.S., John Pattinson, F.C.S.
William Dittmar, F.R.S.E., F.C.S., T. Redwood, Ph.D., F.C.S.
A. Dupre, Ph.D., F.R.S., F.C.S., J. Emerson Reynolds, M.D.,
R. J. Friswell, F.C.S., M.R.I.A., F.C.S.
J. H. Gladstone, Ph.D., F.R.S., Thomas Stevenson, M.D., F.C.S.
George Gore, L.L.D., F.R.S., M. E. Tatlock, F.R.S.E., F.C.S.
W. N. Bartley, F.R.S.E., F.C.S., B. V. Tison, F.C.S.
Douglas Herman, F.C.S., J. T. Way, F.C.S.

Secretary—C. E. Groves, F.C.S.

Offices—Somerset-house-terrace, S.W.

This Institute has been established to ensure that Consulting and Analytical Chemists are duly qualified for the proper discharge of the duties they undertake by a thorough study of Chemistry and allied branches of Science in their application to the Arts, Public Health, Agriculture, and Technical Industry.

NAMES OF FELLOWS.

Abel, F.A., C.B., F.R.S., F.C.S., Royal Arsenal, Woolwich, S.E.
Abney, Capt. W. W. F.R.S., F.C.S., 3, St. Alban's-road, Kensington, W.
Ackroyd, William, Kelso High School, Roxburghshire
Acworth, Joseph J., F.C.S., Oakville-house, Gravesend
Aitkin, Andrew P., D.Sc., Edinburgh University
Aldred, C.H., F.C.S., 3, Mining-lane, E.C.
Allen, Alfred H., F.C.S., 2, Collingdale-crescent, Sheffield
Allison, Henry T., Thornaby Iron Works, Stockton-on-Tees
Angell, Arthur, Ph.D., 4, Portland-terrace, Southampton
Angell, John, F.C.S., Grammar School, Manchester
Appleyard, Gilbert, C. W., Prestolee, near Manchester
Armstrong, H. E., Ph.D., F.R.S., F.C.S., London Institution, E.C.
Atkinson, Edmund, Ph.D., F.C.S., Portesbury-hill, Camberley
Atkinson, Robert William, Ph.D., F.C.S., University of Tokio, Japan
Atfield, Professor John, Ph.D., F.C.S., 17, Bloomsbury-square, W.C.
Bannister, Richard, F.C.S., Laboratory, Somerset-house, W.C.
Barfk, Frederick S., F.C.S., 100, Abbey-road, Kilburn, N.W.
Barrett, Edward Louis, B.Sc., F.C.S., 53, Springfield-road, N.W.
Bassett, Henry, F.C.S., 44, St. Paul's-road, N.W.
Baynes, James, jun., F.C.S., Kings-on-upon Hull
Bean, Charles Edward, F.C.S., Brooklin-house, Shepherd's-bush, W.
Beilby, George, Mid Calder, Scotland
Bell, J. Carter, F.C.S., Assoc. R.S.M., Kersal Clough, Higher
Broughton, Manchester
Bell, James, F.C.S., Laboratory, Somerset-house, W.C.
Bell, William Gomm, Assoc. R.S.M., 57, Duchesse-road, Birmingham
Blekerdike, William Edward, F.C.S., Surbiton-place, Blackburn
Blekerton, Professor A.W., Christchurch, New Zealand
Bischof, Professor Gustav, F.C.S., 4, Hart-street, Bloomsbury, W.C.
Bourne, Charles Edward, Messrs. Birdley and Co., The Brewery,
Burton-on-Trent
Bowdler, Arthur Clegg, 20, Wellington-street, Blackburn
Bowie, James John, F.C.S., Kingston, Jamaica
Brazil, Professor James Smith, F.C.S., University, Aberdeen
Brooks, John, British Alkali Works, Widnes, Lancaster
Brodie, Sir Benjamin C., F.R.S., F.C.S., Brackham Warren, Surrey
Brown, Professor A. Crum, M.D., D.Sc., F.C.S., 8, Belgrave-crescent,
Edinburgh
Brown, Adrian John, F.C.S., Burton-on-Trent
Brown, Edwin Ormond, F.C.S., Royal Arsenal, Woolwich, S.E.
Brown, James Campbell, D.Sc., F.C.S., Liverpool
Brown, Horace T., F.C.S., King Edward School, Birmingham
Buchanan, John Young, F.R.S.E., 10, Moray-place, Edinburgh
Bullock, J. Lloyd, F.C.S., 8, Hanover-street, W.C.
Burge, Charles E., Laboratory, Somerset-house, W.C.
Burghard, Charles Anthony, Ph.D., Owens' College, Manchester
Butterfield, John Cope, F.C.S., 106, Queen Victoria-street, E.C.
Caldwell, John, Addiwell, West Calder, N.B.
Cameron, Charles A., M.D., F.R.S.C.I., 15, Pembroke-road, Dublin.
Cameron, James, Laboratory, Somerset-house, W.C.
Cameron, John Macdonald, F.C.S., 7, Oxford-Villas, Glenhorne-road,
Hammer-smith
Cammack, John, 50, Pecker's-hill, Sutton, near St. Helen's
Campbell, Dugald, F.C.S., 7, Quality-court, Chancery-lane, E.C.
Carey, Eustace, Widnes, Lancashire
Cartledge, Michael, F.C.S., 180, New Bond-street, W.
Caswell, Charles Benjamin, F.C.S., 13, George-road, Birmingham
Coburn, Professor, F.C.S., Agricultural College, Cirencester
Clapham, Robert Calvert, F.C.S., Emsdon, near Newcastle-on-Tyne.
Clark, John, Ph.D., F.C.S., 138, Bath-street, Glasgow
Clandt, F., F.C.S., 6 and 7, Colman-street, E.C.
Cleave, Edward Lawrence, F.C.S., 280a, King's-road, S.W.
Clemenshaw, Edward, F.C.S., Greenhill, Sharncliffe
Cloud, Thomas Charles, Assoc. R.S.M., Walla-on, South Australia
Clowes, Frank, D.Sc., F.C.S., Newcastle-under-Lyme
Colman, Joseph James, F.C.S., 45, West Nile-street, Glasgow
Cooke, Samuel, M.A., Civil Engineering College, Poona, India
Coomber, Thomas, F.C.S., 80, Kingsdown-parade, Bristol
Corfield, Professor, M.A., M.B., F.C.S., 10, Bolton-row, Mayfair, W.
Cownley, Alfred John, F.C.S., 106, Fenchurch-street, E.C.
Cranston, George, Messrs. Storer and Sons, Sydney-street, Glasgow
Crookes, William, F.R.S., F.C.S., 20, Mornington-road, N.W.
Crowder, William, 2a, Evering-villas, Evering-road, Upper Clapton, E.
Dalziel, John Graham, United College, St. Andrew's, N.B.
Darby, Stephen, F.C.S., 140, Leadenhall-street
Darling, William Howarth, F.C.S., 126, Oxford-street, Manchester
Davies, Edward, F.C.S., Royal Institution, Liverpool
Davies, R. Higgins, F.C.S., 6, Bradmore-park-terrace, Goldhawk-
road, W.
Davis, G. E., F.C.S., Dagmar-villa, Heaton Chapel, near Stockport
Davis, Henry Wilson, Laboratory, Somerset-house, W.C.
Day, James John, 15, London-street, Derby
Deacon, Henry Wade, Appleton-house, Widnes
De Chaumont, Francis S.S.F., Army Medical School, Netley
De la Rue, Warren, D.C.L., F.R.S., 73, Portland-place, W.
Dent, William Y., F.C.S., Royal Arsenal, Woolwich, S.E.
Dewar, Professor James, F.R.S., Cambridge
Dittmar, Professor W., Anderson's College, Glasgow
Divers, Professor E., M.D., F.C.S., Yokohama, Japan
Dixon, William A., F.C.S., Chemical Laboratory, School of Arts,
Sydney
Dodd, Thomas Henry, F.C.S., Royal Arsenal, Woolwich, S.E.
Donkin, W. F., University Museum, Oxford
Dougall, Samuel S., Glenpark-villa, Busby
Downar, George Frederick, Worthington
Dreyfus, Charles, 7, Chapel-walks, Manchester
Dunoon, James, F.C.S., 71, Cromwell-road, S.W.
Dupre, Auguste, Ph.D., F.R.S., Westminster Hospital, S.W.
Early, William, Trinity College, Dublin
Elliott, Thomas, F.C.S., 55, Torriano-avenue, N.W.
Estcourt, Charles, F.C.S., St. James's-square, Manchester
Evershed, Frank, 8, Dalrymple-terrace, Glenarm-road, Capton, E.
Fairley, Thomas, F.R.S.E., F.C.S., 16, East-parade, Leeds
Farries, Thomas, F.C.S., 16, Coleman-street, E.C.
Fenton, Henry J. H., Christ's College, Cambridge
Ferguson, John, M.A., F.C.S., University, Glasgow
Field, Frederick, F.R.S., F.C.S., Hither-green-lodge, Lewisham, S.E.
Fletcher, Alfred, 5, Edge-lane, Liverpool
Ford, George, F.C.S., Royal Mint, Melbourne
Foster, William, B.A., F.C.S., Middlesex Hospital, W.
Francis, Ernest E. H., F.C.S., Port of Spain, Trinidad
Frankland, Professor E., D.C.L., F.R.S., Royal College of Chemistry,
South Kensington Museum, S.W.
Friswell, R. J., F.C.S., 10, Clapton-square, E.
Fuller, W. J., F.C.S., Curve-lodge, Gressaway-road, Redland, Bristol
Gale, Samuel, F.C.S., 338, Oxford Street
Galloway, Professor Robert, F.C.S., M.R.I.A., Royal College of
Science, St. Stephen's-green, Dublin
Gardner, John, F.C.S., 11, St. Paul's-crescent, Camden-square, N.
Garrick, Andrew R., Ph.D., St. Helena, Lancia-hire
Gatehouse, James Wright, 36, Broad-street, Bath
Gibb, John Henry, Ph.D., F.R.S., F.C.S., Harpenden, St. Alban's
Gibbs, Percy C., F.C.S., Assoc. R.S.M., Bismarck, Monmouthshire
Gladstone, J. H., Ph.D., F.R.S., F.C.S., 17, Fensbridge-square, Hyde-
park, W.
Glover, G. T., F.C.S., 30, Donegall-place, Belfast
Gordon, Joseph Gordon, F.C.S., 20, King-street, S.W.
Gore, George, L.L.D., F.R.S., Islington-row, Edgbaston, Birmingham
Graham, A. McDonald, F.C.S., 5, Fastfield, the Links, Leith
Graham, Charles, D.Sc., F.C.S., University College, W.
Greenaway, A. J., F.C.S., 11, Pemberton-gardens, Upper Holloway, N.
Greenway, Thomas, The Sheffield Smelting Company, Sheffield
Gregory, Henry Richard, 7, Quality-court, Chancery-lane, E.C.
Greville, Henry Leicester, F.C.S., Benunc-house, Stroud-green-road
Gries, Peter, Ph.D., F.R.S., F.C.S., Burton-on-Trent

Fellows and Associates are requested to give notice of Change of Address to the Secretary.

The Prestolee Alkali Works, Farnworth, near Bolton, Lancashire, fitted with costly Plant, Machinery, and Apparatus for the Manufacture of Soda-ash, Bleaching-powder and Liquor, and Sulphuric Acid, in complete working order, with possession.—Preliminary.

MESSRS. FULLER, HORSEY, SONS,

and CO. are instructed to SELL by AUCTION, at the Palatine Hotel, Manchester, on Thursday, April 17, at 3 o'clock precisely, in one lot, unless an acceptable offer be previously made by private contract, the PRESTOLEE ALKALI WORKS, a freehold property, having a superficial area of 95,741 square yards of land, subject to chief rents amounting to £407 13s. 9d. per annum, with the buildings, plant, machinery, and apparatus erected thereon, capable of manufacturing monthly a product exceeding in the aggregate 2000 tons of soda-ash, bleaching-powder and liquor (by Weldon's patent process), and sulphuric acid, also caustic soda and muriatic acid. The amount expended in the construction of these works has been very large. A valuation was made with great care in 1874 by Messrs. Holmes and Son, the well-known valuers, of Manchester; their estimate then amounted to £99,000, and since that time a sum exceeding £10,000 has been expended. The whole of the works and plant have been well kept, and are conveniently arranged for working. The Bury, Bolton, and Manchester Canal, which forms one boundary of the property, affords facility for economical water carriage, and the Lancashire and Yorkshire Railway is within a very short distance. There is a plentiful supply of water for all manufacturing purposes, free of cost, from the river Croal, and coals are raised from pits in the immediate neighbourhood. Pyrites, salt, lime, and limestone are all brought by boats direct to the wharf on the canal. The works may be economically worked with a small capital, as arrangements may be made with the vendors for a very considerable portion of the purchase money to remain upon mortgage. Large profits have been realised in the past, and the high reputation of the Prestolee manufactures in the market will ensure to an energetic man, even at the existing low prices, an ample return for his capital invested and possession of works not surpassed for completeness or compactness by any in the kingdom. May be viewed till the sale. Printed particulars are in course of preparation, and may shortly be had at the Works; at the Palatine and Queens Hotels, Manchester; of Messrs. Wakeman and Bleack, Solicitors, Warminster; of Messrs. Adleshaw and Warburton, Solicitors, Norfolk Street, Manchester; and of Messrs. Fuller, Horsey, Sons, and Co., 11, Billiter Square, London, who are empowered to treat for the disposal by private contract.

Prestolee Alkali Works, Farnworth, near Manchester and Bolton.—Useful Horses, rolling stock, loose effects, and remaining stock-in-trade.

MESSRS. FULLER, HORSEY, SONS,

and CO. are instructed to SELL by AUCTION, on the PREMISES, Farnworth, near Manchester, on THURSDAY, April 17, at twelve precisely, the ROLLING STOCK, loose materials, and stock-in-trade, including 16 powerful cart horses, four wrought-iron tank trolleys, nine lorries, 11 spring tip and float carts, harness, two cast-iron caustic pots, cast-iron decomposing pot, double-flue Lancashire boiler 7 ft. diameter, 19 ft. 6 long, about 30 tons useful wrought- and cast-iron material, 3 tons lead, brass cocks and tape slate slabs, York stone foundations, new wire netting, useful ash timber spokes and felloes, earthenware aqua fortis jars and packing boxes; also 25 tons soda-ash, 72 carboys rectified oil of vitriol, 300 empty carboys, and numerous other effects.—May be viewed the day preceding the sale, and catalogues had on the premises, of Messrs. Wakeman and Bleack, Solicitors, Warminster; of Messrs. Adleshaw and Warburton, Solicitors, Norfolk Street, Manchester; and of Messrs. Fuller, Horsey, Sons, and Co., 11, Billiter Square London, E.C., or will be forwarded on application.

MR. EDWARD T. BARRETT,
ACCOUNTANT AND FINANCIAL AGENT,
Gives information without charge to Investors in Stocks and Shares, and conducts the Sale of

ALL CLASSES OF SECURITIES

on reasonable terms.
Mortgages are also effected for inventors and others at fair rates
Patents secured for Inventions relating to Electricity and Mining Chemistry.

Advice and instruction given in all matters of Account.
38 GREAT ST. HELEN'S, E.C.

WILLIAM AND WILLIAM T. FIELD,
MANUFACTURERS of the Celebrated
STAFFORDSHIRE BLUE BRICKS, specially adapted for
Chemical Plant, i.e., Acid Towers, &c. Also all other kinds of Best
Staffordshire Blue Bricks, Pavings, Plyths, Splays, Copings, &c.
&c. Prices and samples on Application.

TESTIMONIAL.

"We have used the Blue Staffordshire Brick for Sulphuric Acid Towers, &c., manufactured by Messrs. Field, for the last fifteen years, during which time they have given great satisfaction. We recommend them to the Chemical Trade, believing there is nothing better in the market."—(Signed) WILLIAM HUNT and SONS, Lea Brook Alkali Works, near Wednesbury, Staffordshire, February, 1878.

TOLL END BRICKWORKS,
TIPTON, STAFFORDSHIRE.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1010.

BLUE FLAME FROM COMMON SALT.

By A. PERCY SMITH, F.C.S., F.I.C.

SOME time ago the question was raised in *Nature* concerning the origin of the blue flame produced when common salt is thrown into a hot fire.

Among the suggestions that were advanced, no one offered the only explanation that is at all feasible, viz., that it is due simply to hydrochloric acid.

The blue flame is not produced by sodium chloride only, but by other chlorides as well. Those I have tried are— BaCl_2 , SrCl_2 , KCl , AmCl , Hg_2Cl_2 , and HCl , the last both in solution and as gas. It would be waste of time and space to enumerate all the experiments I have made on this subject; many of them were for the purpose of proving that neither carbon nor sulphur had any share in the reaction.

do not pretend to any high degree of accuracy in my delineations of the lines; besides the different conditions under which the two were compared might account for considerable variations.

For the HCl I used a coil (capable of giving a 2" spark) with a Leyden jar, and worked by 6 Smées. The carbon points were $\frac{1}{8}$ -inch apart. The spark was tried both focussed and unfocussed on the slit of a 2-prism spectro-scope.

When comparing the two spectra side by side it was difficult in some cases to be sure of coincidence, because the flame from the Hg_2Cl_2 would flash out brilliantly for a moment and quite overpower the more feeble lines of the HCl ; it would then disappear entirely, and more chloride would have to be placed on the gauze.

I have no doubt in my own mind that HCl is the cause of the blue flame. I have proved that Cl is a necessary constituent, and I have not been able to get it in the absence of hydrogen (the spectrum of pure Cl is very different); and, besides, the red H line is present in both cases, and probably the other two as well. I do not think that the presence of aqueous vapour is sufficient to account for the red line.

I subjoin the spectra as I mapped them; but it must be borne in mind that I do not vouch that they are without error. I intend to photograph them when I have sufficient

One of my methods of obtaining the flame was to burn pure hydrogen from a glass jet, and allow a mingled stream of HCl and NH_3 from two other jets to pass into it. The best source, however, is calomel, heated on wire gauze by a Bunsen burner; the next best AmCl . The spectrum of the "chloride" flame is characterised by a series of double bands in the green, blue, and violet, the least re-frangible of each pair being the broadest. The four pairs in the violet are especially prominent. There are two red bands or lines and one orange. The least re-frangible red line occupies the place of the hydrogen line C. A spark between carbon points in a bottle of HCl gas yields a spectrum similar in appearance to that obtained from a chloride, but I was unable to see any violet bands, only a faint continuous spectrum. I was able to ascertain that the red lines coincided exactly, but I cannot affirm with the same positiveness that all the green lines and bands coincide. Some undoubtedly do; but the spectrum of the HCl was so faint and the spectrum of the chloride so transient that measurements were very difficult, and I

leisure, and I hope the results will be more definite. I may be able to find violet lines in the spectrum of HCl .

Rugby, March 15, 1879.

ON SUPERSATURATED SOLUTIONS.

By J. G. GRENFELL, F.G.S.

I STAND corrected by Prof. Tomlinson thus far, that his paper was *received* by the Royal Society in September, 1877, and not *read*, as I previously stated.

As regards my description of his paper as one intended to upset my theories and uphold his own, I cannot see that Prof. Tomlinson has to find fault with. In using those words it never occurred to me that any one would emphasise the pronouns *my* and *his*, and suppose that I intended to imply he had any personal feeling in the matter. No one who knows Prof. Tomlinson would sup-

pose that for a moment. He battles stoutly against what he believes to be error, and I found no fault with that. What I did complain of was the passage which I quoted in my letter of January 10th. Every one to whom I have shown his paper agrees that the words as they stand distinctly imply that I denied the fact of the lecture-table experiment with Glauber's salt.

Prof. Tomlinson denies that he anywhere implied this. I am glad to accept this as an expression of his intention, but I cannot admit it as a fair description of the words he used. I have laid stress on this only because the line taken by Prof. Tomlinson in that paper is that I am at variance with all my predecessors, a point to which I shall have to recur, and that after repeating some of my experiments his results were contradictory of mine.

Prof. Tomlinson also protests against my making him out to be ignorant of the very simple conditions necessary for the success of the experiments with drops on a glass plate. The case stands thus:—In his paper he gives a general statement, applicable apparently to all supersaturated solutions, that when a point was drawn through a drop so as to deform it, crystallisation sets in. This is in dry weather. I have drawn a point through hundreds of drops of the strongest solutions of sodium sulphate, carbonate, and acetate, on recently washed plates, in all kinds of weather, without causing crystallisation; I have just tried this with sixty drops of a strong solution of the acetate, and it was inactive in every case. I have deformed drops of ammonia alum, which had begun to deposit the modified salt, on a plate over calcium chloride, and repeated this with sodium carbonate and acetate over sulphuric acid, and the scratching had no effect whatever when the plates were put back over the chloride and acid.

I explain this difference in our results by supposing that Prof. Tomlinson did not take sufficient care in cleaning his plates. There is nothing which need hurt him in the supposition, because it is only the experience given by a long series of experiments with plates which has taught me what precautions have to be taken. It is in the same spirit that Prof. Tomlinson quietly dismisses what he calls my minute criticism, as throwing no light on the circumstances under which these solutions crystallise. Experience has taught me that it is only by the minutest possible criticism of each case that we can hope to arrive at the explanation of these very difficult phenomena. I recognise at present three well-established ways in which a supersaturated solution may be made to give the normal salt. The first is by introducing a crystal of the same salt, or of an isomorphous one of similar constitution as Mr. Thomson has recently shown. The second is by the mechanical action of absorbent substances, when not at once saturated by the solution. The third is by cold. Until it is proved that these three do not apply to the case in point, I refuse to look for any other cause.

Now the first two of these causes exhibit the most extraordinary delicacy in their mode of operation. Mr. Liversidge agrees with me in explaining the action of the minute aerial nuclei by their absorptive power. Hence if Prof. Tomlinson's plates had minute organic particles on them in dry weather these would cause the crystallisation of his drops when, by deforming them, he brought the solution in contact with these nuclei. He notices himself that if the tail formed sprang back crystallisation did not ensue, and I have always found that plates exposed to air are much more likely to be active than plates recently washed or dried under cover.

The extraordinary delicacy of the second cause has been proved in the course of my own experiments, of which I will give a few. A large glass plate, on which drops of sodium acetate had been made to crystallise, was carefully washed in cold water, and then dried and exposed to the air. A great many drops of a strong solution of the acetate were then put on it, and all remained liquid; but I found that scratching with a pin inside the drops made every one of them crystallise instantly, although the

every experiment. I naturally thought at first it was a case of scratching causing crystallisation; but I had so often scratched the acetate without effect that I was very loth to believe it. I then washed the plate with boiling water, and then scratching had no effect whatever on many drops of the same solution. The acetate has a very remarkable power of adhesion, and was still present in the depressions of the plate covered by weaker solution, but was unable to determine the crystallisation of the drops until scratching brought it in contact with the strong solution.

A few days ago I took an apparently clean plate, washed it carefully in cold water, put drops of the acetate on it, and then put it over calcium chloride. In an hour or two the modified salt was forming on the drops by evaporation; then scratching with a pin made every drop crystallise. This looked very like a confirmation of Prof. Tomlinson's results. But on washing the plate in hot water, and repeating the experiment, scratching had no effect whatever, and when put back over sulphuric acid for two days only the modified salt was formed. Probably the plate had previously been used for the acetate; possibly, in the first case, nuclei had not been thoroughly removed, but the acetate is so little sensible of absorbents that this latter supposition is not at all probable.

Again, a pin had been frequently used for making the acetate crystallise, and often heated red hot; it was rubbed through the fingers and then left $3\frac{1}{2}$ hours in cold water; it was then immediately active, not on quietly putting it into a drop, but on scratching; whilst boiling water cleaned it at once.

It is evident that these facts must be taken into consideration if we do not wish to have results ascribed to all sorts of wrong causes. Another fact of the same kind is not without interest. Dr. De Coppet has described two isomeric modifications of anhydrous sodium sulphate (*Comptes Rendus*, lxxviii., p. 194), one formed by dehydration above 33, the other formed at lower temperatures. This latter kind, he says, determines the crystallisation of a solution of the salt as the normal, whilst the former does not. M. Gernez suggested that this was because at a low temperature the sulphate did not perfectly effloresce. I tested the point by rubbing some of the salt very fine in an agate mortar and then exposing it for weeks over calcium chloride. I then took a plate with a large number of drops of the sulphate and tested various portions by taking up a little with a pin and introducing it into a drop. I found that all the thicker parts were immediately active, but that here and there a small very thin patch was inactive, and the anhydrous could be seen to dissolve in the drop. Hence it is clear that M. Gernez's explanation is correct. This method of testing is one of extreme delicacy for the presence of salts which form supersaturated solutions.

Another illustration of the necessity of minute investigation is the following:—

Some years ago I showed that scratching a solution of sodium sulphate in about six parts of sulphuric acid causes crystallisation. I attributed it at the time to vibration upsetting the state of unstable equilibrium. My colleague, Dr. Tilden, found that the same thing happened when drops of potash alum were scratched; and at a lecture in Bristol he gave it as another instance of vibration. But I have since found that by taking extreme care in cleaning the plate and using one recently washed scratching is by no means always active. I attribute this case also to the presence of absorbents on the plate. I am also strongly inclined to believe that the effect of scratching the acid solution mentioned above is due to the same cause. Rubbing drops of this with a hard, compact wood has no effect, but it always crystallises by absorption on the end of a match simply dipped in the drop and laid aside. Little shavings of a match kept floating on a drop act in the same way, but very often not if they are pushed into the drops. It is easy to see how the solution would gradually act on the organic particles

in the depressions of the plate, and then scratching brings the crystals which are forming into contact with the stronger solution. I did once find a plate inactive when scratched, but I have never been able to reproduce the conditions, although I have tried several ways of cleaning the plates. It must also be carefully borne in mind with regard to these experiments with drops that the sensitiveness to absorbents depends on the strength of the solution, and also on the temperature.

In hot weather I found that a rather weak supersaturated solution of sodium sulphate was absorbed by filter-paper without giving the normal salt even when dry, as the filter-paper was cut up and introduced into drops without producing any effect. This can never be done, as far as my own experiments go, with strong solutions of that salt. Absorbents also, such as filter-paper, have no effect whatever on sodium acetate except in the very strongest solutions.

It appears, then, that in discussing the question why these solutions crystallise or do not crystallise in a given case, we have to take account of the strength of the solution, of the temperature, of the possible presence of the salt when least expected, of the freedom of the plate from dry absorbent bodies derived from the air or elsewhere, and of a specific sensitiveness to absorbents peculiar to such kind of salt. This necessitates minute criticism, and with all deference to Prof. Tomlinson's opinion, I maintain that one or other of these considerations has frequently led me to a simple explanation of results which are otherwise most puzzling. The action of oil on these solutions is a very simple one according to Prof. Tomlinson; when a film adheres to the solution the normal salt separates. But I find that the phenomena are much more complicated.

When solution of sodium carbonate is dropped into oil, or is rubbed with oil, a salt separates at once, which is not the normal salt, as it can be introduced into drops without causing crystallisation. I have also seen a very pretty thin flexible opalescent film form at once round the sides of a drop of ammonia alum on oil. As I write, three drops of a strong solution of potash alum are lying unaltered in castor oil; yet I have often found oil rubbed on a plate powerfully unclear to this solution. On sodium acetate I have never found oil have any effect, nor on the sulphate when proper precautions are taken. It is quite possible that the oil acts by catching up absorbent particles of dust, but the subject needs investigation.

I have omitted to notice a property possessed by these solutions which may easily prove a source of error. When small *well-shaped* crystals of the salt are forming in a solution or in a drop they may continue to grow for hours very slowly; but if one of these is broken the drop crystallises with a flash. It may, as far as my experiments go, be taken as a general law that broken crystals have much more effect in producing crystallisation than perfectly-shaped ones. The crystal seems to have the power of growing with much greater rapidity along one of its axes than along the others. It is this property which makes a strong solution crystallise in fibres, while a weak solution gives well-shaped crystals. In the former case the growth of the more powerful axis does not sufficiently diminish the strength of the solution in front of it to check the rate of growth; in the latter case the crystal is surrounded constantly by impoverished solution, which gives time to the lateral forces to develop themselves.

Hence a drop on a plate may really be crystallising in the depressions of the plate, but very slowly, and the experimenter will find that scratching causes crystallisation at once, or that the drop will crystallise spontaneously after a certain time.

I find that a pin which has been heated red-hot often, and is used for making the acetate crystallise, and is then left in water for an hour or two, makes drops of the acetate crystallise very slowly in large well-formed crystals, whilst scratching makes it crystallise at once in fibres all over. This subject of the relation of crystalline form to

the conditions under which the crystals were formed is interesting to geologists as well as chemists.

The last point I have to notice is one which Prof. Tomlinson insists upon in his paper, and in his note to you; it is that I am at variance with all my predecessors. He says that Loewel, Violette, and Liversidge expressly state that porous bodies, bodies greedy of water and capable of hydration, are incapable of determining the solidification of these solutions.

He has forgotten, as I did at the time of making my experiments on absorption, that Mr. Liversidge, in his last paper in August, 1870, enunciated the absorption theory in these words:—

"(1) It is not impossible that nuclei consist of microscopic organisms which act by abstracting water, the action being set up at a point from which it is propagated throughout the mass; (2) that they are rendered inactive by heat because it entirely destroys them; (3) that their action is arrested by previous saturation in water, because they then can no longer abstract water from a saline solution."

He had only made a couple of experiments with lycopodium, which he found to be active when dry and inactive when wet, but he expressed a hope to have shortly the results of other experiments. Unfortunately, he never resumed the subject. My own experiments on absorption were begun five years later, when I had forgotten all about Mr. Liversidge's suggestion, and when I was working at a different part of the subject. They entirely confirm Mr. Liversidge's views as to the action of nuclei; they show that the action of absorbents in considerable quantity resembles that of nuclei, but with two important modifications, which determine the conditions under which the absorbents act—namely, that they are inactive if saturated at once by the solution, and that very rapid absorption often prevents crystallisation. It is only in virtue of this extension and modification that I can lay any claim to the theory as my own, and my results are in perfect harmony with those of the only person who, with the exception of Prof. Tomlinson and M. Gernez, has really worked at this subject in recent years. It is true that Loewel, Violette, and Liversidge state that phosphoric anhydride and other dehydrating substances have no effect; but I have shown that when these substances are introduced into a considerable bulk of the solution, so as to be saturated at once, crystallisation does not ensue.

ON INDIGO-BLUE

FROM

POLYGONUM TINCTORIUM AND OTHER PLANTS.

By EDWARD SCHUNCK, Ph.D., F.R.S.

(Concluded from p. 130).

Blotia Tankervillea.

THE occurrence of a blue colouring-matter in this and other plants belonging to the Orchidaceæ, such as *Calanthe veratrifolia*, was first noticed by Clamor-Marquart* and by the late Dr. Crace Calvert†. The attention of these observers was directed to these plants by seeing the blue colouration appearing in the white petals of the flowers on their beginning to fade; and they found the blue colour to be due to indigo. In accordance with the views then prevailing, they assumed the pre-existence of the colouring-matter, either as indigo-blue or as its hydride, in the tissues of these plants. It is easy to see, however, on reading the accounts of their experiments that the colouring-matter was really formed during the processes

* Buchner, Repertorium f. die Pharmacie, B. lvi. f. i.

† Journal de Pharmacie, t. vi, p. 193.

employed for its extraction; and it seemed to me, therefore, highly probable that the plant would be found to contain some glucoside similar to indican.

Bletia Tankervillea is not difficult to procure, being frequently grown for the sake of its handsome brown and white flowers and its general beauty. The leaves of the plant having been cut in pieces and ground with water between two stones to a pulp, which is strained through calico, yield a green muddy liquid which, heated to near the boiling-point, gives a thick green coagulum. The liquid filtered from this coagulum is clear, of a deep yellow colour, with a slight acid reaction and an acrid taste. When this liquid is mixed with sulphuric or hydrochloric acid and left to stand, it deposits dark-coloured flocks consisting of indigo-blue mixed with a substance which imparts a purple colour to boiling alcohol, probable indirubine. The presence of glucose may be detected in the filtrate by the usual test, while the same test applied before the addition of acid shows no indication of its presence. It may hence be inferred that the liquid contains in solution a glucoside similar to, if not identical with, indican. It undergoes, like indican, a complete change when submitted to the action of alkalis; for if its watery solution be mixed with caustic alkali and boiled, then with an excess of sulphuric acid and again boiled, it deposits brown flakes, which are found to contain but little indigo-blue, while in the filtrate only a trace of glucose can be detected. The same change takes place gradually when the watery solution is left to stand for several days at the ordinary temperature.

The gradual formation of indigo-blue in the leaves of *Bletia Tankervillea* may be easily traced in the same way as with those of *Polygonum tinctorium*, by placing the lower ends, immediately after cutting, in dilute hydrochloric acid and leaving them freely exposed for a few days. The acid, as it ascends, causes a dark discolouration; and the part discoloured, after immersion in boiling alcohol to remove the chlorophyll, appears blue.

Indigofera tinctoria.

It would be a matter of some interest to ascertain in what state the colouring-matter exists in this the most important of all the plants yielding indigo. From what I have said, however, it will be apparent that, in order to arrive at a certain conclusion, it would be necessary to work with fresh leaves; for if they contain a glucoside resembling indican, this would in a very short time undergo complete decomposition. I obtained some seeds of *Indigofera tinctoria* from Messrs. Vilmorin, Andrieux, and Co., and treated them in accordance with the directions they kindly gave me. The seeds germinated, and the young plants lived for some time in a hothouse; but unfortunately, they attained no great size, and soon decayed and died, so that I was unable to obtain a quantity of leaves sufficient for examination.

Mr. P. Michéa, an intelligent indigo-planter, with whom I have been in correspondence, gives me, however, some interesting information relating to this part of the subject. Mr. Michéa writes to me as follows:—"It was my finding in the *Indigofera* of India (in the wild plant which grows at many places in the three Presidencies as well as in the cultivated species of Bengal, the North West, and Madras) a glucoside substance perfectly similar to the indican of the *Isatis tinctoria* in all its properties, which made me declare that the colouring-matter of the Indian *Indigofera* was due to indican."

The experiments just described lead to the conclusion that in all the indigo-yielding plants hitherto examined, the colouring-matter is derived from a glucoside which splits up with great ease into indigo-blue and glucose, and that this glucoside is probably, in all cases, the same, and identical with, the indican of *Isatis tinctoria*.

Various other plants have been supposed to yield indigo-blue. Of these I have examined the following:—

Galega officinalis.

Hedysarum Onobrychis (Sainfoin).

Polygonum Fagopyrum (Buckwheat).

Polygonum Persicaria.

Rhinanthus Crista-galli.

Sophora japonica.

Spilanthes oleracea.

The leaves of these plants, when treated in the manner above described, yielded no trace of any substance resembling indican, and showed no indications of containing any blue colouring-matter like indigo.

CRYSTALLISATION OF PHOSPHORUS.

By GEORGE WHEWELL, F.I.C., F.C.S.

IN 1872, while experimenting on the action of phosphorus on nitrogen gas in sealed tubes, after melting the phosphorus and spreading it over the sides of the tube and allowing the tube to stand for several weeks, I noticed small colourless crystals begin to form. In 1874 I noticed abstracts of two papers in the *Chemical Society's Journal* (2nd series, vol. xii., p. 86g) by J. L. Smith and W. L. Herman, on the formation of crystals of phosphorus *in vacuo*. I wrote a note to the *CHEMICAL NEWS* (vol. xxx., p. 168). I did not claim priority or originality, or try in any way to detract from the merit of Messrs. Smith and Herman's papers. In Mr. Herman's letter (vol. xxx., p. 194) he tried to throw ridicule on my note, and even hinted his opinion that I had not made any crystals at all. I prepared a test-tube and sent it to Dr. Burghardt, of the Owens College, Manchester, and I append his letter, as requested by Mr. G. E. Davis (vol. xxxix., p. 115).

"The Owens College, Manchester,
"March 2, 1875.

"DEAR SIR,

"I thoroughly investigated the matter you requested me to enquire into, immediately after receiving the tube containing the phosphorus crystals. Of course you are aware that crystals of phosphorus have been obtained in other ways long ago, and it was conclusively proved that they belonged to the regular system of crystallography. The crystals in the test-tube you kindly sent me were undoubted phosphorus crystals, exhibiting the two characteristic forms observed on crystals prepared by dissolving phosphorus in rock-oil when hot and cooling, and the methods published long ago. The forms I observed were the regular octahedron and the rhombic dodecahedron, with rather rounded edges, the interfacial angles not being sufficiently well defined to allow of accurate measurements being made. There can, however, be no doubt about their being the two forms mentioned above. On opening the tube for a few seconds fumes of phosphorus came out, and the tube on being closed again, and left alone for a few days, was thickly coated with amorphous phosphorus and the crystals had vanished. . . .—Believe me, &c.,

"C. H. BURGHARDT."

"The Owens College, Manchester,
"March 18, 1879.

"DEAR SIR,

"The forms observed on the crystals were the octahedron and the rhombic dodecahedron, the former predominating; the crystals did not exhibit any sharply-defined edges or angles, consequently goniometrical measurements were not possible. The crystals were perfectly transparent. . . .—With kind regards, &c.,

"C. H. BURGHARDT."

My friend, Mr. W. H. Wood, now of the Yorkshire College, wrote me, in November, 1874:—

"I have tried your method of producing phosphorus crystals and was successful, as I could easily distinguish crystals when I examined the tube two or three days after. . . ."

Very few chemists have made crystals of phosphorus, and the only thing I claim in the above method is a very

ready means of preparing crystals of phosphorus suitable for lectures or showing it to a class when treating of phosphorus and its compounds. The method places phosphorus crystals in the hands of anyone who cares to spend ten or fifteen minutes in preparing them. I am sorry I have not studied the subject further, being fresh from College at the time, and the note being my first attempt at writing I was somewhat cowed. I came to the conclusion that Mr. Herman thought he had a vested right in crystals of phosphorus.

I have found the following the best plan for producing the crystals:—Take a piece of glass tubing and seal one end (or a test-tube); place at the bottom of the tube a piece of phosphorus about the size of two peas; draw out the other end; then heat the tube, commencing about one inch or so above the phosphorus, so as to drive out as much air as possible; then seal the open end (or cork the test-tube and make it air-tight). Melt the phosphorus, and spread it as thinly and evenly over the sides of the tube as possible. Allow to stand for a week or two, or place into a freezing mixture, when crystals will form in a few days.

END-ON ILLUMINATION IN PRIVATE SPECTROSCOPY, AND ITS APPLICATIONS TO BOTH BLOWPIPE FLAMES AND ELECTRIC ILLUMINED GAS-VACUUM TUBES.*

By PIAZZI SMYTH,
Astronomer Royal for Scotland, and past President of R.S.S. Arts.

PART I.

Defects of Former Methods, and New Conditions to be Fulfilled.

As there is nothing in the shape of splendid optical projection of grand phenomena on a large screen connected with the present paper, and as it refers merely to a practical difficulty, as met with by a private worker in a small way, in connection, too, with only a very limited branch of the general subject of spectroscopy,—some apology may be necessary for bringing so apparently trifling a matter before any public meeting. Especially, too, is such an explanation required before this long-established Society, which has had all the finer bearings of the higher spectrum analysis expounded to its members so often and so eloquently by Dr. Stevenson Macadam, and illustrated so glowingly by Mr. Hart's electric lamp, years and years ago, that not a few persons may have almost identified the subject itself, or anything about spectroscopy, with that particular and assuredly most magnificent method of demonstration. My excuse, therefore, can only consist in trying to make out, and perchance bringing home, though by mere words only, to the inner conscience of some real workers (of whom there must be many here) the exact manner of occurrence of a serious, albeit small, case of positive scientific difficulty; or in showing how a very lion of a trouble was one day found to be seated right across the special path of progress and research which I was desirous of pursuing. But how, after due interrogation as to wherefore he came to be there, the said lion was presently induced to get up, make himself scarce, and not exhibit his threatening front, to me at least, in that locality again.

If, therefore, the Society will be graciously content with such a modest bill of quiet fare as that, I will at all events endeavour to make the nature of the case very clear. With this purpose, therefore, I now commence with what is generally admitted by all the world as being foundational in spectroscopy; while it is also the necessary beginning of our subject for this evening, viz.:—

In every kind of spectroscopic observation, high or low, of fire or flame, public or private, *brilliantness* in the light operated on—so far as it can be fairly commanded—is the soul of success. In private researches, too, more particularly, where we merely look into the eye-piece of a small optic tube for our own sole and, for the time, solitary satisfaction, the mere quantity of shining matter being examined is of no sort of consequence; for we view of it at a time only as much as fills a little slit in a metal plate about $\frac{1}{16}$ inch high and $\frac{1}{32}$ inch broad. A minute, or no more than microscopic sized, particle is therefore enough, in that way; but *brilliant*, and even three times brilliant, the intrinsic light of that little particle must be, or you will be condemned to employ only the least disperse of prisms wherewith to form its spectrum; and therein, from the extreme red, all the way through the orange, yellow, green, blue, and right up to the ultimate violet and lavender grey of the spectral field, you will fail (if your spectrum is of the all important "discontinuous" order) to see anything but merely a few faint, hazy-edged, unsatisfactory bands. In place it might, or should, have been of multitudes of vivid lines, capable of almost unlimited nicety of micrometric measurement, and as firmly fixed in their several and respective spectrum places, as are the very stars of heaven in their almost eternal positions.

"Then, of course," you will say, "every sensible spectroscopist, whenever at least he is observing in a chamber upon any chemical element within his grasp, endeavours to make the illumination, or incandescence under which he looks at that particular matter, as bright as he possibly can."

Most certainly! That is exactly what he does, and even glories in doing; for he finds that he cannot make the said stuff too bright for the spectroscope, if only he preserves it at the same *temperature*. But precisely there comes in our envious and opposing lion; for almost every known attempt of man as yet to increase the brightness of a light, when at all successful in that respect, is found in the end to have enhanced its *temperature* amazingly. And if the temperature be so enhanced, where is the man who shall venture to predict, from theory alone, what the result will be in that potentially, most extensive, almost interminably long region of accurately measurable facts, the prismatic spectrum of light; wherein red is from violet, as far as north is from south?

Do you doubt there can arise any real and serious spectral changes from merely altering the temperature of one and the same flame of burning matter? Look at the metal lithium in any of its salts. How early in the history of spectroscopy did not that too little appreciated genius Fox Talbot show that chloride of lithium in a lamp flame formed one brilliant line in the scarlet-red and another very faint one in the orange-brown of the spectrum. Wherefore the brighter of them was called lithium α , the paler lithium β ; and the innocent, trusting public thought they would always know where, in the spectrum, by those letters as names, to find those lines.

But after the subsequent grand outcome of the full spectrum analysis of Professors Bunsen and Kirchhoff, and when not a few men insisted on rising from the mere beginnings of heating by flame, up to the ecstatic increase of temperature by the electric spark,—behold the lithium's red line, though still in exactly the same part of the spectrum's measured scale as before, has become woefully pale; the lithium orange line has burned up like a beacon; and far, far away in the comparatively distant regions of the spectral blue, there is a new line of almost rivaling brightness. Wherefore a new naming of the lines by Greek letters takes place among spark observers; the identical lithium β of flame-spectroscopy becoming lithium α of electric spark spectroscopy; a line hitherto unknown becoming lithium γ ; and poor old lithium α being known now only as lithium β .

But even that is not the end of the changes of brightness and name with increase of temperature; for pres-

* Read before the Royal Scottish Society of Arts, February 20, 1879.

ently still more ambitious geniuses increase the power of their galvanic batteries, the size of their induction coils, the length of their sparks, and then condense them both in time and space with Leyden-jar apparatus until the heat is something so fearful that, in the spectrum of one and the same lithium salt, it is no longer the red, nor the orange, nor even the blue line you care for now; but farther away in more distant spectral regions there burns a violet line; and beyond, yes, vastly further beyond that still, there arise exquisite lines in the ultra lavender and even grey wilds of spectral space. So then, to suit these altered brightnesses in the hotter condensed-spark spectrum, a new and yet more altered application of Greek letters, as names, takes place; and being attended to in their Memoirs by some persons, though not by others, will contribute to the future scientific confusion of many; and all on account of a mere change of temperature in a lithium light.

Or hear those first-class German observers MM. Plucker and Hittorf, at page 6 of the *Philosophical Transactions* for 1865, as to what still more extensive and positively wholesale and radical spectral changes, mere altered degrees of heat may work. "The first fact," say they, "which we discovered in operating with our tubes, guided by the above-explained principles, was the following one:—There is a certain number of elementary substances which, when differently heated, furnish two kinds of spectra of quite a different character, not having any line or band in common." So that if you have learned to recognise every line in the spectrum of, say, nitrogen at one temperature, it will not be by any of those lines, but by some perfectly different and unlikely-looking ones, that the element will manifest, or for a while conceal, itself at another temperature!

Neither does the application of a higher heat always brighten and improve a spectrum, as witness the element caesium, discovered by Professor Bunsen through means of the old flame spectrum analysis. What a refined and exquisite spectrum, too, does not caesium present in the lamp flame! So many lines it has, and all of them thin, sharp, classical almost in the orange, yellow, green; and then two gorgeous ones in the blue, but both of them so clearly defined, so admirably distinct, that I, in my small way, should have long ago established caesium as my prime standard reference in all lamp spectroscopy, if it had not been so dreadfully expensive.

Yet what becomes of this most valuable, almost invaluable, element caesium when promoted from mere flame to the higher temperature of the condensed electric spark? Alack! there is only then to be seen one faint solitary line, which has nothing in common with its departed brethren, and but little beauty of its own. With such a spectral calamity befalling poor caesium, I have been watchfully careful, in any attempted increase of the brilliancy of other spectra, to interfere as little as possible with their temperatures. And it is simply because I have recently proved the practical efficiency of a very easy method of accomplishing at least a considerable amount of brightening up, without any increase of heat whatever, in both flame and spark spectroscopy, that I have ventured now to lay the said method for merely what it may be worth, and to what extent it may be new, before the Royal Scottish Society of Arts.

(To be continued).

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Monday, March 31, 1879.

Dr. J. H. GLADSTONE, F.R.S., President, in the Chair.

This was the Anniversary Meeting of the Society.

The President presented his Annual Report on the state of the Society. The state of the Society affords

much ground for congratulation, the past year having been one of quiet prosperity. Various alterations have been made in the bye-laws, and the publication of the Society's *Journal* has been improved. 61 Fellows have been elected, and 18 have died, withdrawn, &c., during the past year, the present number of Fellows being 981. There are 34 Foreign Members and 1 Associate; 28 names are awaiting election. The Treasurer's report shows an increase of receipts over expenditure to the amount of £1964 9s. 5d. (including a legacy of £1000 from the late Mr. Sidney Ellis). 68 papers have been read before the Society during the past year. Lectures have been given by H. C. Sorby and S. H. Vines. The number of papers from 1859 to 1869 averaged 36 annually, fell as low as 22 in 1872, and since has rapidly increased. There is an increasing disposition to illustrate papers by experiments: this practice adds much to the interest of the meetings of the Society. On the 13th of November last Prof. Würtz delivered the Faraday Lecture at the Royal Institution, "Sur la Constitution de la Matière à l'état Gazeux." Those who were present will not readily forget the perfect lucidity, the rare manipulative skill, or the enthusiasm of the Lecturer on that occasion. The Council have carefully considered the condition of the Library and its rules. It has been resolved that no serial publication of which the Society does not possess a duplicate copy shall be taken away from the rooms. Duplicate copies of back numbers of *Liebig's Annalen* and the *Annales de Chimie et de Physique* have been ordered, and these works, together with other important serial publications, are now being taken in in duplicate. Many new books have also been ordered, and on this point the Council would be glad of suggestions from Fellows of the Society. Arrangements have been made for Fellows at a distance to have books sent to them on giving a written order and paying the cost of carriage. A new series of instructions has been drawn up for the use of abstractors. Great efforts have been made to publish the *Journal* within the first week of each month. The ventilation of the meeting-room has been much improved by the combined investigations of Mr. Perkin and Dr. Russell, and alterations suggested by them. A new plan of choosing the President has been adopted this year. As the Faraday Lecture occurs only once every three years, whilst the President is elected for two years, it was suggested that it would be better to elect some Fellow who has already filled the office of President for one year, so that the Faraday Lecture would occur in the second year of the next President's tenure of office. A separate Report of the Research Fund is submitted, the President suggesting that a portion might, with peculiar fitness, be devoted to the accurate determination of chemical constants. A short biography of each of the Fellows deceased was then read, viz., of M. Malaguti (Foreign Member) Messrs. W. Baker, A. Bird, W. A. Lyttle, W. A. Stewart, and J. Wiggan. The President concluded his address as follows:—"While there is much to encourage us in the progress of the past twelve months, I think I only express the general feeling when I say that we ought not to feel satisfied with present attainments. The Society exists 'for the general advancement of Chemical Science;' this means both the encouragement of research and the diffusion of the knowledge of new discoveries. With regard to the promotion of research, as our members now exceed 1000, and the laboratories of our land are growing in importance, we may surely look for a larger amount of original work in coming years: we should also seek, not only to add to previous knowledge, but to increase what I may venture to term the scientific culture of the workers. In our laboratories we are isolated, and are apt to look upon our own pet subject as of prime importance; but when we meet in these rooms, or turn over the pages of our *Journal*, we are carried away to many different fields of thought in succession. This promotes largeness of view, and must react favourably upon the cultivation of our individual corner of the great field. I trust that our Society will never devote its energies too exclusively to

one branch of our science, but will lay claim to its fair share of those borderlands in which the work of the chemist blends with that of the physicist, the geologist, and the physiologist. Scientific culture will also lead to a perception of what are the higher aims of chemical enquiry. The formation of new compounds is valuable, but we are liable to be encumbered by the richness and quantity of our materials, and to forget the necessity of grouping them together as a part of systematic knowledge. The construction of the most expressive formulæ is useful, but we must always be ready to modify these as the exigencies of further knowledge may require. We want, also, to know more of the chemical force itself, and how it acts; we want to distinguish those properties which are so profoundly connected with the ultimate molecules of matter that they are little, if at all, affected by chemical combination; from those which are the sport of every change; we want to study all the transformations of energy involved in the phenomena of dynamical chemistry, and to determine with precision how the chemical force is related to the other great forces of nature. As to the diffusion of chemical knowledge, our *Journal* is the main instrument in our hands for effecting this. But the new arrangements in regard to the lending of books from the Library will doubtless advance the same object. It is happily the case that a knowledge of chemistry is fast finding its way into our upper and middle class schools; and though our science is not recognised by the Government code, many attempts are being made to introduce into our elementary schools some primary knowledge of those facts and principles of nature which lie at the foundation of chemical and physical science. Technical education is also rising into favour, and the formation of a technical college is now engaging the attention of the great City companies. The Society, as such, can perhaps do but little in this direction, although the practical applications of chemistry are directly alluded to in our Charter, but its individual members may accomplish much.

Dr. ARMSTRONG then read a list of grants from the Research Fund made during the past year:—£50 to Mr. Hartley for an Investigation of the Absorption of the Ultra-violet Rays of the Spectrum by Organic Substances; £30 to Dr. W. Ramsay for Determining the Electric Conductivity and Resistance of Solutions of Salts at Different Temperatures; £50 to Dr. Tilden for an Investigation into the Chemical Nature of the Terpenes; £10 to Mr. Shenstone for an Examination of Certain Reactions of Brucine and Strychnine; £20 to Mr. W. Jago for a Research on the Organic Matter in Sea Water; £20 to Mr. Francis Jones for the Investigation of Boron Hydride; £15 to Mr. F. D. Brown for the Experimental Study of the Theory of Fractional Distillation; £10 to Dr. Burghardt for the Investigation of the Constitution of Topaz; £15 to Prof. Thorpe for the Investigation of Abietine; £30 to Dr. Dupré for the Estimation of the Organic Carbon in Atmospheric Air. The following gentlemen who have received grants have communicated papers to the Society:—Messrs. Johnson, Carleton Williams, Drs. Harrow and Wright; Mr. Hartley in conjunction with Mr. Hartington has presented his first results to the Royal Society, *Proceedings*, xxviii., 233. The following gentlemen, who, for various reasons, have not yet communicated papers, have sent in reports to the Committee:—Drs. Crow, Carnelly, Tilden, and Ramsay; Messrs. Bedson, Neison, Shenstone, and Jago.

Dr. ODLING then moved a vote of thanks to the President and the adoption of his report. It was very gratifying to hear such a flourishing report, and thought the Fellows might congratulate themselves on having had such a President.

Mr. NEISON, in seconding the motion, urged that a copy of the General Index should be presented to every Fellow of the Society.

Dr. WRIGHT suggested that the hours during which the

library was open in the evening should be extended from seven to nine to seven to ten.

The motion was then carried by acclamation.

The PRESIDENT felt greatly honoured by the cordial manner in which the motion had been received and the kind way in which Dr. Odling had introduced it. He had experienced much pleasure during his occupation of the chair, which any chemist would be proud to occupy. He was very grateful for the way in which the Council and the Society had seconded him in everything.

The TREASURER (Dr. Russell) then read his account of the finances of the Society. The state of the Society was very satisfactory. The income for the year was £2350; the expenditure £2300. The balance in hand of the Research Fund amounted to about £230.

Mr. FRISWELL then read the report of the Auditors, Messrs. Spiller, Thomson, and Friswell.

Dr. THUDICHUM had listened with great satisfaction to the statement of the Treasurer. After making a few remarks as to the present method of electing Fellows, Dr. Thudichum proposed a cordial vote of thanks to the Treasurer, who had performed his important duties in the most perfect manner the Society could wish.

Dr. GILBERT seconded the motion, which was carried unanimously, with much pleasure.

Dr. RUSSELL returned thanks to the meeting.

Mr. NEISON proposed a vote of thanks to the officers and Council.

This was seconded by Mr. GROSJEAN, and carried unanimously.

Mr. PERKIN replied.

Votes of thanks were subsequently given to the Auditors, the Editors, Abstractors, and the Reporter of the Society.

The following officers were then announced from the chair as having been duly elected for the ensuing year:—President, Warren De La Rue, F.R.S.; Vice-Presidents, F. A. Abel, C.B., Sir B. C. Brodie, E. Frankland, J. H. Gladstone, A. W. Hofmann, W. Odling, Lyon Playfair, A. W. Williamson, F. Field, J. N. Gilbert, N. S. Maskelyne, H. E. Roscoe, R. Angus Smith, J. Young; Secretaries, W. H. Perkin, H. E. Armstrong; Foreign Secretary, Hugo Müller; Treasurer, W. J. Russell; other Members of the Council, M. Carteighe, A. H. Church, W. N. Hartley, C. W. Heaton, E. Riley, W. C. Roberts, W. A. Tilden, W. Thorpe, T. E. Thorpe, J. T. W. Thudichum, R. V. Tuson, R. Warington.

PHILOSOPHICAL SOCIETY OF GLASGOW.

CHEMICAL SECTION.

Ordinary Meetings.

Mr. JAMES MACTEAR, President, in the Chair.

"On the Manufacture of Phosphorus," by Mr. JAMES READMAN. The author remarked at the outset that his communication contained nothing absolutely new, but was simply an account of the practical aspects of the phosphorus manufacture. Various mineral phosphates are now used in the manufacture of phosphorus; bone-ash is no longer remunerative, on account of its high price. Among the varieties of mineral phosphate are—Canadian phosphate, German or Nassau phosphate, Charleston phosphate, and Sombbrero phosphate. The first stage in the manufacture of phosphorus is to decompose the calcium phosphate completely in a large cylinder with sulphuric acid of 110° to 115° Twaddle, with constant agitation. The calcium sulphate is then filtered off, and the filtrate is evaporated to about 80° or 90° T., and then allowed to cool. It contains over 25 per cent of P_2O_5 . It is then mixed with coarse wood-charcoal, and dried in a muffle-furnace. The proportion of charcoal to liquor is 1 to 5. This substance contains the phosphoric acid in a partially insoluble state, so that it is different in its properties from

meta-phosphoric acid. The mixture is then transferred to retorts of Stourbridge clay, capable of holding 30 to 40 lbs. The malleable iron pipe through which the phosphorus distils is then luted on, and the heat is raised to bright redness. The phosphorus distils over, and is condensed in water. It only remains to cast it in moulds, when it is sent to market. Mr. Readman, in contradiction to the usual assertions in text-books, called especial attention to the fact that mono-calcium phosphate is not used as a source of phosphorus, for the calcium takes up valuable room, and the compound requires a much more intense heat to effect its decomposition. Redonda phosphate of aluminium is regarded by the author as the future source of phosphorus, but as yet no attempt to procure phosphorus from it has been peculiarly successful.

The PRESIDENT read a paper on the "*Leblanc Soda Process*." He gave an historical *resumé* of the process of alkali manufacture, mentioning that before Leblanc brought out his process it was very probably carried on as a secret process in England. The various reactions imagined by different investigators to take place were then alluded to. Among these the following was given by Dumas:—

It was afterwards supposed that an oxysulphide of calcium was formed in virtue of the equation—

and Gossage represented the reaction as—

The author then gave an account of his own researches on the subject. As it is impossible to arrive at any definite conclusion by operating on the large scale, for different samples of black-ash, even when drawn with the greatest possible care from the same charge, show the most varied composition, the reaction was simplified, sodium sulphate and carbon being heated together in small quantity: the proportions and temperature were varied in each experiment. Some preliminary experiments were made, and proved that sodium carbonate is formed, especially at a red heat. At a higher temperature very little Na_2CO_3 was produced. The reaction evidently approximated to—

At 1250° F. the reaction between sodium sulphate and carbon in a closed crucible is represented by the equation—

In an open crucible the excess of sulphur is burned off, and it is probable that if more carbon were added all the sulphate of sodium would be converted into carbonate. On raising the temperature the Na_2S_2 and Na_2CO_3 are decomposed, and the only products are $\text{Na}_2\text{S} + \text{CO}$.

The next paper was read by Mr. COLEMAN. Its subject was "*The Liquefaction of Gases*." The author gave a description of his apparatus for liquefying hydrocarbons with low boiling-points obtained in the distillation of shale, and explained it on theoretical principles.

NOTICES OF BOOKS.

The Science Index: a Monthly Guide to the Contents of the Scientific Periodicals. January, 1879. Vol. I., No. 1.

We were very much pleased with the fundamental idea of this journal as conveyed in its title, but on looking further we experienced no small degree of disappointment. A relatively trifling portion of the space is devoted to science, whilst the lion's share is allotted to the industrial arts and to commerce. Thus, of the 112 columns, chemistry receives 3; astronomy, $1\frac{1}{2}$; electricity, $1\frac{1}{2}$; natural history, 1; physics, 2; geology, $1\frac{1}{2}$; botany, $\frac{3}{4}$; math-

matics, $\frac{1}{2}$; whilst physiology and psychology are absent altogether. On the other hand, architecture is favoured with 8 columns, commerce with 4, capital and labour with the same space, lawsuits with 2, and railways with 4. Hence we submit that the new periodical is altogether wrongly named. We observe, further, that the French, German, and other Continental scientific journals do not appear to be indexed. Amongst our American contemporaries the *Scientific American* with its supplement is alone selected, to the exclusion of not a few journals of high and recognised value. Many British periodicals are also overlooked. Thus we see no mention of the *Chemist and Druggist*, the *Pharmaceutical Journal*, the *Analyst*, the *Sugarcane*, &c. The medical journals are omitted in a body, as are also several important papers devoted to various branches of natural history. Now it must be clear that a partial and incomplete index is of very doubtful value. A student hears a rumour concerning a certain memoir which has appeared. He searches the "Science Index," and finding no mention of it is led to conclude that it does not exist, the fact being that it is to be found in some journal which has here been overlooked.

Another defect is that certain memoirs are credited not to the journals in which they first appeared, but to others in which they have been reproduced. Typographical errors are also too numerous, and in certain cases are of a misleading character.

If the editor in future issues will attend to these suggestions he may achieve a decided success. But we must confess ourselves unable to recommend the January number as a "Science Index."

The Textile Colourist. Vol. I., No. 1.

This is a new periodical devoted to dyeing, bleaching, printing, &c., and has just appeared at Philadelphia under the management of Dr. Frank. It contains a number of practical recipes illustrated by well dyed samples of dyed yarns, trimmings, &c. Concerning the chapter on mordants, by M. P. Prunier, we will merely remark that he gives the name "iron liquor," not as usual to the acetate of iron, but to a nitro-sulphate, and that he terms his perchloride of tin "red liquor," a name formerly peculiar to the acetate of alumina. This, we fear, will lead to further confusion in a nomenclature which is already complicated enough.

We wish our new contemporary a prosperous and a useful career.

CORRESPONDENCE.

MANUFACTURE OF SULPHURIC ACID.

To the Editor of the Chemical News.

SIR,—Since in your review of a new treatise on the manufacture of sulphuric acid my authority is referred to on a special point, that of the introduction of nitric acid in the liquid form, I feel bound to state that I am no longer so decidedly in favour of that system as I certainly was some years ago. Having investigated this matter very carefully, along with all other points of sulphuric acid and alkali making, on visits to the prominent English, German, Austrian, and French Alkali works, I have come to the conclusion that, *on the whole*, the decomposition of the nitrate and sulphuric acid by the heat of the burner gas, as practised in England and at many Continental works, is the better plan, *if carried out in the proper way*. In that case the consumption of nitrate is just as low as when employing nitric acid in the liquid form. The difference between the two plans, as far as cost and convenience are concerned, is certainly very slight now, since the nitric acid is now no longer introduced by "cascades"

but it is, by some of the most careful German and Austrian manufacturers, simply run down the Glover tower, all fear of any appreciable loss of nitrous compounds in that tower having vanished. I cannot, of course, explain these matters in detail here; this is done in my "Treatise on the Alkali Manufacture," the first volume of which (Sulphuric Acid) has just been published in German, whilst the English edition (published by Mr. John van Voorst) is far on its way through the press.—I am, &c.,

GEORGE LUNGE.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 10, March 10, 1879.

This issue is taken up with the annual presidential address and with an account of the awards of the various prizes offered for certain branches of research. One of these reports, relative to the prize awarded to M. Turpin for his non-poisonous pigments, requires notice. These, we are told, include not merely certain colours long known, such as zinc-white and chromate of zinc (I) but "others which are new and absolutely inoffensive, as they derive their origin from coal-tar." Is not this a somewhat hazardous conclusion?

Bulletin de la Société Chimique de Paris,
No. 3, February 3, 1879.

Researches on Strychnine.—H. Gal and A. Etard.—The authors, on treating strychnine with hydrate of baryta, have obtained two new hydrated bases, di- and trihydro-strychnine.

On Succinic Fermentation.—P. Miquel.—The author has detected the bacterium which effects the decomposition of asparagin into succinate of ammonia. It is a mobile organism formed of one, two, or rarely of a greater number of joints. The mature being and its germs are destroyed by a temperature of 48° to 49° kept up for two hours.

Dextro-rotatory Amylic Alcohol.—J. A. Le Bel.—Lævo-rotatory amylic alcohol, indicating -4.33° for 10 centimetres of a liquid column may be rendered inactive by its transformation into amylate of sodium and by the action of an elevated temperature upon the latter. The author separates the dextro-rotatory alcohol from the inactive kind by destroying a portion of the lævo-rotatory kind by moulds.

Action of Diastase, Saliva, and Pancreatic Liquid upon Starch and Glycogen.—F. Musculus and J. de Méring.—Already noticed.

Aniline and the Methylated Toluydins, and on their Coloured Derivatives.—P. Monnet, F. Reverdin, and E. Noelting.—The authors describe mono-methyl-aniline, dimethyl-aniline, mono-methyl-ortho-toluydin, dimethyl-ortho-toluydin, mono-methyl-meta-toluydin, dimethyl-meta-toluydin, and dimethyl-para-toluydin. It results from their researches that among all the bases found in commercial methyl-aniline pure dimethyl-aniline itself is the only one which can be advantageously used for the manufacture of violet. Mono-methyl-aniline and dimethyl-ortho-toluydin give, indeed, good violets of a redder tone than that of dimethyl-aniline, but the yield is very trifling. Mono-methyl-ortho-toluydin gives a good return of violet, but it has the defect of being insoluble in water. The methylated derivatives of the two other toluydins yield brown and grey colours of no value.

Gazzetta Chimica Italiana.

Anno viii., 1878. Fasc. viii. and ix.

Cumo-phenol-carbonic Acid.—E. Paterno and G. Mazzara.—This acid takes the form of flat needles or nacreous laminæ, which melt at 120.5° and volatilise without decomposition; sparingly soluble in cold water, more so in hot water, and very soluble in alcohol and ether. The aqueous solution yields with ferric salts a very intense violet-blue colouration. Its composition is expressed by the formula $C_{10}H_{12}O_3$. The authors have examined its barium, lead, and silver salts.

Alleged Existence of Oxygenated Water in the Organism of Plants.—Prof. Giuseppe Belucci.—The presence of hydric peroxide in the juices of plants was first admitted by Schœnbein, and was maintained more recently by Clermont. The assumption is refuted by the author's experiments.

Two Propyl phenols and other Derivatives of Propyl-benzol.—Dr. P. Spica.—The author describes synthetic propyl-benzol obtained by the method of Fittig, Schäffer, and König, its sulph-acids and the α - and β -derivatives of the latter.

Dimorphism of the Aceto-toluides.—Dr. R. Panebianco.—An optical and crystallographical study, not admitting of useful abstraction.

Synthesis of Phenyl-cinnamic Acid.—Dr. A. Ogliarolo.—The author obtains the new acid by heating in a reflux apparatus for eight hours, at a temperature of 150° to 160° , about 25 grms. of phenyl-acetate of sodium, previously dried at 110° to 120° , with 16 grms. of benzoic aldehyd and 60 of anhydrous acetic acid. The product of the reaction, which, when hot, is entirely liquid, condenses on cooling to a reddish brown crystalline mass, which is diluted with water and boiled to expel the excess of acetic acid employed. The result is filtered when the filtrate deposits the acid in white needles.

Preparation of Ammonialdehyds with Mixed Radicles.—R. Schiff.—An examination of the action of benzoic aldehyd upon chloral-ammonium and butyl-chloral-ammonium.

Studies on Teucrium Fruticans.—Dr. A. Ogliarolo.—The author has obtained from this plant a compound which he provisionally names teuclin, and has examined its behaviour with nitric and sulphuric acids.

Chemical Nature of the Essence of Laurocerasus and of Bitter Almonds.—Dr. M. Fileti.—The author has studied the action of nascent hydrogen upon this essence and upon amygdalin.

The Alkaline Polysulphides as Reagents for Cobalt.—G. Papasogli.—Among the characteristic reactions of cobalt is one founded upon the blood-red colouration (or rose, in small quantities) obtained if there is poured into the solution of the double cyanide of cobalt and potassium some nitrite of potassium with nitric acid. A similar colouration is obtained if, instead of adding nitrite of potassium and nitric acid to the above-mentioned cobalt solution, there is added a little drop of a solution of a yellow alkaline sulphide. In order that the reaction may be most sensitive the polysulphide should be added in such a manner that the two liquids may not completely mix but form two distinct strata. If cobalt is present the plane of separation will show a blood-red, more or less intense according to the quantity of the metal. The author has obtained this reaction with $\frac{1}{2}$ c.c. of a liquid containing 0.0005 grm. of cobalt. The presence of nickel does not interfere.

Glucoside of Liquorice.—Prof. F. Sestini.—Not susceptible of useful abstraction.

Chemiker Zeitung.

No. 9, 1879.

Sugared Ultramarine.—C. Fürstenau.—The Austrian ultramarine manufacturers sophisticate their colours with

COMPOSITION AND QUALITY OF THE METROPOLITAN WATER.

FEBRUARY, 1879.

The following are the returns of the Society of Medical Officers of Health:—

	Appearance in a foot Tube.	Ammonia.		Nitrogen as Ni- trates, &c.	Oxygen used to Oxidise Organic Matter.	Total Solids.	Lime.	Magnesia	Chlorine	An- Sulphuric hydride.	Hardness on Clark's Scale.	
		Saline.	Organic.								Before Boiling.	After Boiling.

The quantities of the several constituents are stated in grains per imperial gallon.

NOTE.—The amount of oxygen required to oxidise the organic matter, nitrites, &c., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

C. MEYMOTT TIDY, M.B.

3 parts of gypsum, and lest the colour should appear too pale it is further mixed with glycerin or glucose, or a mixture of both. This keeps the powder damp and renders the colour apparently deeper.

Formation of Ammonium Nitrite.—V. Löseke.—When water evaporates in air a little ammonium nitrite is always formed. The author shows that this takes place at the expense of the free nitrogen of the atmosphere, more of which enters into combination at low than at high temperatures.

Industrial Activity.—At a general meeting of the German Distillers' Association it was resolved to establish and maintain a chemical laboratory, an experimental distillery, a school of distilling, a trade journal, a glass-blowing establishment (for the manufacture of normal hydrometers), and an office for general intelligence.

No. 10, 1879.

Chloride of Lime.—Dr. Filsinger.—The author states that in case of English samples the importers have very frequently to complain of differences in strength, whilst in German qualities important deviations from the stipulated strength are almost unknown.

Spurious Seeds.—According to Dr. A. Stutzer the manufacture of artificial clover seed is now a flourishing business in Germany. Fragments of gravel of a suitable size are obtained by sifting, and are then agitated with certain colouring matters in a revolving drum till their appearance is considered satisfactory.

Unwholesome Honey.—A sample of honey which had occasioned illness on consumption was found when microscopically examined to contain multitudes of Acari (*Glyciphagno prunorum* and *agilis*).

Manufacture of Picric Acid.—J. Marzelli proposes to add slowly the sulphacid of phenol to concentrated nitric acid. The reaction proceeds slowly without requiring the application of heat. The crystals of crude picric acid are washed in cold water, pressed, and recrystallised.—*Monit. Prod. Chimiques*.

Cerium Aniline-Black.—J. Lytsche, of St. Petersburg, has used this process successfully for upwards of a year, employing a cerous sulphate formed by dissolving the cerite of Riddarhytta, in Sweden, in sulphuric acid. The black is said to be faster than that produced with vanadium.—*Engl. Polyt. Journ.*

No. 11, 1879.

Utilisation of Animal Refuse.—Dr. B. Terne.—The author points out that offensive gases are invariably generated when fresh animal matters are boiled by means of steam at a high pressure, and recommends that they should be gradually passed through the furnace.

Sensitiveness of Chemical Balances.—A. Verbeek.—The author, by his compensating arrangement of the axial knife-edges of the balance, renders it equally sensitive when loaded as when empty.

Saccharification of Starch.—M. Riban.—If starch is soaked for a year in a cold saturated solution of common salt it is gradually converted into glucose.

Reaction of Bile Pigments in Urine.—About 2 grms of the urine are poured into a test-tube, acidulated with 2 or 3 drops of concentrated sulphuric acid, and a small crystal of potassic nitrite is introduced, taking care that it does not fall upon the side of the tube. If bile pigments are present splendid grass-green stripes are immediately formed in the liquid.—*Repertoire de Pharmacie*, 35, 58.

Les Mondes, Revue Hebdomadaire des Sciences.

No. 10, March 6, 1879.

M. Adam lays great emphasis on the use of soot in horticulture and agriculture as a means of destroying or banishing noxious insects.

MISCELLANEOUS.

Russian Scientific News.—Some experiments executed in Cronstadt, have shown that an explosion of two grammes of nitro-mannite, placed into a capsule, produces a full detonation of damp gun-cotton, containing at least 25 per cent of water. The explosion of the nitro-mannite was effected by the explosion of 0'2 grm. of mercury fulminate, and in other experiments by using the same amount of diazo benzol nitrate. Other fulminating compounds (KClO_3 , $\text{C}_6\text{H}_2(\text{NO}_2)_3$, OK) gave the same effect, but the quantity of them, wanted for the same purpose, exceeds 1 grm.

M. Adrianovsky reports on the action of aluminium chloride on acetic and sulphurous anhydrides. Acting by aluminium chloride on acetic anhydride at ordinary tem-

perature acetyl chloride and aluminium acetate are produced. Sulphurous anhydride with Al_2Cl_6 gives a compound having the following composition:— $AlCl_2SO_2Cl$. This reaction takes place at ordinary temperature, but is more easily conducted at 50° to 60° Celsius.

Prof. Bexetoff has made some new experiments on the absorption of hydrogen by palladium, and determined the atomic heat of the hydrogen when alloyed with palladium. The atomic heat was found to be 5.88. 25.0938 grms. of palladium in the form of wire and strips were used for the experiment. The metal absorbed 0.1418 grm. of hydrogen, corresponding to 1575 c.c.; in other words, the palladium absorbed 710 volumes of the hydrogen.

SERGIUS KERN, M.E., St. Petersburg

NOTES AND QUERIES.

Testing of Coal-Tar Products.—Can any of your readers recommend a book on the commercial testing of coal-tar products?—T. C. W.

Gases from Vitriol Chambers.—(Reply to W. L.)—You will find the information you desire in our new work on sulphuric acid, published by Sampson, Low, and Co., 188, Fleet Street, E.C., and noticed in last week's CHEMICAL NEWS.—LOCK AND LOCK.

TEXT-BOOKS OF SCIENCE.

Now ready, with 6 Plates and 88 Woodcuts and Diagrams, in small 8vo., price 4s. 6d. cloth,

THE STUDY OF ROCKS, an Elementary Text-book of Petrology. By FRANK RUTLEY, F.G.S., of Her Majesty's Geological Survey.

"We strongly recommend this work to all who are entering upon the study of geology, and who wish at the outset to lay a firm foundation."—*Journal of Science*.

"We desire to call attention to this work, which ought to have a peculiar attraction for a large number of our readers. We cannot refrain from recommending to special attention the short but able description of the definition and origin of Rocks, which forms the subject-matter of the second chapter."—*Mining World*.

London: LONGMANS and CO.

NOTICE TO ADVERTISERS.

In consequence of GOOD FRIDAY occurring in the ensuing week, the CHEMICAL NEWS will be published on Thursday next, April the 10th. Advertisements must therefore be forwarded to the Office not later than 2 o'clock on Wednesday, the 9th instant.

An Assistant Chemist wanted in a London Sugar Refinery. Salary £40. Must have experience in saccharometry.—M. W., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Advertiser, with considerable practical experience as Sugar and Brewing Chemist, is wishing to meet a position where his knowledge would prove of service. High testimonials and references.—Address, M. N. T., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Situation wanted by a Competent Analyst as Assistant or Principal. Good teacher. Apply, Public Analyst, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

The Runcorn Soap and Alkali Co., Limited. Runcorn, are in want of a Youth in the Laboratory as an Apprentice for three or four years.—Apply by letter only to the Runcorn Soap and Alkali Co., Limited, Runcorn.

Wanted, by a Gentleman (age 19), an Appointment in an Analytical Laboratory. Has been practically acquainted with general analysis for two years in the laboratories of the Pharmaceutical Society. References permitted to Prof. of Attfield.—Address, E. A. R., Oxford Villa, Montague Road, Uxbridge, Middlesex.

Wanted, an Under-Assistant in a Chemical Laboratory in London; must have a general knowledge of chemistry and good references.—Apply by letter only to G. Ansell, 30, Duke Street, Piccadilly, W.

FILTER-PRESS.

Wanted, a Second-hand Filter-Press in Iron or Lead.—Full particulars to Theta, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

NITRATE OF IRON.

Wanted, offers for solution; strength 20° to 22° Baumé. Anyone taking regular deliveries could have it upon very advantageous terms.—Address, Box 173, Post Office Sheffield.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy Manure; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw, near Clayton, Manchester.

TO BE LET, at best offer obtainable, Complete Copper Extracting Works and Complete Phosphorus Works; Acid Chambers adjoining.—Address in first instance, G. J. Blower, 38, Lowe Street, Whitmore Reans, Wolverhampton.

TO PAPER MAKERS, CHEMICAL MANUFACTURERS, AND OTHERS.

TO LET, at Low Rentals, Works and Land in Plots of Two to Ten Acres, near Swansea. Coals obtainable from 4s. 6d. per ton. Water good and abundant. Any description of manufactory can be carried on. Excellent Railway, Canal, and Dock accommodation close at hand.—Apply to Richard Hall, Esq., 37, Great George Street, Westminster, or Mr. Thomas Williams, Aberdula, Neath, Glamorganshire.

BERNERS COLLEGE of CHEMISTRY.

Instruction and preparation in CHEMISTRY and the EXPERIMENTAL SCIENCES under the direction of Professor E. V. GARDNER, F.A.S., M.S.A.

The Class Rooms are open from 11 to 5 a.m. and from 7 to 10 p.m. daily.

Special facilities for persons preparing for Government and other examinations.

Private Pupils will find every convenience.

Analyses, Assays, and Practical Investigations connected with Patents, &c., conducted.

Prospectuses and full particulars on application to Prof. Gardner at Berners College, 44, Berners-street, W.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.

LIST OF OFFICERS AND COUNCIL.

President—E. FRANKLAND, Ph.D., D.C.L., F.R.S., &c.

VICE-PRESIDENTS.

 Fellows and Associates are requested to give notice of Change of
 Address to the Secretary.

INSTITUTE OF CHEMISTRY.

The President has offered Two Prizes of £50
 each for the two best original investigations involving Gas
 Analysis. These Prizes will be open to Associates, and to all non-
 Fellows of the Institute who shall before the 31st December next have
 qualified for the Associateship in all respects short of passing the pre-
 scribed practical examination, and successful competition for these
 prizes will be accepted in lieu of such practical examination.—Further
 information may be obtained on application to the Secretary, Mr.
 C. E. GROVES, Somerset House Terrace, W.C.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.—SUMMER SESSION, 1879.

Lectures and Clinical Instruction will commence on Thursday
 May 1.—For Prospectus with full details apply to the Dean or the
 Resident Medical Officer at the Hospital.

The Prestolee Alkali Works, Farnworth, near Bolton, Lancashire,
 fitted with costly Plant, Machinery, and Apparatus for the Manu-
 facture of Soda-ash, Bleaching-powder and Liquor, and Sulphuric
 Acid, in complete working order, with possession.—Preliminary.

MESSRS. FULLER, HORSEY, SONS,
 and CO. are instructed to SELL by AUCTION, at the Palatine
 Hotel, Manchester, on Thursday, April 17, at 3 o'clock precisely, in
 one lot, unless an acceptable offer be previously made by private con-
 tract, the PRESTOLEE ALKALI WORKS, a freehold property,
 having a superficial area of 95,741 square yards of land, subject to
 chief rents amounting to £407 13s. 9d. per annum, with the building,
 plant, machinery, and apparatus erected thereon, capable of manu-
 facturing monthly a product exceeding in the aggregate 2000 tons of
 soda-ash, bleaching-powder and liquor (by Weldon's patent process),
 and sulphuric acid, also caustic soda and muriatic acid. The amount
 expended in the construction of these works has been very large. A
 valuation was made with great care in 1874 by Messrs. Holmes and
 Son, the well-known valuers, of Manchester; their estimate then
 amounted to £99,000, and since that time a sum exceeding £10,000
 has been expended. The whole of the works and plant have been
 well kept, and are conveniently arranged for working. The Bury,
 Bolton, and Manchester Canal, which forms one boundary of the
 property, affords facility for economical water carriage, and the
 Lancashire and Yorkshire Railway is within a very short distance.
 There is a plentiful supply of water for all manufacturing purposes,
 free of cost, from the river Croal, and coals are raised from pits in
 the immediate neighbourhood. Pyrites, salt, lime, and limestone are
 all brought by boats direct to the wharf on the canal. The works
 may be economically worked with a small capital, as arrangements
 may be made with the vendors for a very considerable portion of the
 purchase money to remain upon mortgage. Large profits have been
 realised in the past, and the high reputation of the Prestolee manu-
 factures in the market will ensure to an energetic man, even at the
 existing low prices, an ample return for his capital invested and
 possession of works not surpassed for completeness or compactness
 by any in the kingdom. May be viewed till the sale. Printed par-
 ticulars are in course of preparation, and may shortly be had at the
 Works; at the Palatine and Queens Hotels, Manchester; of Messrs.
 Wakeman and Bleack, Solicitors, Warminster; of Messrs. Addleshaw
 and Warburton, Solicitors, Norfolk Street, Manchester; and of
 Messrs. Fuller, Horsey, Sons, and Co., 11, Billiter Square, London,
 who are empowered to treat for the disposal by private contract, or
 an offer for renting would be entertained.

WILLIAM AND WILLIAM T. FIELD,
 MANUFACTURERS of the Celebrated
 STAFFORDSHIRE BLUE BRICKS, specially adapted for
 Chemical Plant, i.e., Acid Towers, &c. Also all other kinds of Best
 Staffordshire Blue Bricks, Pavings, Plyths, Splays, Copings, &c.
 &c. Prices and samples on Application.

TESTIMONIAL.

"We have used the Blue Staffordshire Brick for Sulphuric Acid
 Towers, &c., manufactured by Messrs. Field, for the last fifteen years,
 during which time they have given great satisfaction. We recommend
 them to the Chemical Trade, believing there is nothing better in the
 market."—(Signed) WILLIAM HUNT and SONS, Lea Brook
 Alkali Works, near Wednesbury, Staffordshire, February, 1878.

TOLL END BRICKWORKS,
 TIPTON, STAFFORDSHIRE.

MAGENTA RESIDUES,
 AND FREE FROM LIME.

THE CHEMICAL NEWS.

Vol. XXXIX. No. 1011.

CONTRIBUTIONS TO MOLECULAR PHYSICS IN HIGH VACUA.

By WILLIAM CROOKES, F.R.S.

THIS Paper is a continuation of one "On the Illumination of Lines of Molecular Pressure, and the Trajectory of Molecules," which was read before the Royal Society on the 5th of December last. The author has further examined the action of the molecular rays electrically projected from the negative pole in very highly exhausted tubes, and finds that the green phosphorescence of the glass (by means of which the presence of the molecular rays is manifested) does not take place close to the negative pole. Within the dark space there is absolutely no phosphorescence; at very high exhaustions the luminous boundary of the dark spark disappears, and now the phosphorescence extends all over the sensitive surface. Assuming that the phosphorescence is due either directly or indirectly to the impact of the molecules on the phosphorescent surface, it is reasonable to suppose that a certain velocity is required to produce the effect. The author adduces arguments to show that within the dark space, at a moderate exhaustion, the velocity does not accumulate to a sufficient extent to produce phosphorescence, but at higher exhaustions the mean free path is long enough to allow the molecules to get up sufficient speed to excite phosphorescence. At a very high exhaustion there are fewer collisions, and the initial speed of the molecules close to the negative pole not being thereby reduced, phosphorescence takes place close to the pole.

Experiments are described in which a pole folded into corrugations is used at one end of a tube, the pole at the other end being flat set obliquely to the axis of the tube, and having a plate of mica in front pierced with a hole opposite the centre of the pole. The questions which this apparatus was designed to answer are:—(1.) Will there be two sets of molecular projections from the corrugated pole when made negative, one perpendicular to each facet, or will the projection be perpendicular to the electrode as a whole, *i.e.*, along the axis of the tube? (2.) Will the molecular rays from the oblique flat pole, when this is made negative, issue through the aperture of the screen along the axis of the tube, *i.e.*, direct to the positive pole, or will they leave the pole normal to the surface and strike the glass on its side? With the corrugated pole experiment shows that at high exhaustions molecular rays are projected from each facet to the inner surface of the tube, where they excite phosphorescence, and form portions of ellipses by the intersection of the planes of molecular rays with the cylindrical tube. When the oblique flat pole is made negative, a stream of molecules shoots from it nearly normal to its surface, and those which pass through the hole in the plate of mica strike the side of the tube, forming an oval patch of a green colour.

The oval patch in this apparatus happens to fall on a portion of the glass which has previously had its phosphorescence excited by the molecular discharge from the other corrugated pole. The phosphorescence from this pole is always more intense than that from the flat pole, and the glass, after having been excited by the energetic bombardment, ceases to respond readily to the more feeble excitement from the flat pole. The effect, therefore, is, that when the oval spot appears, it has a dark band across it where the phosphorescence from the other pole had been

taking place. The glass recovers its phosphorescent power to some extent after rest.

In this apparatus a shifting of the line of molecular discharge is noticed. If the coil is stopped and then set going repeatedly, always keeping the oblique pole negative, the spot of green light occurs on the glass at the spot where it should come supposing the discharge were normal to the surface of the pole. But if once the flat pole is made positive, the next time it is made negative the spot of light appears nearer the axis of the tube, and instantly shifts to its normal position, where it remains so long as its pole is made negative. There seems no limit to the number of times this experiment can be repeated.

A suggestion having been made by Professor Stokes that a third, idle, pole should be introduced between the negative and positive electrodes, experiments are described with an apparatus constructed accordingly. The potential of the idle poles (of which there are two) at low exhaustions is very feebly positive; as the exhaustion gets better the positive potential increases, and at a vacuum so good as to be almost non-conducting, the positive potential of the idle poles is at its greatest. The result is that an idle pole in the direct line of fire between the positive and negative poles, and consequently receiving the full impact of the molecules driven from the negative pole, has a strong positive potential.

It is found that when the shadow of an idle pole is projected on a phosphorescent screen the trajectory of the molecules suffers deflection when the idle pole is suddenly uninsulated by connecting it with earth. The same result is produced by connecting the idle pole with the negative wire through a very high resistance, such as a piece of wet string, instead of connecting it with earth. A tube, which has already been described in a paper read before the Royal Society on December 5th last, is used to illustrate this deflection. The shadow of an aluminium star is projected on a phosphorescent screen. So long as the metal star is insulated the shadow remains sharp, but on uninsulating the star by connecting it with an earth wire the shadow widens out, forming a tolerably well-defined penumbra outside the original shadow, which can still be seen unchanged in size and intensity. On removing the earth connexion the penumbra disappears, the umbra remaining as before.

It is also found that the shadow of the star is sharply projected when it is made the positive pole, the negative pole remaining unchanged.

These experiments are explained by the results just mentioned, that the idle pole, the shadow of which is cast by the negative pole, has strong positive potential. The stream of molecules must be assumed to have negative potential; when they actually strike the idle pole they are arrested, but those which graze the edge are attracted inwards by the positive potential and form the umbra. When the idle pole is connected with earth, its potential would become zero were the discharge to cease; but inasmuch as a constant supply of positive electricity is kept up from the passage of the current, we must assume that the potential of the idle pole is still sufficient to more than neutralise the negative charge which the impinging molecules would give it. The effect, therefore, of alternately uninsulating and insulating the idle pole is to vary its positive potential between considerable limits, and consequently its attractive action on the negative molecules which graze its edge. The result is a wide or a narrow shadow, according to circumstances.

After a definite shadow is produced, it is found that increasing the exhaustion makes very little change in the umbra, but it causes the penumbra to increase greatly in size. Experiments recorded in the paper already quoted have proved that the velocity of the molecules is greater as the vacuum gets higher, and consequently the trajectory of the molecules under deflecting action, whether of a magnet or of an insulated idle pole, is flatter at high than at low vacua.

An experiment is next described, having for its object to

ascertain whether two parallel molecular rays from two adjacent negative poles attract or repel each other. It is considered that if the stream carries an electric current, attraction should ensue, but if they are simply streams of similarly electrified bodies, the result would be repulsion. Experiment proves that the latter alternative happens, lateral repulsion taking place between two streams moving in the same direction.

Many experiments are given to illustrate the law of action of magnets on the molecular stream, but the results are of too complicated a character to bear condensation without the diagrams accompanying the original paper.

The molecular stream is sufficiently sensitive to show appreciable deflection by the magnetism of the earth.

The author, after numerous experiments, has succeeded in obtaining continuous rotation of the molecular stream under the influence of a magnet, analogous to the well-known rotation at lower exhaustions. Comparative experiments are given with a "high vacuum" tube, where no luminous gas is visible, but only green phosphorescence on the surface of the glass, and a "low vacuum" tube in which the induction spark passes in the form of a luminous band of light joining the two poles. These two tubes are mounted over similar electro-magnets, the direction of discharge being in a line with the axis of the magnet. Numerous experiments, the details of which are given in the paper, show that the law is not the same at high as at low exhaustions. At high exhaustions the magnet causes the molecular rays to rotate in the same direction, whether they are coming towards the magnet or going from it; the direction of rotation being entirely governed by the magnetic pole presented to the stream. The north pole rotates the molecular discharge in a direct* sense, independent of the direction in which the induction current passes. The direction of rotation impressed on the molecules by a magnetic pole is opposite to the direction of the electric current circulating round the magnet. These results offer an additional proof that the stream of molecules driven from the negative pole in high vacua do not carry an electric current in the ordinary sense of the term.

The author, after giving details of experiments in which platinum and glass are fused in the focus of converging molecular rays projected from a concave pole, describes observations with the spectroscopic, which show that glass obstinately retains at even a red heat a compound of hydrogen—probably water—which is only driven completely off by actual fusion.

The permanent deadening of the phosphorescence of glass is shown by projecting the shadow of a metal cross on the end of a bulb for a considerable time. On suddenly removing the cross, its image remains visible, bright upon a dark ground.

One of the most striking of the phenomena attending this research is the remarkable power which the molecular rays in a high vacuum have of causing phosphorescence in bodies on which they fall. Substances known to be phosphorescent under ordinary circumstances shine with great splendour when subjected to the negative discharge in a high vacuum. Thus Becquerel's luminous sulphide of calcium has been found invaluable in this research for the preparation of phosphorescent screens whereon to trace the paths and trajectories of the molecules. It shines with a bright blue-violet light, and when on a surface of several square inches is sufficient to faintly light a room.

The only body which the author has yet met with which surpasses the luminous sulphides, both in brilliancy and variety of colour, is the diamond. Most diamonds from South Africa phosphoresce with a blue light. Diamonds from other localities shine with different colours, such as bright blue, apricot, pale blue, red, yellowish green, orange, and pale green. One very beautiful diamond in the author's collection gives almost as much light as a candle when phosphorescing in a good vacuum.

Next to the diamond, alumina and its compounds are

the most strikingly phosphorescent. The ruby glows with a rich full red, and it is of little consequence what degree of colour the stone possesses naturally, the colour of the phosphorescence is nearly the same in all cases; chemically prepared and strongly ignited alumina phosphoresces with as rich a red glow as the ruby. The phosphorescent glow does not therefore depend on the colouring-matter. E. Becquerel* has shown by experiments with his phosphoroscope that alumina and many of its compounds phosphoresce of a red colour after insolation.

Nothing can be more beautiful than the effect presented by a mass of rough rubies when glowing in a vacuum; they shine as if they were red-hot, and the illumination effect is almost equal to that of the diamond under similar circumstances.

Masses of artificial ruby in crystals, prepared by M. C. H. Feil, behave in the vacuum like the natural ruby.

In the spectroscopic the alumina glow shows one intense and sharp red line less refrangible than the line B, and a faint continuous spectrum ending at about B. The wavelength of the red line is 6895.

The paper concludes with some notes by Prof. Maske-lyne, on the connexion between molecular phosphorescence and crystalline structure.

The crystals experimented on have been the diamond, emerald, beryl, sapphire, ruby, quartz, phenakite, tinstone, hyacinth (zircon), tourmaline, andalusite, enstatite, minerals of the augite class, apatite, topaz, chrysoberyl, peridot, garnet, and boracite. Of these, the only crystals which give out light are the diamond, ruby, emerald, sapphire, tinstone, and hyacinth. The light from emerald is crimson, and is polarised, apparently completely, in a plane perpendicular to the axis. Sapphire gives out a bluish grey and a red light polarised in a plane perpendicular to the axis. The ruby light exhibits no marked distinction in the plane of its polarisation.

Among positive crystals tinstone glows with a fine yellow light, polarised in a plane parallel to the axis of the crystal. So far the experiments accord with the quicker vibrations being those called into play, and therefore is a negative crystal the extraordinary, and in a positive crystal the ordinary, is the ray evoked. Hyacinth, however, introduces a new phenomenon, being dichroic; the colours, in three different crystals, being pale pink and lavender-blue, pale blue and deep violet, and yellow and deep violet-blue, polarised in opposite planes.

The only conclusion arrived at is that the rays, whose direction of vibration corresponds to the direction of maximum optical elasticity in the crystal, are always originated where any light is given out. As yet, however, the induction on which so remarkable a principle is suggested cannot be considered sufficiently extended to justify that principle being accepted as other than probable.

VOLUMETRIC ESTIMATION OF SULPHURIC ACID, TANNIN, &c.

By ARTHUR G. HADDOCK, A.I.C.

In the volumetric estimation of sulphuric acid by a standard solution of baric chloride I have found that by the usual method of spotting on a black glass plate, it is often extremely difficult to tell exactly when the operation is finished. It is still more so in the estimation of tannin by standard gelatine solution, especially when the extract is highly coloured.

I find that by using a small glass mirror instead of the black plate this difficulty is entirely obviated, and that the point of complete precipitation is well and sharply defined—one drop of the standard solution in excess producing a very distinct reaction. It matters not how highly

* Like the hands of a watch.

* *Annales de Chimie et de Physique*, 3rd series, vol. lvi., p. 50.

coloured the solution may be, on the mirror it appears perfectly colourless.

With the mirror it is quite easy to detect the presence of lime by means of ammoniac oxalate in one drop of the Liverpool water, even in the cold. With baric chloride the sulphates make themselves very palpably visible; indeed, I think they might almost be estimated quantitatively in the undiluted water.

Royal Institution Laboratory, Liverpool,
April 3, 1879.

RELATIONS BETWEEN TEMPERATURE AND VOLUME IN THE GENERATION OF OZONE, WITH DESCRIPTION OF A NEW FORM OF OZONATOR.

By ALBERT R. LEEDS, Ph.D.

THE methods usually employed to generate ozone, by means of the slow oxidation of phosphorus partly immersed in water, are quite unsatisfactory. Thus Miller (*"Elements of Chemistry,"* 2nd ed., Part II., p. 23) directs that a stick of clean phosphorus, moistened with a few drops of water, should be placed in a bottle of atmospheric air. In an hour or two the production of ozone attains a maximum, when, if the phosphorus be not removed, the ozone disappears, owing to its combination with the phosphorus. Instead of a bottle a large glass balloon is preferably employed, which Arenat (*"Lehr. der Anorgan. Chem.,"* p. 416) directs to be covered with a glass plate, and allowed to remain before using for twelve hours. Gorup-Besanez (*"Anorgan. Chem.,"* p. 358) recommends, in addition to the foregoing, that the bottom should be maintained for several hours at a temperature of 16° to 20°. As means of studying, or even of exhibiting to a class, the properties of ozone, everyone who has used these and similar devices will probably have found them disappointing. At times a considerable evolution of ozone occurs, at others little or none. The causes of these variations will appear on examination of the experiments detailed later.

In a work published much earlier than the two last quoted, an apparatus is described and illustrated (*"Leçons de Chimie,"* A. Riche, tome i., p. 106), which was a step in the right direction. The balloon was provided with an entrance and exit tube, the latter extending nearly to the bottom, so that a slow continuous current of air might be drawn through by means of an aspirator. The ozonised air was washed in the usual manner, and the liquids to be subjected to the action of ozone were placed in a second wash-bottle. This contrivance was adopted, a large bell-jar turned upside down and covered with a glass plate being substituted for the wash-bottle when it was desired to ozonise dyed goods, flowers, and similar large objects. The apparatus was further improved by using a bell-jar in place of the balloon. The bell was set in a dish containing a number of sticks of phosphorus, the water with which they were partly covered acting as a seal. The disagreeable operation of occasionally cleansing the phosphorus by scraping was obviated by immersing them before using in a mixture of potassium bichromate solution and sulphuric acid.

These improvements, however, were of small importance compared with that effected by substituting the bichromate mixture for the water in the generator itself. The scanty fitful evolution of ozone was replaced by a copious and constant supply. The disk was now replaced by a jar capable of holding a considerable amount of the bichromate solution, and by permitting a considerable change of level in the liquid the air could either be drawn through by aspiration or forced through by pressure. Instead of placing the phosphorus on the bottom the sticks were now supported on a glass disk, which dropped into a cell connected with a paraffined iron rod sliding up

and down through the cork at top. In another generator the cell was replaced by a brass stirrup electroplated with gold; but this had to be abandoned, the solution speedily eating away the metal.

A difficulty now arose from the danger of inflammation, resulting from the great energy of oxidation. This danger seemed largely due to irregular melting down of the phosphorus, ridges being formed which protruded too far above the liquid. This unequal action also greatly diminished the amount of surface which could be safely exposed. To obviate these difficulties watch-glasses were placed in a shallow tin dish, filled with water, sufficient fragments of phosphorus placed in each, and the temperature raised until by melting the phosphorus a number of rounded cakes of uniform size had been made. Six of these could be placed upon the stage at one time, and the stage adjusted so that each cake exposed about 9 c.m. of surface area. As the convexity of the exposed portions was small, the liquid by surface action was constantly drawn on it in thin streams, and not only kept the phosphorus wet, but always clean and in condition of maximum chemical activity.

FIG. 1.

It was found, as will be seen by results stated below, that the air ozonised in one bell could have its ozone percentage notably increased, by passing through a second bell similar to the first, through a third, and so on. But as the manipulation of three, or even two, bells connected with glass tubes was troublesome, it became necessary to arrange suitable machinery. The bells were therefore cemented into heavy brass caps. Through these caps and the paraffined cork beneath, connecting tubes of heavy glass were passed, and a sliding glass rod which terminated below in a horizontal circle. The latter carried a disk of sheet lead, with a slot permitting its easy removal. The caps were then screwed fast to a board, having a suitable opening down its middle to permit of passage of tubes, &c., and this again fastened to chains by which it might be readily raised or lowered. The frame is made of such height that the jars may be easily slipped from under the bells when desirable. Thermometers are fastened into the side of each bell, their bulbs dipping just below the surface of the liquid.

It was evidently essential to convenient working of this apparatus to have a flexible connection between exit-tube and wash-bottle; but herein arose a very serious difficulty, india-rubber being destroyed. Through suggestion of Prof. Silliman, and by kindness of Mr. A. G. Day, the

* These ozonators are manufactured by S. H. Warkidge, successor to Walls and Co., Stevens Institute of Technology.

patentee, I became provided with a great variety of kerite tubing. Weighed samples of each kind were subjected to equal amounts of ozone for equal intervals, their changes and the products of decomposition noted. Without detailing these experiments, suffice it to say that the specimens which gained most in weight underwent greatest decomposition, some indeed crumbling to pieces, while others which gained none also did not change in appearance or physical characters. Of these the most satisfactory was selected, and from it as a guide Mr. Day manufactured the ozone-resisting kerite which is now used in connection with the oxonator.

The improvements effected in the ozone-generating apparatus were due, as has been said above, to a series of quantitative trials, the result of each set of experiments suggesting modifications in the next series. In the first place phosphorus was used with water alone, one bell only being employed. The ozonised air was washed, and afterwards drawn through two Peligot tubes containing a 10 per cent solution of potassium iodide. The second tube was added as a guard, but in practice is unnecessary, complete absorption occurring in the first. The liberated iodine, after acidifying with sulphuric (free from nitrous) acid, was titrated with sodium hyposulphite. In each experiment 9 litres of air were drawn over. It soon became evident that widely differing results were obtained at different temperatures, the percentage of ozone falling off with decrease of temperature to zero. Starting from this point it appeared to increase, according to some unknown law, to a maximum, and then decrease again with further increase of temperature, until the point of inflammation of the phosphorus was obtained. The volumetric ratio is given in terms of 0.005 V. p.c., taken at a convenient unit:—

I. Ozone from Phosphorus in Water,

Temp.	M. grm. per Litre, Air.	Wt. p.c.	C.c. per Litre.	Vol. Ratio.	Wt. p.c. of O.	V. p.c. of O.
20°	None	—	None	—	—	—
19.5	0.615	0.0478	0.290	5.8	0.2065	0.139
25.0	0.882	0.0682	0.413	8.3	0.2946	0.198
25.0	1.050	0.0812	0.494	9.9	0.3508	0.237
30.5	0.326	0.0252	0.153	3.1	0.1088	0.073

For convenience of comparison between these experiments and others, in which oxygen, not air, has been ozonised, columns 6 and 7 have been added—the former giving the percentage by weight of ozone in the oxygen passed over, disregarding the nitrogen; the latter, the percentage by volume. It will be seen that the maximum was attained at about 25°, when the air contained 1 m.grm. ozone in the litre, or about $\frac{1}{4}$ c.c. In the second series of experiments the water was replaced by a solution, containing to the litre of saturated solution potassium bichromate, 150 c.c. H_2SO_4 . In each experiment 8½ litres air were drawn over. The results were as follows:—

Temperature. Degrees.	Time. Minutes.	Hyposulphite. C.c.
7	—	0.40
13—14	70	4.25
20	56	6.77
21—22	—	7.10
24	60	8.35
30—31.5	60	7.13
31—32	60	7.18

From which it would appear that at a temperature of about 6° no ozone is given off, and from this point the percentage rises until the temperature attains about 24°, the percentage falling off quite evenly on both sides of the maximum. The maximum production was 1.86 m.grm. per litre air, corresponding to 0.87 c.c.

II. Ozone from Phosphorus in Bichromate. (One Bell Jar.)

Temp.	M. grm. per Litre, Air.	Wt. p.c.	C.c. per Litre.	Vol. Ratio.	Wt. p.c. of O.	V. p.c. of O.
7.0°	0.089	0.0069	0.042	0.8	0.0298	0.020
13.5	0.945	0.0730	0.441	8.8	0.3154	0.210
20.0	1.505	0.1163	0.705	14.1	0.5011	0.336
21.5	1.580	0.1221	0.741	14.8	0.5270	0.353
24.0	1.857	0.1438	0.870	17.4	0.6221	0.415
31.5	1.590	0.1229	0.745	14.9	0.5314	0.355

A third series of experiments was instituted to determine whether the air which had been ozonised in this manner could receive an increment of ozone by being again subjected to the influence of phosphorus in a second bell-jar. The liquid contained, to each litre of saturated solution of bichromate, 250 c.c. H_2SO_4 .

Temp.	Amount of Air.	Time.	Hyposulphite.
13°	2.0 litres	—	1.20 c.c.
19	2.0 "	12 minutes	2.00 "
21	2.0 "	—	2.10 "
23	3.0 "	—	3.00 "
24	3.5 "	20 minutes	4.00 "
24	2.0 "	—	2.60 "
27	2.0 "	—	2.25 "

III. Ozone from Phosphorus in Bichromate (Two Bells).

Temp.	M. grm. per Litre, Air.	Wt. p.c.	C.c. per Litre.	Vol. Ratio.	Wt. p.c. of O.	V. p.c. of O.
13°	1.134	0.0877	0.531	10.6	0.3789	0.255
19	1.890	0.1460	0.885	17.7	0.6307	0.425
21	1.985	0.1546	0.929	18.6	0.6696	0.446
23	1.890	0.1460	0.885	17.7	0.6307	0.425
24	2.155	0.1701	1.009	20.2	0.7344	0.489
24	2.457	0.1933	1.151	23.0	0.8338	0.552
27	2.127	0.1643	0.996	19.9	0.7098	0.478

It will be seen that the air ozonised in two bells likewise contains a maximum percentage at 24°, but this maximum is 25 per cent higher than the corresponding amount obtained with one bell; and in general the percentage obtained by two bells is 25 per cent greater than that with one bell at any given temperature.

Before proceeding further it appeared advisable to determine whether some other liquid might be substituted for the bichromate with advantage. Alkaline liquids seemed inapplicable, owing to the danger of formation of alkaline hyposulphites and the evolution of hydrogen phosphide. Of the acids sulphuric appeared the most suitable, although even this was attended with the disadvantage of the probable formation of some sulphurous anhydride at the same time. Mixtures of potassium permanganate and similar salts with dilute acid have not as yet been tried. The permanganate would have the disadvantage of being expensive, and even when sold as chemically pure is usually contaminated with much potassium chlorate. The results obtained with a bath containing 250 c.c. H_2SO_4 to the litre of water were as follows, 2 litres of air aspirated in each experiment, the interval varying from twelve to twenty-five minutes:—

Temperature 25°	Sodium hyposulphite 1.60 c.c.
" 26	" " 2.90 "
" 25	" " 1.06 "
" 26	" " 1.30 "
" 26	" " 1.35 "

These low results made it appear probable that the phosphorus had become oxidised. It was therefore allowed to stand for some time in the bichromate mixture, and the experiment repeated:—

Temperature 27° Sodium hyposulphite 1.70 c.c.,
Although even this amount was not so high as that previously obtained under similar circumstances, at the same

temperature, when the bichromate was employed, yet it confirmed the justness of the above supposition, and caused the use of the acid alone as a bath to be definitely abandoned. In the following table the trials are given in the order as made, with the view of showing the gradual deterioration. The abnormally high result obtained for the first 26° was due to the phosphorus having been kept for an unusual length of time in contact with the air in the bells, before aspiration was begun.

IV. *Ozone from Phosphorus in Sulphuric Acid.*
(Two Bells.)

Temp.	M.grms. per Litre Air.	Wt. p.c.	C.c. per Litre.	Vol. Ratio.	Wt. p.c. of O.	V. p.c. of O.
25°	1'512	0'1169	0'708	14'2	0'5011	0'340
26	2'741	0'2119	1'283	25'7	0'9154	0'616
25	1'002	0'0775	0'469	9'4	0'3347	0'225
26	1'229	0'0950	0'575	10'5	0'4104	0'276
26	1'275	0'0986	0'597	11'9	0'4259	0'287
27	1'607	0'1242	0'752	15'0	0'5365	0'361

Another related query was, whether so concentrated a bath was essential? To settle this point a solution was made containing, to each 1250 c.c. H₂O, 150 c.c. H₂SO₄ and 15 grms. K₂C₂O₇. The determinations were purposely made at about the maximum temperature:—

Temperature 26'5° Sodium hyposulphite 2'05 c.c.
" 26'5 " " 2'18 "

V. *Ozone from Phosphorus in Dilute Bichromate.*
(Two Bells.)

Temp.	M.grms. per Litre in Air.	Wt. p.c.	C.c. per Litre.	Vol. Ratio.	Wt. p.c. of O.	V. p.c. of O.
26'5°	1'890	0'1460	0'885	17'7	0'6307	0'425
26'5	2'060	0'1592	0'965	19'3	0'6868	0'461

These results, although inferior to those obtained with the more concentrated solution, were nevertheless so satis-

those read from the thermometers in the three bells, a reading being taken from each at the beginning, middle, and end of every experiment, and the average result stated. After the apparatus and bath had arrived at the temperature desired, the stages were raised by one motion of the crank to the height proper to expose a uniform surface of phosphorus; 8 litres of air aspirated, and then 1, 2, or more litres, the ozonised air in the latter case being titrated by solution of potassium iodide. All the figures obtained are given, although they are not so uniformly progressive as was hoped for—a result due, perhaps, in part to the difficulty of completely changing the atmosphere in three 6-litre bells by a slow current of air, without an expenditure of an amount of time which other duties would not permit.

Temperature.	Amount of Air.	Time.	Hyposulphite per Litre.

26'11	2 "	13 "	1'300 "
26'11	2 "	10 "	1'200 "

TEMPERATURES.

factory and constant that this mixture was adopted, and during the subsequent work the results arrived at on increasing the number of bells to two had been so gratifying that it was thought advisable to employ three, and to combine them in an arrangement which would permit them to be easily handled, the form finally adopted being that figured in the text. The temperatures given are

An inspection of the diagram shows that in every case the maximum evolution of ozone was at or near 24° C., or about 75° F. To obtain the best results in every case, therefore, a copper tank in which the jars are placed has been added to the apparatus as figured, so that by heating or cooling the water it contains the jars and apparatus can be always maintained at the proper temperature.

ON SOME NEW FORMS OF APPARATUS.

By M. BENJAMIN, Ph.B.

A NEW form of constant level water-bath has recently been devised, which is so simple that I will call public attention to it.

Much inconvenience has been experienced by chemists, who, having occasion to leave their laboratories for a while, on returning find that their baths have become dry, and possibly that the contents of the vessel over the bath may have been transferred to the floor by the increased heat, and the analysis is thus destroyed. The present ingenious device is so constructed as to obviate any such difficulty. Its mode of working is simple, and is as follows:—A large vessel (a common glass bottle will answer) is filled with water, and placed on a shelf or support above the bath. The water flows through a piece of rubber hose to the larger glass tube on the right of the

FIG. 1.

figure; running down this tube, it passes to the bath through the copper tube connected with the bottom of the bath. Within this glass tube is a smaller one, which is on an exact level with the top of the water-bath, through which any excess of water passes away and falls to the ground. The flow of water from the bottle can easily be regulated by means of an ordinary pinch-cock.

This water-bath is finding considerable use among students in the different laboratories, who are liable to be

FIG. 2.

called away to lectures, so that much of their time, otherwise lost, is saved by the use of this appliance.

The second engraving represents an improved form of burette clamp, which consists of two arms, one of which

is fixed, while the other is held in position by means of a joint, and is controlled by a spring, so that it acts as a lever, and by pressure it may be opened to any desired width. The end of the clamp is provided with rubber cushions, so as to hold a glass burette, or perhaps a funnel, which is placed between its arms. This clamp is made to slide on the upright of a common retort-stand.

New York, March 20, 1879.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, April 3, 1879.

Dr. WARREN DE LA RUE, President, in the Chair.

THE minutes of the Anniversary and last Ordinary Meetings were read and confirmed.

The following certificates were read for the first time:—
J. Fletcher, W. J. Bayne.

THE PRESIDENT then called on Dr. TILDEN to read a paper on "*Terpin and Terpinol*." This communication is a continuation of a previous paper (*Chem. Soc. Journ.*, June, 1878). *Crystallised Terpin*.—The liquid left after the deposition of the crystals has gone on some time contains terpinol and a nitrate, or the compound of terpinol with a nitrate, for after washing thoroughly with water and distilling in steam the yellowish oil obtained gives ammonia by the action of reducing agents, and when heated evolves nitrous fumes. Attempts to substitute sulphuric, acetic, and hydrochloric acids for nitric acid failed. The terpin hydrate, $C_{10}H_{18}O$ of Deville, seems to be nothing but terpinol. The author has obtained crystals of terpin hydrate from essence of lemon, identical in form with those obtained from American and French turpentine: he has not prepared similar crystals from the terpene of orange oil. *Terpinol*.—The author has taken the vapour density of this substance, and from it concludes that its formula is $C_{10}H_{18}O$. The alcoholic solution of terpinol dissolves 1 atom of sodium from sodium-amalgam, forming a white pasty substance, from which terpinol is regenerated by the action of water. No ether was obtained by the action of acetic acid. Hydrochloric acid gas is absorbed by terpinol, and the mixture at first turns purple, but finally is converted into a mass of colourless crystals ($C_{10}H_{18}Cl_2$), melting at 48° . From various considerations the author considers the character of terpinol to be that of an alcohol rather than that of a ketone like pinacolin. Sulphuric acid when heated with terpinol produced dehydration with partial polymerisation of the resulting hydrocarbon, which is apparently identical with terpinene. When, however, terpinol is mixed gradually with nearly unequal volume of sulphuric acid, diluted with half its bulk of water, but little heat is evolved, and no separation of the liquids takes place: on adding 3 or 4 volumes of water the whole solidifies in a few minutes into a crystallised mass of terpin, mixed with only a small quantity of liquid hydrocarbon. Oil of lemon, cajuput oil, oil of coriander and citronella apparently contain bodies either identical with terpinol or mere physical modifications of that substance. Resin spirit does not apparently contain terpinol.

Dr. ARMSTRONG thought that the reactions of terpinol pointed to a resemblance in constitution to pinacolin rather than to an alcohol, and suggested that these compounds should have a rational name expressing to some extent their constitution.

Dr. TILDEN, in reply, said that he should be reluctant to change the name until homologues were discovered, as it had been suggested by Berzelius: on the whole he adhered to his statement in the paper, that the behaviour of terpinol resembled that of a secondary or tertiary alcohol.

Mr. G. ATTWOOD then read a paper "*On a Gold Nugget from South America.*" In the State of Guayana, Venezuela, a large area of alluvial soil has lately been found to contain gold, and nuggets up to 25 ounces have been discovered within 3 feet of the surface. Numerous gold-bearing quartz veins are found in the neighbouring hills. Quite one-half of these nuggets are covered with a dark brown substance, resembling a silicate of iron. Such a nugget was treated with hydrochloric acid (its weight diminished, after treatment with HCl and NaO, from 304.7 grains to 284.33 grains). The solution contained—Silica, 0.12 gr.; ferric oxide, 8.88; lime, 0.15; magnesia, 0.08. The nugget was then treated with caustic soda, and again with HCl. The solution contained—Silica, 4.66 gr.; ferric oxide, 4.60; lime, 0.21. During this process much gold in a finely divided state became detached, and after the treatment the nugget was partly covered with a coating of finely divided gold, of a dull colour. The nugget contained 94.54 per cent of gold. The gold from the quartz veins contains 87.9 per cent gold. From these experiments the author concludes that gold nuggets gradually increase in size, owing to the accumulation of fresh particles of finely precipitated gold. Specimens of these nuggets showing the dark glazed coating were exhibited, including one weighing over 14 ounces.

Mr. W. W. FISHER then communicated a paper "*On Lead Tetrachloride.*" The existence of this compound has been for many years assumed on theoretical grounds, but direct experimental evidence has not been hitherto obtained to establish its composition. The author has therefore followed a plan similar to that already used by him to prove the existence of manganese tetrachloride. Lead dioxide dissolves in moderately strong hydrochloric acid, forming a yellow solution smelling strongly of chlorine. This yellow solution gives a precipitate of brown hydrated peroxide of lead when treated with solutions of the fixed alkalis or alkaline carbonate, &c. The addition of water causes a similar precipitation if an excess of hydrochloric acid be avoided, and the liquid carefully saturated with the dioxide. The author gives his method of analysis: he concludes that the yellow solution contains a compound of lead with chlorine, containing 1 atom of lead to 4 of chlorine. If red-lead be substituted for the lead dioxide a similar yellow solution is obtained; it can also be prepared by the action of chlorine on lead chloride suspended in dilute hydrochloric acid or solution of a chloride. If water alone be used, lead dioxide is deposited simultaneously with the formation of the yellow solution. From his experiments the author concludes that lead tetrachloride is unstable in the presence of water alone, but may exist as a double salt in the presence of other chlorides. In conclusion, the author suggests the use of chlorine or bromine in the presence of sodium acetate as a means of quantitatively determining lead by precipitation, as peroxide increases where the use of sulphuric acid is unadvisable, and gives results obtained. By thus precipitating a solution of lead acetate (in the presence of sodium acetate) as peroxide, igniting the latter to protoxide, and weighing 54.71 and 54.67 per cent Pb were obtained, theory indicating 54.67.

The PRESIDENT remarked on the importance of the suggestion as to the use of Br and Cl for precipitating lead from solution, as in many cases sulphuric acid did not completely precipitate lead.

After a short discussion, in which Drs. Wright and Tilden and Messrs. Hartley and Nelson took part, Mr. Fisher replied.

The SECRETARY then read a short note by Messrs. DALZ and SCHORLEMMER, "*On the Transformation of Aurin into Trimethyl-pararosanilin.*" This transformation was effected by the action of an aqueous solution of methylamin, at 125°, on aurin, a purple colour being formed possessing all the properties of a trimethyl-roosanilin. Intermediate compounds, soluble in alkalis, were simultaneously produced, and are at present under investigation.

The next paper was "*On the Solution of Aluminium Hydrate by Ammonia, and a Physical Isomeride of Alumina,*" by C. F. CROSS. The author has made quantitative experiments with solutions of ammonia of various strengths. His results indicate that ammonia dissolves to a certain extent the hydrated oxide at the moment of precipitation: the quantity dissolved bears no relation to the strength of the ammonia, but is considerably lessened by the presence of ammoniacal salts. The author has also examined the precipitate obtained by boiling the ammoniacal solution of the oxide: it is granular, is slowly dissolved by boiling hydrochloric acid; dried at 100° it is an opaque white powder; on igniting it undergoes no apparent change, but in the anhydrous condition it is extremely hygroscopic, absorbing 35.70 of water; its composition is Al_2O_3 .

The last communication was entitled "*Researches in Dyeing (Part II., Note on the Emission of Colouring-Matter),*" by Dr. MILLS and Mr. CAMPBELL. The experiments were made as described in Part I. (*Chem. Soc. Journ.*, 1879). The colour selected was well-crystallised Nicholson's blue. The vats contained 0.2780 grm. of pure silk ribbon, and 0.0100 grm. of blue in 400 c.c. of water; one contained in addition 1 grm. of HCl, and a third 1 grm. of NaCl. The most interesting result obtained by the authors is that the energy of combination between silk and the blue, when water or potassic chloride is used, is over-developed at first, and the excess of colouring-matter so taken up is gradually emitted by the silk during the third and fourth days; the addition of sodic chloride completely prevents this result. The authors also affirm that a real and uniform dyeing effect can always be obtained with silk and Nicholson's blue, the heat and souring used by dyers being unadvisable. The authors recommend the addition of common salt to the vat.

The PRESIDENT, in adjourning the meeting to April 17th, said that as so many candidates were awaiting election he hoped that Fellows of the Society would make every effort to be present on that date, so that a ballot might be taken.

The following papers were announced:—"On the Determination of Tartaric Acid in Lees and Inferior Argol, with some Remarks upon Filtration and Precipitation," by B. J. Grosjean. "On Conditions affecting the Equilibrium of certain Chemical Systems," by M. M. P. Muir.

CORRESPONDENCE.

ARSENICAL WALL PAPERS.

To the Editor of the Chemical News.

SIR,—I have read and heard of a good many cases of reputed poisoning from arsenical wall papers, but have never till now met with a case myself. It would seem that some people are more susceptible than others. I have slept for months in a room the paper of which contained an enormous quantity of As without experiencing any ill-effects therefrom, although I could easily rub the colour off with my finger—but to my case.

A lady in this town complained of a peculiar feeling of constriction in her nose, accompanied by a "nasty smell," nausea, and loss of appetite, and was unable to discover the cause. The symptoms had been felt since sleeping in a certain room, which she had done for two months. Somebody, I believe, suggested arsenical paper. I examined the paper and found a very large quantity of As, more than I have ever found in any paper before. H_2S gave at once a brilliant orange precipitate. Under the circumstances I could do no less than recommend that the paper should be removed, but I wanted her to try the experiment of sleeping in another room for a time to see if the symptoms disappeared, and then return again to see

if they came back, as I thought they might possibly be due to other causes. However, she would not.

I analysed the paper and found 0.35 grm. As_2O_3 per square foot, but that will scarcely represent the total amount because the paper was wetted in order to remove it, and the greater proportion of the bright green flowers washed off. There was very little copper present. I may mention that the lady's husband was not affected in the slightest degree.—I am, &c.,

A. PERCY SMITH.

Temple Observatory, Rugby
April 3, 1879.

PURE CAUSTIC POTASSA.

To the Editor of the Chemical News.

SIR,—With reference to the methods for the manufacture of potassium iodide as described by E. Schering (CHEMICAL NEWS, vol. xxxix., p. 118), he very justly ascribes the chief objection to the process in which iodine is introduced into caustic potassa and fused with carbon, to be the difficulty of obtaining caustic potassa of sufficient purity, the presence of sulphate and soda salts being most objectionable. A caustic potash practically free from these and other impurities has hitherto been unobtainable at a commercial price, and the introduction of such an article suitable for the manufacture of potassium iodide and other industries has long been a desideratum in the chemical world. This difficulty has but lately been removed by the manufacture on the large scale of caustic potash at St. Helens, by the Greenbank Alkali Works Company, of a purity which leaves nothing to be desired, a sample which recently came under my notice possessing total impurities under one per cent, of which only 0.2 was in the form of sodium hydrate. The removal of the difficulty of obtaining a caustic potash of the necessary purity being removed, the process as described above for the manufacture of potassium iodide appears to me to be the simplest and best, and having at one time been engaged in the manufacture of the article, I can therefore speak with some experience.—I am, &c.,

A. R. GARRICK, Ph.D., F.I.C.

St. Helens, April 3, 1879.

OBITUARY.

J. M. MERRICK.

WE regret to announce the death of Mr. J. M. Merrick, of Boston, U.S., who was an occasional contributor to our columns. Mr. Merrick died on the 25th day of February last, at the early age of forty-one years. In his professional life he had gained the respect of all who knew him by his uprightness of character and the ready courtesy with which he imparted his knowledge to other members of the chemical profession.

An Electric Blowpipe.—M. Jamin.—The author remarks that the electric arc which plays between two carbon conductors is a true current. If submitted to the influence of a neighbouring current, of a solenoid, or of a magnet, it experiences an action regulated by the laws of Ampère, identical with that experienced by any metallic conductor put in its place, but as its mass is exceedingly trifling its speed is considerable. The author takes advantage of this fact to submit small quantities of matter to an intense heat. By causing the arc to be driven upon lime, magnesia, or zirconia the light is directed downwards, and its intensity is increased at least three-fold.—*Comptes Rendus*.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 11, March 17, 1879.

New Experiments on Telephones without Diaphragm.—M. Ader.—The author's experiments demonstrate the truth of the opinion of M. du Moncel concerning the origin of the sounds reproduced in the telephone.

New Combinations of Hydrochloric Acid with Ammonia.—L. Troost.—The author remarks that hydrochloric acid and ammonia have hitherto been obtained only in the proportions which form sal-ammoniac, analogous to common salt. No hydrochlorate of this chloride has yet been discovered, nor an ammoniac hydrochlorate with excess of base. He has discovered a great number of curious compounds formed by dry ammonia with hydrochloric acid, hydrosulphuric acid, and other acids, both mineral and organic. He takes ammoniacal gas absolutely dry and free from every trace of compound ammonias, saturates it with pure dry hydrochloric acid, and submits the sal-ammoniac thus obtained and distilled in a close vessel to the action of a large excess of gaseous ammonia, refrigerating to different degrees. He thus obtains two well-defined compounds, characterised by their point of fusion, their crystalline structure, and their tension of dissociation. The former of these, tetra-ammoniac hydrochlorate, HCl_4NH_3 , melts at $+7^\circ$, and its crystals depolarise light powerfully. The other compound, hepta-ammoniac hydrochlorate, HCl_7NH_3 , melts at -18° .

Combinations of Hydrogen Phosphide with Cuprous Chloride and its Determination in Gaseous Mixtures.—J. Riban.—The compound $\text{Cu}_2\text{Cl}_2 \cdot 2\text{PH}_3$, chloride of cuproso-diphosphonium, is obtained by slowly passing hydrogen phosphide into a solution of cuprous chloride, refrigerated by means of ice. Hydrogen phosphide present in gaseous mixtures may be determined by agitation along with a solution of cuprous chloride in hydrochloric acid.

The Crystalline Forms of the Compounds of the Stanmethylys and of their Homologues.—M. Hiortolahl.—Not susceptible of useful abstraction.

New Method of Treating Iron and Copper Pyrites in the Dry Way.—L. Simonin.—An account of J. Hollway's experiments.

The State in which the Precious Metals are found in some of their Combinations, in Ores, Rocks, and Artificial Products.—E. Cumenge and Edmond Fuchs.—The authors find that in certain pyrites gold is found not native but in combination with antimony, and is incapable of being taken up by mercury.

Constitution of Coal.—E. Guignet.—The author on treating dry powdered coal with phenol has extracted as much as 4 per cent of a brown matter. If coal in very fine powder is treated in a cohobator with nitric acid, oxalic acid and trinitro-resorcin are distinctly recognisable among the products. Resorcin was not detected in the coal.

Alcoholic Fermentation.—P. Schützenberger and A. Destrem.—If yeast is placed in such conditions as to prevent its development and multiplication it nevertheless preserves its power of decomposing sugar, and if it acts upon sugar it de-assimilates more nitrogen than if preserved in presence of water without sugar and oxygen.

Determination of Glucose in Blood.—P. Cazeneuve.—The author criticises the method of determination followed by C. Bernard as the progress of the reduction of

the cupro-potassic liquid is often uncertain when the reaction approaches its limit. It is also reduced by other principles present in the blood. The author thinks that glycaemia should be studied anew when a more accurate analytical procedure has been devised.

Derivatives of Normal Methyl-oxyl-butyric Acid.—E. Du villier.—An account of the methyl-oxyl-butyric acid of ethyl and methyl and of methyl-oxyl-butyramid.

Nature of the Albumen of Hydrocele.—M. Bechamp.—Three distinct albumens are present different from blood albumen.

Modifications of the Physical Properties of Starch.—F. Musculus.—Amylaceous matter may exist either in the colloid or the crystalloid state. When crystalline it is soluble even in cold water.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin,
No. 15, 1879.

The Chloranilins.—F. Beilstein and A. Kurbatow.—An account of the di-, tri-, and tetra-chloranilins. The authors propose to found the nomenclature of these compounds on the relative position of the chlorine atoms.

Para-di-propyl-benzol and Certain of its Derivatives.—H. Körner.—An account of sulpho-para-di-propyl-benzolic acid with its lead, barium, and calcium salts; of dinitro-para-di-propyl-benzol, and of propyl-benzoic acid.

Determination of Vapour-Densities.—V. Meyer.—Not intelligible without the accompanying engraving.

Occurrence of Furfural in Commercial Glacial Acetic Acid.—V. Meyer.—The author has found that glacial acetic acid, represented as containing from 99 to 100 per cent of real acid and apparently of unexceptional quality, assumed a splendid red colour on contact with aniline, but lost this property on distillation with chromic acid. This colouration was due to the presence of furfural of which 0.108 gm. was found per litre of acid.

Variability of the Colouring-matter of Red Wine.—J. Erdmann.—The author traces decided differences in the behaviour of genuine wine of one and the same growth according to its age.

Spectroscopic Researches on the Constitution of Solutions.—H. Burger.—In this paper the author communicates merely his methods of observation.

Malabar Gum Kino and a New Compound, Kinoin.—C. Etti.—The author added kino to twice its weight of boiling dilute hydrochloric acid (1 : 5). Kino-red separates out as a soft mass, which slowly hardens on cooling, while the kinoin remains in solution, contaminated with a little kino-red. When purified it crystallises in colourless well-formed prisms, sparingly soluble in cold water, readily at a boil, and very easily in alcohol of every concentration. The solution is not precipitated by glue and is coloured red by ferric chloride. The composition of kinoin is $C_{14}H_{12}O_6$.

Mono- and Diphenyl-arsenic Compounds.—W. La Coste and A. Michælis.—The readiness with which phosphorphenyl chloride can be obtained from phosphorus chloride and benzol induced the authors to examine if this reaction could not be generalised so as to serve for the preparation of the corresponding arsenical compounds.

Tri-phenyl-arsin and its Derivatives.—W. La Coste and A. Michælis.

Mono-tolyl-arsenic Compounds.—W. La Coste and A. Michælis.—These two papers may be regarded as continuations of the foregoing.

Schizomycetic Fermentations.—An examination of the fermentations of erythrite, glycerin, mannite, citrate of lime, malate of lime, &c., infected with cow-dung, infusion of hay, and certain varieties of purulent matter.

Thioglycolic and Thiodiglycolic Ethers.—C. Böttger.—The author has obtained these products by the

action of sulphuretted hydrogen upon glyoxylic acid in presence of silver oxide.

Mineral Waters near Buda Pest.—M. Ballo.—This memoir may possibly be of medical interest.

Studies in the Naphthalin Series.—Raphael Meldola.—The object of this communication is to throw light upon the constitution of the naphthalin derivatives. The author gives an account of dibrom-acet-naphthalide.

Sulph-etheric Acids of the Phenols.—E. Baumann.—In describing the sulpho-cresolic acids, the author remarks that the sulpho-para-cresolate of potassium is a constant ingredient in the urine of horses and probably also of other mammals.

Bromo-acetic Ethyl-ether.—F. Kessel.—A lengthy memoir, not adapted for abstraction.

Action of Dry Ammonium Sulphate upon Dry Barium-ethyl Sulphate in Presence of Baryta.—H. Köhler.—The author obtains ethyl-amin, but in small quantity only.

Decomposition of Ethyl-sulphates by Gaseous Hydrochloric Acid.—H. Köhler.—The products formed are free sulphuric acid, barium sulphate, and chlor-ethyl.

Tropæolin as an Alkalimetric Indicator.—Dr. Lunge.—The author confirms the statements of Miller concerning the use of tropæolin OO for the titration of sodium carbonate, and for determining the free acid in alumina. Not merely the carbonate but sodium sulphide (in the crystalline state) may be accurately titrated in the cold with sulphuric acid, using tropæolin as indicator. On the slightest excess of acid appearing, the yellowish colour changes at once to a magenta and then to orange, which after a few seconds disappears entirely. Tropæolin OOO undergoes the reversed play of colour, being yellow in acid solution, but turning to a magenta-red in alkalis.

Reimann's Färber Zeitung,
No. 11, 1879.

Two new green dyes have been introduced into practical use; the *Vert acide* of A. Poirrier, of Paris, and the Victoria green of the Baden Aniline Company. The price of the latter is only 16s. per kilo.

The red azo-colouring-matters are fast superseding cochineal in the flannel dye works of Saxony. They have the advantage of not being injured by washing.

No. 12, 1879.

Washing Wool with Ether and Alcohol.—The result of the experiments made at Ensival, near Verviers, is stated as follows:—70,000 kilos. wool and 16,000 kilos. yarn were extracted. The former yielded 15,800 kilos. of oil, or 22.6 per cent, and the latter 2400 kilos., or 15 per cent. The oil was sold at 39 to 40 francs per 100 kilos. The loss of ether amounted to 4.9 kilos. per 100 kilos. of wool treated.

No. 23, 1879.

It appears that milk is dyed in the cows. If fed with *Anchusa tinctoria* they yield a blueish milk, if with *Rheum palmatum* a yellowish, and if with madder or bed-straw (*Galium*) a reddish.

Justus Liebig's Annalen der Chemie,
Band 196, Heft 1.

Constitution of Phenanthren.—Gustav Schultz.—The author infers that phenanthren-quinon and consequently phenanthren are to be regarded as diortho-compounds.

On Phenanthren-quinon.—R. Anschütz and Gustav Schultz.—An account of the preparation of this compound and its behaviour with aqueous alkalis and lime, with alcoholic potassa, and alcoholic ammonia.

Researches on Hydrogen Peroxide.—E. Schöne.—The author has investigated the behaviour of hydric peroxide with the oxygen compounds of thallium. He finds that thallium paper is turned brown by the vapour of hydric peroxide in consequence of the formation of thallic oxide. Hence the browning of thallium test-papers on exposure to atmospheric air is by no means a proof of the presence of ozone.

On Aurin.—R. S. Dale and C. Schorlemmer.—The authors describe their conversion of "red corallin" or "peonin" into rosanilin. They have further examined ammonia-aurin, tetrabrom-aurin—which latter compound is very similar to tetrabrom-rosolic acid, soluble in alkalies with a fine violet colour, whilst its acidified solutions dye silk and wool a dark violet. They have further investigated the action of acetyl chloride and anhydrous acetic acid upon aurin, the compounds of aurin with acids. The compounds of aurin with acids are red like the aurin itself, whilst those with the acid sulphites of the alkali metals and with anhydrous acetic acid are colourless like leukaurin. The homologue of aurin rosolic acid likewise forms with acids well crystallised compounds, and as a powerful base. Hence it should not be considered as an acid, and might be more appropriately named rosaurin.

On Pyruvic Acid.—Dr. C. Böttger.—The author shows that the quantity of pyruvic acid obtained from glyceric acid is so trifling that it is inadmissible to make use of this manner of formation for the deduction of a constitutional formula for the latter acid. The demonstrated identity of the sulpho-lactic acid from pyruvic acid and from α -chlor-propionic acid is evidence for the ketonic character of pyruvic acid.

Communications from the Chemical Laboratory of the University of Kasan.—These consist of papers on Allyl-dipropyl-carbinol, by P. and A. Saytzeff; and on Allyl-di-ethyl-carbinol, by A. Schirokoff and A. Saytzeff.

Action of Tertiary Butyl-iodide on Isobutylene in Presence of Metallic Oxides.—J. Lermontoff.—Not susceptible of useful abstraction.

Tetra-methyl-ethylen and its Derivatives, and the Chemical Structure of Pinakon.—D. Pawlow.—Not suitable for abstraction.

La Lancette Belge.

M. Schnetzer, Professor at Lausanne, finds that in presence of borax all the colouring-matters of plants except chlorophyll are diffused, so that the plant becomes colourless; red flowers, for instance, become green.

Mr. Edison is said to have invented an ink which gives raised characters upon paper, capable of being read by the blind by touch.

MEETINGS FOR THE WEEK.

TUESDAY, 15th.—Civil Engineers, 8.
WEDNESDAY, 16th.—Meteorological, 7.
THURSDAY, 17th.—Chemical, 8. "On the Determination of Tartaric Acid in Lees and Inferior Argol, with some Remarks upon Filtration and Precipitation," by B. J. Grosjean. "On Conditions Affecting the Equilibrium of Certain Chemical Systems," by M. M. P. Muir.
Zoological, 4.

ERRATA.—P. 97, col. 1, line 6 from top, for 25 to 30 per cent read 0.25 to 0.30 per cent. Line 14 from top read 0.25 to 0.26 per cent.

SOUTH LONDON SCHOOL OF PHARMACY. TO STUDENTS.

DR. MUTER will commence a course of Twelve Lectures and four tutorial evenings, on the Elements of Light, Heat, and Electricity, fully illustrated by experiments, on April 22nd, 1879, at 7 p.m. Tickets £2 2s. each, to be had of W. Baxter, Secretary, at the Office of the School, Kennington Cross, S.E.

THE MONTHLY JOURNAL OF SCIENCE AND ANNALS OF BIOLOGY, ASTRONOMY, GEOLOGY, INDUSTRIAL ARTS MANUFACTURES, AND TECHNOLOGY.

Edited by WILLIAM CROOKES F.R.S., &c.

The third number of the Monthly Series (April, 1879) is Now Ready.

Price One Shilling and Sixpence.

CONTENTS.

- I. Is Nature Perfect?
 - II. Thoughts on Our Conceptions of Physical Law. By Prof Francis E. Nipher.
 - III. The Old Stannaries of the West of England. By James Quick.

**EXPERIMENTAL RESEARCHES IN
PURE, APPLIED, AND PHYSICAL CHEMISTRY.** By E. FRANKLAND, Ph.D. (Marburg), D.C.L., F.R.S., Professor of Chemistry in the Royal School of Mines, &c.

ALSO BY PROFESSOR FRANKLAND,

**LECTURE NOTES FOR CHEMICAL
STUDENTS.** Post 8vo., Fifth Thousand of Vol. I. (Inorganic) 4s. Second Edition of Vol. II. (Organic), 5s.

JOHN VAN VOORST, 1, Paternoster Row.

Chemist (age 21), who has studied for five years in Scotch and German Laboratories, and who has had considerable experience in analysis and research, desires Engagement as Assistant Chemist in a College or Works. Good references.—Apply, J. T., 26, Royal Exchange Square, Glasgow.

There is an excellent opening for a Youth, with a knowledge of Chemistry, in a Laboratory, where he will have the advantage of improving himself and gaining experience in commercial analyses.—Address, Beta, CHEMICAL NEWS OFFICE, Boy Court, Ludgate Hill, London, E.C.

The Runcorn Soap and Alkali Co., Limited, Runcorn, are in want of a Youth in the Laboratory as an Apprentice for three or four years.—Apply by letter only to the Runcorn Soap and Alkali Co., Limited, Runcorn.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy Manure; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw, near Clayton, Manchester.

TO CHEMISTS, &c.

Shop and Excellent Dwelling-house at Chislehurst (Lower Camden, close to the Railway Station), TO BE LET ON LEASE, without premium. It occupies a prominent position, is certain to command a good family business, and is well adapted for the district Post and Telegraph Office, which is much needed. A low rental would be accepted for the first three years.—Apply at Mr. David J. Chattell's Estate Agency Office, which adjoin.

TO BE LET.—An Eligible Dwelling-House, with Laboratory fitted complete, suitable either for a Chemist in analytical practice or for classes in practical chemistry. Possibly a small income. Rent very moderate.—For price of fixtures and fittings and further particulars apply to E. and S. Smith, Auctioneers and Agents, 22, Southampton Buildings, Chancery Lane, W.C.

MR. COX, VALUER OF CHEMICAL PLANT, offers his services on the usual terms. Twenty years' experience. Estimates for all description of plant, plans, &c.—Glenmore House, New Charlton London, S.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1012.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.

By Professor ABEL, C.B., F.R.S.

AMONG the many explosive preparations which have during the last thirty years been proposed as substitutes for gunpowder, on account of greater violence and other special merits claimed for them, not one has yet competed with it successfully as a propelling agent, nor even as a safe and sufficiently reliable explosive agent for use in shells; for industrial applications and for very important military or naval uses, dependent upon the destructive effects of explosives, it has had, however, to give place, to a very important extent, and in some instances altogether, to preparations of gun-cotton and nitro-glycerin.

But there appeared little prospect that either gun-cotton or nitro-glycerin, whether used in their most simple conditions or in the forms of various preparations, would assume positions of practical importance as explosive agents of reliable, and therefore uniformly efficient, character, until the system of developing their explosive force through the agency of a detonation, instead of through the simple agency of heat, was elaborated.

Before the first step in this important advance in the application of explosive agents was made by Alfred Nobel, about twelve years ago, the very variable behaviour of such substances as gun-cotton and nitro-glycerin, when exposed to the heat necessary for their ignition under comparatively slight modifications of attendant conditions (*e.g.*, as regards the completeness and strength of confinement or the position of the source of heat with reference to the main mass of the material to be exploded) rendered them uncertain in their action, and at any rate, only applicable under circumstances which confined their usefulness within narrow limits. The employment by Nobel of an initiative detonation, produced by the ignition of small quantities of mercuric fulminate or other powerful detonating substances, strongly confined, for developing the violent explosion, or detonation, of nitro-glycerin, opened a new field for the study of explosive substances, and the first practical fruit was the successful application of plastic preparations of nitro-glycerin and of compact forms of compressed gun-cotton, with simplicity and certainty, to the production of destructive effects much more considerable than could be accomplished through the agency of much larger amounts of gunpowder, applied under the most favourable conditions. Whereas very strong confinement has been essential for the complete explosion of these substances, so long as the only known means of bringing about their explosion consisted simply of the application of fire or sufficient heat, no confinement whatever is needed for the development, with certainty, of a decidedly more violent explosive action than they are capable of exerting when thus applied, if they are detonated by submitting some small portion of the mass to the blow or concussion developed by a sharp detonation, such as is produced by the ignition of a small quantity of strongly confined mercuric fulminate.

The conditions essential to the development of detonation in masses of nitro-glycerin and gun-cotton, or preparations of them, and the relations to and behaviour towards each other of these and other explosive bodies, in their character or functions as detonating agents, has been

made the subject of study by the lecturer during the last ten years, and some of the earlier results published by him in connection with this subject also led to the pursuit of experimental inquiries of analogous character by Champion and Pellet and others.

Some of the chief results attained by Mr. Abel's experiments may be briefly summarised.

It was found that the susceptibility to detonation, as distinguished from explosion, through the agency of an initiative detonation, is not confined to gun-cotton, nitro-glycerin, and preparations containing those substances, but that it is shared, though in very different degrees, by all explosive compounds and mixtures.

It was demonstrated that the detonation of nitro-glycerin and other bodies, through the agency of an initiative detonation, is not ascribable simply to the direct operation of the heat developed by the chemical changes of the charge of detonating material, and that the remarkable property possessed by the sudden explosion of small quantities of certain bodies (the mercuric and silver fulminates) to accomplish the detonation of nitro-glycerin and gun-cotton, is accounted for satisfactorily by the mechanical force thus suddenly brought to bear upon some part of the mass operated upon. Most generally, therefore, the degree of facility with which the detonation of a substance will develop similar change in a neighbouring explosive substance, may be regarded as proportionate to the amount of force developed *within the shortest period of time* by that detonation, the latter being in fact analogous in its operation to that of a blow from a hammer or of the impact of a projectile.

Thus, explosive substances which are inferior to mercuric fulminate in the suddenness, and the consequent momentary violence, of their detonation, cannot be relied upon to effect the detonation of gun-cotton, even when used in comparatively considerable quantities. Percussion cap composition, for example, which is a mixture of fulminate with potassium chlorate, and is therefore much less rapid in its action than the pure fulminate, must be used in comparatively large quantities to accomplish the detonation of gun-cotton.

The essential difference between an explosion and what we now distinguish as a detonation lies in the comparative suddenness of the transformation of the solid or liquid explosive substance into gas and vapour.

The gradual nature of the explosion of gunpowder is illustrated, in its extreme, by burning a train of powder in the open air; the rapidity and consequent violence of the explosion is increased in proportion to the degree of confinement of the exploding charge, or to the resistance to the escape or expansion of the gases generated upon the first ignition of the confined substance. In proportion as the pressure is increased under which the progressive transformation of the explosive takes place, the rapidity with which its particles are successively subjected to the action of heat is increased.

In the case of a very much more sensitive and rapidly explosive substance than gunpowder, such as mercuric fulminate, the increase in the rapidity of its transformation, by strong confinement, is so great that the explosion assumes the character of a detonation in regard to suddenness and consequent destructive effect. A still more sensitive and rapidly explosive material (such as the silver fulminate and iodide of nitrogen) produces when exploded in open air effects akin to those of detonation; yet even with these bodies confinement operates in increasing the rapidity of the explosive to suddenness, and consequently in developing a more purely detonative action. Thus, the violence of explosion of silver fulminate is decidedly increased by confining the substance in a stout metal case, and the enclosure of iodide of nitrogen in a shell of plaster of Paris has a similar effect. With chloride of nitrogen, the suddenness of detonation, and consequently the violence of action, was found to be very greatly increased even by confining the liquid beneath a thin layer of water.

Detonation, developed in some portion of a mass, is

* Abstract of a Paper read before the Royal Institution of Great Britain, Friday, March 27, 1879.

transmitted with a velocity approaching instantaneousness throughout any quantity, and even if the material is laid out in the open air in long trains composed of small masses. The velocity with which detonation travels along trains thirty or forty feet in length, composed of distinct masses of gun-cotton and of dynamite, has been determined by means of Noble's chronoscope, and was found to range from 17,000 to 24,000 feet per second. Even when trains of these explosive agents were laid out with intervening spaces of half an inch between the individual masses composing the trains, detonation was still transmitted along the separated masses with great though diminished velocity.

The suddenness with which detonation takes place has been applied as a very simple means of breaking up shells into small fragments, and scattering these with considerable violence, with employment of very small charges of explosive agent. Thus, by filling a 16-pr. common shell completely with water, and inserting a charge of $\frac{1}{4}$ oz. of gun-cotton fitted to a detonating fuze, the shell being thoroughly closed by means of a screw-plug, the force developed by the detonation of the small charge of gun-cotton is transmitted instantaneously in all directions by the water, and the shell is thus broken up into a number of fragments averaging fourteen times the number produced by bursting a shell of the same size by means of the full amount of powder which it will contain (13 ozs.). Employing 1 oz. of powder in place of $\frac{1}{4}$ oz. of gun-cotton in the shell filled with water, the comparatively very gradual explosion of the powder charge is rendered evident by the result, the shell being broken up into less than twenty fragments by the shock produced by the first ignition of the charge, transmitted by the water. In this case the shell is broken up by the minimum amount of force necessary for the purpose, before the explosive force of the powder charge is properly developed. Extensive comparative experiments, carried on not long since by the Royal Artillery, at Okehampton, demonstrated that this simple expedient of filling common shells with water and attaching a small charge of gun-cotton with its detonator to the fuze usually employed, allowed of the application as efficient substitutes for the comparatively complicated and costly shrapnel and segment shells.

Another illustration of the sharpness of action developed by detonation as compared with explosion, consequent upon the almost instantaneous character of the metamorphosis which the explosive agent undergoes in the cases of detonation, is afforded by a method which the lecturer applied some years since for comparing the violence of action of charges of gun-cotton and of dynamite arranged in different ways. The charges (5 lbs.) to be detonated were freely suspended over the centres of plates of very soft steel of the best quality, which rested upon the flat face of a massive block or anvil of iron, having a large central circular cavity. The distance between the upper surface of the plate and the charge suspended over it was 4 feet. The sharp blow delivered upon the plate by the air suddenly projected against it by the force of the detonation when the charge was fired forced the metal down into the cavity of the anvil, producing cup-shaped indentations, the dimensions of which afforded means of comparing the violence of the detonation. A much larger charge of powder exploded in actual contact with the plate would produce no alteration of form in the metal, and the same negative result would be furnished by the explosion over the plate of a heap of loose gun-cotton of the same or greater weight than the charges detonated. The above method of experiment was devised, in the first instance, by Mr. Abel, in July, 1875, for comparing the quality of some specimens of Llandore steel proposed to be used by the Admiralty for ship-building purposes with samples of malleable iron, and it has since been employed by Mr. Adamson in carrying out a very useful series of experiments, recently communicated to the Iron and Steel Institute.

(To be continued.)

END-ON ILLUMINATION IN PRIVATE SPECTROSCOPY, AND ITS APPLICATIONS TO BOTH BLOWPIPE FLAMES AND ELECTRIC ILLUMINED GAS-VACUUM TUBES.*

By PIAZZI SMYTH,
Astronomer Royal for Scotland, and Past President of R.S.S. Arts.
(Continued from p. 146).

PART II. *Flame-Spectroscopy.*

THE various kinds of flame most frequently employed to render substances incandescent in spectroscopy, are—

- (1.) The alcohol lamp.
- (2.) The Bunsen gas burner.
- (3.) The coal-gas blowpipe driven by air.
- (4.) The coal-gas blowpipe driven by oxygen. And
- (5.) The oxy-hydrogen blowpipe.

Of these five kinds, I choose the middle one as a stand by; for while its pointed conical flame is more definite, precise, and workmanlike than the wavy loose flames of the first two, it is cheaper, more usually met with, and more frequently ready for acting, than the two latter; while it links us on to a very fair amount of heat for any flame-work, or to what we may consider a standard step in temperature throughout all these researches. The above coal-gas and air blowpipe has, moreover, the further recommendation that, dull as its blue-gray flame may appear to the eye, yet it contains several colours which separate into distinct, discontinuous bands under the spectroscopic; and they would probably be more often utilised for spectroscopic science if they could only be made decidedly brighter. But brighter it must be without any change of temperature, and also without our losing the use of the simple open flame to vapourise at pleasure adventitious and external matters in the usual flame spectroscopic manner.

Prof. Swan of St. Andrews, who first gave a large, scientific and indeed very noble account of this blowpipe flame and its spectrum, and gave it so far back as 1856, was so impressed with the importance of brightening, if possible, its faint bluish light, that he placed three small blowpipes (of his own ingenious making) one behind the other, and looked through all three flames at once. Thereby he was enabled to measure all the the leading details of four out of the really five coloured bands in this spectrum; but failed to see the lines in the first of these as to position, viz., the orange-amber band. After him several observers in London, Paris, and Manchester resorted to single or double blowpipes, but unfortunately in conjunction with pure oxygen gas; for by that emphatic addition, the temperature of their flames was so greatly raised, that they are all necessarily excluded from the present inquiry.

More recently I have obtained a copy from Paris of the late Padre Secchi's grand work entitled "*Le Soleil*" (2nd ed. 1875); and on p. 246 of vol. i.,—where that brilliant scientist has introduced, though without acknowledgment, a copy of my own Edinburgh Observatory sketch in 1872 of the whole five bands of the simple blowpipe spectrum,—he yet, in alluding to it in the text, speaks of the bands as being, in all ordinary cases witnessed by him, *three* only, and their colours "*green and blue*"—really citron, green, and blue; in which case he could only have seen the three brighter ones of the five.

In Prof. Roscoe's well-known volume of "*Lectures on Spectrum Analysis*" (1st ed. 1868), there is a coloured representation of the coal-gas spectrum with five bands, and some of them with lines; not perhaps intended to be very accurate, but most assuredly not indicating the

* Read before the Royal Scottish Society of Arts, February 20, 1879.

slightest appearance of any lines in the orange-amber band. The 3rd edition, of 1873,—which I have just referred to, contains, at p. 320, the same plate.

A more advanced style of pictorial representation is that contained in Plate III. of M. de Boisbaudran's admirable, in most of its plates unequalled, if not inimitable, work entitled "*Spectres Lumineux*" (Paris, 1874). Plate III. purports to represent the spectrum of the blue flame of coal-gas. Our five coloured bands are of course represented; but the lines, marked only in the citron, green, and blue bands, are broad and hazy; the observation having been confessedly made with a slit that was "not very narrow," and there are no lines at all on the very faint orange-amber band. Not are there any records of such things amongst the numerical measures,—though the existence of four lines is mentioned in an appendix as having just been seen when both a very strong blowpipe jet was employed, and some extraneous matters introduced into its flame, with the effect of considerably condensing it.

Such was the state of this question when, last winter, after trying many experiments with plain and simple coal-gas and air blowpipes (the coal-gas being merely taken out of the service-pipes of the house, and the air driven through its flame out of an india-rubber bag, with a pressure of 2 or 3 inches of water), it occurred to me, remarking the narrow but elongated figure of the brighter part of the flame,—viz., about $\frac{1}{2}$ inch in diameter and 2 inches long,—to try looking at it *end on*, in place of, as almost every spectroscopist had hitherto done, *transversely* to the axis of the flame; and of course quite close up to it in both cases. The result, without any other change, was almost magical; not only were five bands at once most brilliantly seen as to their colours, but the six or seven lines in the *first* of them, or the *orange-amber* band, hitherto only uncertainly made out by any one, were now the most beautiful series in the whole spectrum. Next the lines in the *citron* band showed themselves splendid for brightness, and the number of them, towards their vanishing side, much increased. In the still brighter *green* band, the first line stood forth in a manner to well deserve its quaint, Alexander Herschel title of "the green giant of carbo-hydrogen." The lines in the fainter *blue* band were yet admirably distinct, though closer than the others. And in the violet band, though no similar lines exist there, the distinction of the faint band, the strong band, and the one fine line between the two, was also well made out.

So much appeared with a very moderate prism-power on the spectroscope; but on applying a dispersion equal to 22° between A and H, or five times as much as might usually be employed, I gazed for a time in mute admiration on the scene then opened up. Such a scene of —; but, if you please, before I begin any attempt, which can hardly but prove weak and poor, to set before you some idea of what the really entrancing feature of that vision was, allow me just a minute to state why this particular spectrum is thought so very important, and is so very much sought after.

Wretched as may be the more publicly illuminating power of a grey blowpipe flame of coal-gas and simple air, it is the standard representative in spectroscopy of nearly half nature that does not, and nine-tenths of nature that does, burn. By day the spectroscopist, however far he may travel in the spectrum, from ultra red to distant lavender-grey, can always find out whereabouts he is by referring to the solar lines as seen either in the sun itself, or in his marvellous quality of light as reflected from blue sky, or a cloud, or a hill, or a house, or from snow, or from anything whatever which reflects any daylight at all. But at night, when there can be no such light to reflect,

and the last of the gloaming is gone, and there may be no moon nor planet, the young spectroscopist is either lost in darkness or bewildered on a chromatic ocean without fiducial marks of any kind. For though he turns to the light of a lamp for aid, or to any one of ten thousand gas-lights, their bright flame—bright from the incandescence of little solid particles of carbon—offers, like all other incandescent solids, only a continuous spectrum, wherein the colours blend undistinguishably one into the other from the red through the citron to the violet. Hence the poor youth at night would have been altogether at sea, when spectroscoping something totally new in heaven or on earth, had not our excellent Fellow of former years, and still only removed by the breadth of the Fifth, Prof. Swan, shown that all the substances hitherto used by man for artificially illuminating the darkness of night (such as wax, oil, tallow, turpentine, ether, alcohol, generally carbo-hydrogens)—all of them give, in the blue base of their flames, one and the same spectrum of but five coloured bands and their several innate half-dozen or so of lines; the same spectrum, in fact, as that of the flame of our favourite kind of blowpipe, though that little instrument gives it more neatly, clearly, and without the swamping effect on its best characteristics of the dense continuous spectrum derived from the more or less yellow light in the upper parts of most kinds of simple lamp-flame.

Now I had for a long time, when voyaging in the Mediterranean, actually used an alcohol lamp with a flame made purposely long and thin, in order to develop its blue base and hide its yellow top;—I had, I say, employed those carbo-hydrogen spectral lines as given by alcohol, for reference in Aurora and Zodiacal Light spectroscopy. But I gave it up at last on finding how much cleaner and freer from apparently adventitious haze the selfsame bands and their lines appeared in the blowpipe flame of coal-gas* and common air. And yet the lines did not appear even there without any haze at all! In fact, there was still so much of it hanging to them, and interfering to such an extent with the easy visibility of some of the fainter lines, that I am afraid in my haste I thought it a nuisance, an abnormal interloper, and held it as mere trash to be got rid of in any possible way. But it would not go; and now, on looking once again at the old green band and all its plaguing haze, made denser than ever by the brightness of the end-on view, but on this occasion *extra analysed, or spread out, by the tremendous dispersive power just described*—behold! all that haze, instead of becoming more hazy and diffuse than ever, was resolved neatly and perfectly into innumerable, exquisite, fine lines or linelets! These miniature lines of light, indeed, filled the whole field of view; asserted themselves to be as necessary to the spectrum of coal-gas and air as any other part of it; and had, besides, a beautifully regular progressive arrangement of their own, gradually increasing in distance asunder, as the older band lines—now looking like huge and far-between Cyclopes—decreased in theirs, as they all tended on, in the direction of increasing refrangibility, towards the violet.

Something of the same kind, and even more distinct in many of its details, has already been seen, I am aware, by many other persons, in certain spectra both of oxygen blowpipes and electric sparks; but those spectra have greatly elevated temperatures, and I am confining myself here, for the reasons already stated, to simple coal-gas and atmospheric air blowpipes only. And not so much even there, to what may be done absolutely by increasing their size immensely, as in Prof. Roscoe's blowpipe with "a blue flame 3 feet long;" but to the differential effect of looking at one and the same blowpipe flame, whether large or small, *first transversely, and then end-on*. The

* This increase of the first expected effect was owing to the hollow nature of flame, and the superficiality of its light. So that when viewed end-on, the whole of the illumination previously seen in the long side profile, was now merely condensed to a disc equal in area to a cross-section of the flame, but was further concentrated into a thin circumference of that disc.

* At a distance from gas supplies it is well to know that an equivalent to coal-gas for the spectroscope, and perfectly safe, may be produced by passing a stream of air through a vessel containing a considerable surface of benzene, or other hydrocarbon liquid in a vapourising condition at ordinary temperatures.

improvement, too, of vision for spectroscopy by the end-on method is so decided, and at the same time is obtained so simply and economically, or without any increase of expense whatever, that it would doubtless have been adopted everywhere long ago, and not left for me to advocate, had not the chemists, a large and influential body of men, and to whom we all owe much (yet said, in former times, if not still, to positively rejoice in living in the midst of flames, and smoke, and soot),—if, I repeat, the chemists had not so generally kept to their sad, dirty plan of letting their salts burn and fizz in a flame close in front of the naked slits of their spectroscopes.

Hence Mr. Rand Capron, in his "Photographed Spectra" of chemical elements, following lately the supposed orthodox method, finds himself compelled to write—"Much trouble was experienced in keeping the slit-plate clear from metallic beads and other impurities." And he suggests that in future it would be a great advantage to have the whole slit-plate gilded, and the slit-jaws formed of obsidian, platinum, or gold. Vain resource, however, if the spitting flame be still preserved close by, and quite inapplicable to any end-on use of it; for that would imply directing the full blast of the blowpipe right on the slit-plate and melting it down altogether. But my rude spectroscope having been built up at home, and primarily for operating on the distant light of the Aurora, as seen occasionally from an upper chamber at No. 15, Royal Terrace, Edinburgh, I was compelled from the first to bring such very far-off light to the slit by an anterior image-forming object-glass. And once having made experience of that excellent method of using an optical image of the thing, and not the thing itself, especially when that thing is worse to touch than a red-hot poker, have kept to it ever since for table work close by, as well as celestial objects a long way off.

The above, therefore, removing the last of the practical difficulties in the way of any one desirous of enjoying the advantages of end-on illumination in his flame spectroscopy, I close this part of the paper by referring to the Appendix for the following tables of useful data:—

Table 1. Colours of the spectrum by spectral place.

- " 2. The blowpipe flame's spectrum, seen end-on under small dispersion.
- " 3. Certain parts of the blowpipe flame's spectrum, under higher dispersion.
- " 6. Wave-number places of certain practical data.

(To be continued).

PROCEEDINGS OF SOCIETIES.

NEWCASTLE CHEMICAL SOCIETY.

(Concluded from p. 133.)

"Tennant's Nitrometer," by Messrs. BRADY and MARTIN.

This apparatus is used for testing the amount of nitrous compounds existing in sulphuric acids from the Gay Lussac and Glover towers, and also in the chamber acids. The three higher oxides are each reduced to NO, and from the volume of the latter, obtained from a given quantity of the acid, the nitrogen, nitrous acid, or nitric acid may be easily calculated.

Description.—B is a three-way stop-cock, having a passage between the tube C and the cup A, and between C and the waste pipe E. G is a tube graduated to 30 c.c. in fifths. A piece of caoutchouc tubing is fixed to the outlet of the globe D, and carried to a bottle or reservoir for mercury, from whence the graduated tube may be filled.

A measured quantity of the acid to be tested is then

introduced into the cup A, and, by lowering the mercury reservoir and opening the stop-cock, allowed to pass into the graduated tube. The stop-cock is then closed, and the column of acid vigorously shaken till its reaction on the mercury is completed.

Mr. STARKS, at the invitation of the Chairman, gave a practical description of the mode of using the nitrometers, remarking at the same time that the two instruments were identical in principle, and almost identical in detail. The instrument with the bulb was the form in use at Messrs. Tennant's works, at Hebburn, and he had used it for some time before he was aware that Dr. Lunge had contrived a similar piece of apparatus. No doubt Dr. Lunge was equally innocent of any knowledge of their doings, and the instruments were thus simultaneously invented. He admitted, however, that they were indebted to Dr. Lunge for the name—a name so obviously appropriate, that it was not desirable to invent a second.

The CHAIRMAN then described an experiment he had recently performed on the production of light, by passing a current of electricity through a slender rod of carbon enclosed in an exhausted globe, the physical results of which experiment he thought might be interesting to the members. He had obtained the current from a Siemens dynamo-electric machine of the second or 6000 candle size. On passing the current, the rod became heated to such an intense degree as to cause it to glow with great splendour. The glass became coated with a sooty deposit on its inside; and the rod of carbon, which before use had been exposed to an intense heat, to secure as much contraction as possible, became curved to the form of a bow, as if from softening.

Prof. HERSCHEL remarked that there was every appearance of the carbon having become plastic with the heat; and, unless he were right in thinking that Deville had observed the same, it was the first time carbon had been known to have been rendered plastic; but he had a strong impression that Deville had made a similar observation. The opportunity of seeing the effect, however, was very interesting.

"Halden and Thornton's Modification of the Cyanotype Process, for Copying Drawings and Tracings," by Mr. JAS. DONNELLY.

* An octavo book, with 37 remarkable plates, published by E. and F. Spoe, Charing Cross, 1877. See its page 8.

The CHAIRMAN remarked that this was but a slight modification of the Cyanotype process of Sir John Herschel, one of the earliest and simplest of the photographic processes, a process which was not adapted for artistic work, but was eminently useful for copying engineers' and architects' drawings, as it required no knowledge of chemicals or photographic art on the part of those using it; the sensitive paper being tolerably permanent, was supplied ready for use, and, after exposure, required nothing but washing in pure water to fix it.

Mr. BERKLEY said, though the process was not new, it was no less valuable, and was in constant use in the drawing office at Messrs. Palmer's works at Jarrow, and many other large establishments.

Prof. HERSCHEL confirmed what had been said by the Chairman and Mr. Berkley about the origin, the utility, and the simplicity of the process. He said it was extensively used on the Continent, and in illustration he laid upon the table a collection of very large and beautiful cyanotype prints from draughtsmen's designs which he had received from Belgium, some of the designs covering 8 to 10 square feet of sensitive paper.

"Varley's Electric Harmonium," by Prof. HERSCHEL.

It consists of a gamut of tuning-forks arranged as spring contact-breakers. A key-board is attached, and the depression of any key directs the current through an electromagnet, under the influence of which the fork applied to it vibrates, and the corresponding fork is thereupon set in similar vibration. The feeble tone of the forks was much increased when a telephone was placed in circuit, and was still further increased when the telephone was replaced by a piece of apparatus acting like a Leyden jar, and consisting of a sheet of thin gutta-percha, with perforated zinc on one side, and thin tin-foil on the other.

Mr. REYNOLDSON exhibited an automatic arrangement for the continuous supply to an evaporating-basin of a large given quantity of water; also a model of an arrangement for indicating the flow of acid through a Glover or Gay-Lussac tower. As these attracted considerable attention, and were not accompanied by a note, Mr. Reynolds was requested to bring them under the attention of the Society at some future meeting.

"Reagent Bottles with Embossed Labels." Messrs. BRADY and MARTIN exhibited microscopes by Beck and by Zeiss, and a set of reagent bottles, the labels of which were embossed in relief on the surface of the glass, and rendered more visible by being roughed by grinding, thus forming dull letters on a bright ground.

Swan's dry photographic plates were the subject of an interesting experiment, their extreme sensitiveness enabling the Chairman to obtain two successful prints from a negative; one being exposed two seconds to the light of a common bat's-wing burner at the distance of one foot, and the other exposed to the same light for only half this time.

A vote of thanks to the exhibitors and others who had contributed information to the meeting brought the proceedings to a close.

CORRESPONDENCE.

AUSTRALIAN EUCALYPTI.

To the Editor of the Chemical News.

SIR,—My old friend, Baron Ferdinand Von Mueller, Director of the Victorian Botanical Department, has very kindly sent me the special information you wished as to the comparative analysis of some of the various Eucalypti, by which you will see that the celebrated *E. globulus* is by no means the richest in the essential oil which gives the peculiar sanitary value to this class of trees, although it

is the most "taking" in its earlier stages, from the rapidity of its growth and fulness of foliage.

"*Eucalyptus Amygdalina*."

"It is this species which yields more volatile oil than any other tested, and which therefore is largely chosen for distillation; thus it is also one of the best for subduing malarian effluvia in fever regions, although it does not grow with quite the same ease and celerity as *E. globulus*. The respective hygienic value of various Eucalypts may to some extent be judged from the percentage of oil in their foliage, as stated below, and as ascertained by Mr. Bosisto at the author's instance, for the Exhibition of 1862:—

<i>E. amygdalina</i>	3'313	per cent volatile oil
<i>E. oleosa</i>	1'250	" "
<i>E. leucoxylon</i>	1'060	" "
<i>E. goniocalyx</i>	0'914	" "
<i>E. globulus</i>	0'719	" "
<i>E. obliqua</i>	0'500	" "

"The lesser quantity of oil of *E. globulus* is, however, compensated for by the vigour of its growth and the early copiousness of its foliage. The proportion of oil varies also somewhat according to locality and season. *E. rostrata*, though one of the poorest in oils, is nevertheless important for malarian regions, as it will grow well on periodically inundated places, and even in stagnant water not saline. *E. oleosa* (F. v. M.), from the desert regions of extra-tropic Australia, might be reared on barren lands of other countries for the sake of its oil. According to Mr. Osborne's experiments, Eucalyptus oil dissolves the following, among other substances, for select varnishes and other preparations:—Camphor, pine-resins, mastich, elemi, sandarac, kauri, dammar, asphalt, xanthorrhæa-resin, dragon's blood, benzoe, copal, amber, anime, shellac, caoutchouc, also wax, but not gutta-percha. These substances are arranged here in the order of their great solubility. The potash obtainable from the ashes of various Eucalypts varies from 5 to 27 per cent. One ton of the fresh foliage of *E. globulus* yields about 8½ lbs. of pearl-ash. A ton of the green wood, about 2½ lbs.; of dry wood, about 4½ lbs. For resins, tar, acetic acid, tannin, and other products of many Eucalypts see various documents and reports of the writer, issued from the Melbourne Botanic Garden."

I have had so many enquiries from different parts of the world for seeds, and as to what sort will suit various soils and climates, that I have asked Messrs. C. J. Cresswell and Co., seedsmen, of Sydney, to make a special point of securing pure seed of various kinds of trees, and from various parts of the Colony, so as to suit either tropical or cold climates (as whilst we never see frost in my garden near Sydney, yet at Kiandra the snow lies for months!); and I trust, therefore, that in a few years' time, with a little patience and experience, the right sorts to thrive, either in temperate England or torrid India, may be accurately known, and reliable plantations thus secured.

The Baron (at Melbourne) and Mr. Charles Moore, F.R.L.S., Director of our Sydney Botanical Department, will both be happy to afford any special information to parties really requiring it for practical use; but as amongst the three of us we have already answered over one hundred letters on the subject, I trust that the information therein given will be "passed on" by the recipients as much as possible, so as to save us a little, as no leading Government officials or men of business in these Colonies have any spare time worth speaking of.—I am, &c.,

R. D. ADAMS.

Sydney, N.S.W., February, 1879.

DYEING.

To the Editor of the Chemical News.

SIR,—In the otherwise accurate report of "Researches in Dyeing: Part II.," which appeared in the CHEMICAL NEWS (vol. xxxix., p. 161), Mr. Campbell and myself are repre-

sented as considering "the heat and souring used by dyers" to be "unadvisable." The statements actually made in the papers were as follows:—"The heat and souring to which dyers usually have recourse are questions quite apart from the intrinsic deposition of the pigment." . . . "We think it advisable not to maintain this blue so long as is usually done at the dissociation temperature." For HCl read KCl.—I am, &c.,

EDMUND J. MILLS.

Andersen's College, Glasgow,
April 11, 1879.

LOSS OF NITRE IN VITRIOL MANUFACTURE.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxix., p. 198, I noticed a letter from Dr. G. Lunge, in which he asserts that all fear of any appreciable loss of nitrous compounds in the Glover tower has vanished.

I have opposed Dr. Lunge on a former occasion by publishing in *Dingler's Journal* (vol. 227, p. 465, also vol. 228, p. 545), an account of some experiments on the subject of denitration, and a statement showing the loss of nitrate of soda as incurred at Messrs Gaskell, Deacon, and Co.'s works. Since that time I have continually watched the loss of nitrate of soda at these works, and applied the most refined methods of ascertaining these losses. The result of this labour has been confirmatory of all the figures I published at that time.

Chance has now presented me with the results obtained at many of the largest English alkali works. I am not at liberty to publish these. They are the results of daily tests of the exit gases extending over more than one month. The samples were all drawn by continuous aspirators and were analysed by the same method in each work. The volumes were corrected for temperature and pressure. These results and a few generally acknowledged facts enable me to make the following statements with regard to the loss of nitre in the manufacture of sulphuric acid.

I have for convenience divided the losses into two classes. The first class includes losses due to mere mechanical causes, such as the loss incurred by leakage, by the withdrawal of nitrous anhydride from the system either by imperfectly denitrated vitriol or by the exit gases. The second class I called chemical losses, because they are due to the reduction of the higher oxides of nitrogen to either nitrous oxide or nitrogen.

I. Mechanical Losses.

(a.) *Nitrous Anhydride withdrawn from the System by Means of Exit Gas.*—Taking the average amount of oxygen, leaving the Gay-Lussac column at 10 per cent, and the average amount of nitrate of soda used at 4 per 100 of sulphur passing into the chambers, the results of seven different large works show that the loss of nitre from this source is about 10.5 per cent of the nitrate used.

(b.) *Loss of Nitrous Anhydride by Imperfect Denitration.*—This loss is acknowledged by all authorities to be small. Mr. Davies (CHEMICAL NEWS, vol. xxxvii., p. 155) allows from 10 to 15 per cent of nitrate as lost by vitriol which was not at all denitrated. In Messrs. Gaskell, Deacon, and Co.'s works the loss from this source hardly ever reaches 6 per cent. From analyses of Glover-tower vitriol, published by Mr. Maclear, I calculate a loss of 2 per cent; Mr. Davies usually finds traces only in Glover-tower vitriol. If I assume 10 per cent of loss from imperfect denitration I greatly exaggerate.

(c.) *Loss from Leakage of Apparatus.*—This loss cannot be estimated directly. The loss of sulphur from all sources does not exceed 10 per cent. Most of this is lost as sulphurous acid, passing into the chimney with the exit gas, and into the air from the kilns. The amount leaking into the air from the chambers is trifling. Hence the nitrogen acids leaking into the air from the chambers

are trifling in amount also; but I will allow 5 per cent of nitrate of soda for this loss.

II. Chemical Loss.

This loss is incurred in the Glover tower, in the chambers, and, according to Mr. Davies, in the Gay-Lussac column, though not there in form of reduction to nitrous oxide. This chemical loss is exceedingly difficult to trace and to measure. As regards the chambers Mr. Davies's paper proves (if it proves anything at all) that the amount of nitre lost in this way in chambers not connected with Gay-Lussac and Glover columns is usually from 10 to 15 per cent. But allow 20 per cent for systems which are connected with such columns and you will find that:—

The exaggerated total losses from all sources amount to 45 per cent, leaving 55 per cent of the nitrate of soda used still to be accounted for. These 55 per cent represent the chemical loss from the Glover tower, or the Gay-Lussac tower, or both.

Mr. Davies thought he had explained this loss by the oxidation of the arsenious acid to arsenic acid in the Gay-Lussac column by the following reaction:—

and he gave it as his opinion that the N_2O_2 escaped into the chimney. But this explanation will not hold good, for two reasons: (1.) Because this reaction does not take place even at temperatures (220° to 230° F.) which never obtain in Gay-Lussac columns. (2.) Even if the reaction did occur to an infinitesimal amount, it does not follow that the nitric oxide is lost, since the gas usually contains sufficient oxygen (8 to 10 per cent) to re-convert it into higher oxides; and any escape of such higher oxides is already included in the mechanical loss (a).

The mere fact that As_2O_5 occurs in Gay-Lussac vitriol can be explained without having recourse to the imaginary reaction on which all Mr. Davies's calculations are based.

The loss of nitre from chemical causes cannot therefore be explained as taking place in the Gay-Lussac column, and, since only the Glover tower remains, I cannot agree to any such statement, that all fear of appreciable loss of nitre in that piece of apparatus has vanished.

It is not, in my opinion, any service to the manufacturer to put him off his guard and prevent further search by such statements.—I am, &c.,

FERDINAND HURTER.

Laboratory of Gaskell, Deacon, and Co.,
Widnes.

CHLORIDE OF CALCIUM.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxix., p. 122, there is an answer from Messrs. Gaskell, Deacon, and Co., to my notice on chloride of calcium, which you kindly published (p. 97). Allow me to add a few more words.

Very little knowledge of chemistry would be required for any person to know that chloride of calcium is a by-product in the manufacture of carbonate of soda by the Leblanc process and of bleaching-powder by the Weldon process. I wished to call the attention of manufacturers to the production of calcium chloride, because it is produced in large and increasing quantities in the manufacture of carbonate of soda by the ammonia process, which quantities are to be added to those produced by the other manufactures. Messrs. Gaskell, Deacon, and Co., advertise the sale of this product. I never doubted that it is sold by them; but I should like to know at what price these gentlemen used to sell it before the introduction of the Solvay process, which has considerably lowered its market value. It is on account of the low price and the large production that I wished to hear of new processes in which it could be used.—I am, &c.,

O. GLUGE.

Sarrebruck, April 11, 1879.

MANUFACTURE OF PICRIC ACID.

To the Editor of the Chemical News.

SIR,—I noticed in the abstract from the *Chemiker Zeitung* (No. 10, 1879), which appeared in the *CHEMICAL NEWS*, vol. xxxix., p. 150, on the above subject, that a certain J. Marzelli proposes "to add slowly the sulphacid of phenol to concentrated nitric acid." I may just mention that I know of at least one English manufacturer who used this method and manner of operating advantageously some ten years ago. So long ago as this I have also myself used the method, allowing the sulphacid to fall drop by drop through a tap-funnel into the concentrated nitric acid. This plan is an excellent one, and I am under the impression it is better and more widely known to manufacturers than J. Marzelli is aware of. I am under the impression, too, that I have seen, about a year and a half ago, more than one student in the Technical Laboratory of the Polytechnicum of this town preparing picric acid according to the above-mentioned scheme, as that of a known technical process.—I am, &c.,

WATSON SMITH, F.C.S., F.I.C.

Zürich, April 6, 1879.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin, No. 16, 1879.

Action of Anhydrous Hypochlorous Acid upon Ethylen.—E. Mulder and G. J. W. Bremer.—The authors obtained a compound represented by the formula— $C_4H_6Cl_2O_2$.

Constitution of Ultramarine.—Arthur Lehmann.—Not susceptible of useful abstraction.

Double Salts of Calcium Sulphate with other Salts and Behaviour of Gypsum in Certain Saturated Saline Solutions.—R. Fassbender.—A precipitate which the author had formerly obtained by adding solid sulphate of potassa to a saturated solution of gypsum and potassic chloride proved to be a mere mixture of the two sulphates with varying quantities of potassic chloride. The latter salt is very obstinately retained by the sulphates of calcium and potassium as is also potassic nitrate. The author confirms Struve's result that calcio-potassic sulphate is obtained by the action of potassic chloride upon gypsum.

Action of Hydrogen upon Meta-nitro-para-trichlor-acetoluyd and Meta-nitro-para-valeryl-toluyd.—T. Friederici.—Not suitable for abstraction.

New Method of Preparing Chrysaniic Acid.—T. Friederici.—The author oxidises dinitro-acetoluyd by the action of potassium pyro-chromate along with moderately dilute sulphuric acid.

On Chlor-nitro-anilins.—F. Beilstein and A. Kurbatow.—The authors examine the nitro-dichlor-anilins with para-, ortho-, and meta-position of the chlorine atoms.

On so-called Dichlor-azo-phenol.—R. Hirsch.—As regards the preparation and properties of dichlor-azo-phenol the author confirms the statements of its discoverers, Schmitt and Bennewitz. By treatment with hydrochloric acid he obtained from it hydrochlorate of dichlor-amido-phenol.

On Cinchotenicin.—O. Hesse.—The author gives this name to an isomer of cinchotenin. It is a dark brown, perfectly amorphous mass, very brittle, and yielding a yellow powder. It is readily soluble in water, alcohol, chloroform, dilute acids, ammonia, and alkaline lyes, but

is insoluble in ether. The yellowish brown solution turns the plane of polarised light slightly to the right.

Action of Cyanogen upon Amido-benzoic Acid and Anthranilic Acid in Aqueous Solution.—P. Griess.—From the reaction of cyanogen upon metamido-benzoic acid the author obtained amido-benzoic percyanide and a new compound, cyan-carbimidamido-benzoic acid. The latter of these compounds has an acid reaction, but forms salts both with bases and acids. At elevated temperatures and on treatment with acids it proves very unstable, and a number of interesting compounds are produced by its decompositions. The action of cyanogen upon anthranilic acid in aqueous solution gives rise to bicyan-amido-phenol.

Pinacons and Pinacolins.—W. Thörner and T. Zincke.—The authors give an account of the three aceton-phenon-pinacolins.

Diphenyl-methyl-acetic Acid.—W. Thörner and T. Zincke.—This compound, $C_{15}H_{14}O_2$, crystallises from dilute alcohol in white ramified leaflets, but from pure alcohol in shining transparent cubes. It melts at 173° . Several of its salts are described.

Hydrocarbon, $C_{16}H_{12}$, from Phenyl-glycol.—A. Breuer and T. Zincke.—This hydrocarbon, on oxidation with chromic acid, is converted into a quinon, $C_{16}H_{10}O_2$, which in solution is readily polarised under the influence of light. With neutral and acid alkaline sulphites it yields well-crystallised compounds. On treatment with alkali there is formed an oxy-quinon, $C_{16}H_{10}O_3$, and with ammonia an oxy-imido-compound, $C_{16}H_{11}NO_2$.

Certain Derivatives of Phenyl-acetic Acid.—O. Stöckenius.—By the reaction of ammonia upon phenyl-brom-acetic acid the author obtains phenyl-amida-etic acid along with amygdalic acid.

Dissociation of Sal-ammoniac.—C. Böttger.—The bulb of a bulb-tube is charged with sal-ammoniac, and the tube being placed nearly horizontally, a strip of red litmus paper is placed in the upper end of the tube and a strip of blue litmus in the lower. The bulb is then heated, when ammonia, being the lighter component, escapes from the upper end and turns the red paper blue, and hydrochloric acid, being the heavier, flows from the lower end and turns the blue paper red. Success depends on the inclination of the tube.

Physiologically Active Basic Constituent of the Dita Bark (Alstonia s. Echites scholaris).—Erich Harnack.—The author's daitain, $C_{22}H_{30}N_2O_4$, is a true chemical individual, and is not to be confounded with the daitain of Grupe, a mere mixture. Its physiological action upon vertebrate animals agrees with that of curare.

On Sulpho-selen-oxy-tetra-chloride.—F. Clausnizer.—The composition of this body is SO_3SeCl_4 .

Further Methods of Formation of Sulpho-selen-oxy-tetra-chloride.—F. Clausnizer.—The author has obtained this compound by the joint action of pyro-sulphuric acid and selenium tetra-chloride, of pyro-sulphuryl-chloride and selenium tetra-chloride, and of sulphuryl-hydroxyl-chloride and selen-oxy-chloride.

Action of Sulphuryl-hydroxyl-chloride upon Chlorides of Titanium, Antimony, Tin, and Silicon.—F. Clausnizer.—The author succeeded in obtaining a double compound in the case of titanium only.

Experiments on the Preparation of Sulphuryl-hydroxyl-bromide and Sulphur-oxy-tetra-bromide.—F. Clausnizer.—The results of the experiments appear to have been negative.

Constitution of Ultramarine.—R. Rickmann.—Not available for abstraction.

Contributions to the Voluminar Law and Steric Law.—H. Schröder.—From this interesting and important paper we can select only the following results, to which the author draws more special attention:—The organic elements, C, H, O, N, have in general the same

space-filling power of one stere, though there occur, e.g., in water of hydration $=H_2O_4$, certain condensations or expansions of individual elements which, as will subsequently appear, are characteristic of organic nuclei. A second very remarkable fact is the extraordinary constancy of the voluminar constitution with which certain elements and their compounds are contained in the most different groups. A third very important fact is the simplicity of the volume-molecules of all salts. Their volume-molecules are almost always monatomic, or at most di-atomic, the latter being the case only in iron spar, calcareous spar, and sodic nitrate.

Die Chemische Industrie.

No. 1, Jan., 1879.

Manufacture of Potassium Iodide.—E. Schering.—Inserted elsewhere.

Process for the Extraction of Sulphur from Alkali-waste, Gypsum, Heavy Spar, and Sulphurous Acid, and recovery of the Earths previously Combined with Sulphur in the State of Carbonates.—Max Schaffner and W. Helbig.—This process cannot be fully described without the accessory plates. It is based upon the decomposition of calcium sulphide and magnesium chloride, which latter salt has no action upon calcium carbonate. The residue from this reaction, after the expulsion of the sulphuretted hydrogen and which contains magnesia and calcium chloride, is exposed to the action of carbonic acid, when magnesium chloride is reproduced and calcium carbonate formed.

No. 2, February, 1879.

Report on the Stassfurt Industry.—Dr. B. Bernhardt.—The improvements recently introduced aim chiefly at effecting economy in the consumption of carnallite and of fuel. It is proposed to evaporate the various liquors in closed boilers under a slight pressure. Continuous evaporation is likewise suggested, the difficulty being the removal of the salts from the heated surfaces as deposited. The conversion of potassium chloride into sulphate by double decomposition with Epsom salts is advantageously effected under Dr. Borsche's patent. The mixed salts are successively lixiviated with quantities of water insufficient for complete solution. The bulk of the magnesium chloride is removed in the first liquors. Many practical men, however, still prefer to treat the potassium chloride with sulphuric acid in a Jones salt-cake furnace.

Action of Magnesium Chloride upon Steam Boilers with reference to the Magnesia Process of Purifying Feed-water.—E. Bohlig.—The author concludes from his experiments that magnesium chloride has no corrosive action as long as a slight excess of magnesium carbonate is present.

No. 3, March, 1879.

Meeting of the Association for Promoting the Interests of German Chemical Industry.—In a petition to the Reichstag concerning the use of alleged poisonous colours, the Association point out that certain dyes, such as red corallin and aurantia, denounced as poisons, have subsequently been proved perfectly innocent. They pray that no colour may be prohibited till it has been formally pronounced dangerous to public health by a commission of specially qualified chemists and physiologists after a due scientific examination. At the sessions of February 23, 24, and 25 a long debate ensued on the protective duties to be imposed on foreign chemicals, and a tariff was agreed upon to be submitted to the Reichstag.

South American Production of Iodine.—Dr. G. Langbein.—The processes in use for separating iodine from the mother-liquors of the nitre refineries may be divided into three classes. (1.) The liquors, without previous concentration, are mixed with a quantity of sodium sulphite corresponding to the iodine present, the iodine separated out is filtered through linen bags, washed,

pressed, and sublimed. (2.) The mother-liquors are treated with sodium sulphite or bisulphite till the precipitated iodine is converted into hydriodic acid, which is then precipitated as cuprous iodide by a solution of copper sulphate and sodium sulphite. (3.) The iodine in the mother-liquors is concentrated by fractionated evaporation and crystallisation, and the iodine, mixed with a proportionate quantity of sodium sulphite or bisulphite, is recovered by distillation from the acidified liquid.

Efficacy of Compounds Employed as "Antichlore."—Dr. G. Lunge.—The author has submitted the *modus operandi* of some of these agents to a critical examination. The hyposulphite of soda (now thiosulphate) was said by Fordos and Gélis to undergo a direct conversion into sulphate. Its reaction with chlorine, as well as that of the sulphites, gives rise to free acid, which, if not at once washed out, attacks the iron of the machinery, forming injurious salts which render the paper brittle, yellow, or spotty. There is no sufficient proof that the use of hyposulphite leads to the deposition of sulphur and the formation of acids by its gradual oxidation if the half-stuff has been properly washed. The efficacy of hyposulphite is much less than has been assumed. Ammonia as an antichlore appears to act only at an elevated temperature with the emission of an unbearable odour.

No. 12, 1879.

Adulteration of Wax.—Dr. Max.—Bee's-wax is often sophisticated to the extent of 33 to 50 per cent with ceresin, a mixture of refined earth-wax and caranaba-wax. Pure bee's-wax has a higher specific gravity (0.94 to 0.97) than these ingredients or than the mixtures, which range from 0.876 to 0.937. Prof. v. Wagner recommends the sample to be placed in dilute alcohol of sp. gr. 0.945, and rejected as impure unless it floats.—*Dingler Polyt. Journal.*

Detection of Starch in Milk.—Dr. Vulpinus coagulates the sample with a few drops of acetic acid, heats to a boil, filters, and adds to the clear whey an aqueous solution of iodine, which at once produces a blue cloud if starch be present; 5 milligrams were thus distinctly recognised in 5 c.c. of milk.—*Pharm. Zeitung.*

Chloride of magnesium is recommended as a fluid for filling wet gas-meters.

No. 13, March 27, 1879.

Distillation of Coal-tar.—The author gives an account of the distinctions between the products obtained by the dry distillation of wood, peat, lignite, and coal, and shows that according to the recent experiments of Letny, Liebermann, and others, wood-tar and petroleum-tar, &c., if passed through ignited tubes, yield the same products as coal-tar, which he considers may be of great importance for the production of the aniline and alizarin colours. He then gives an account of the distillation of coal-tar with especial reference to anthracen.

At Dortmund, on March 22, Dr. Schridde delivered a lecture on "Chemistry as a Trade, an Art, and a Science."

In Switzerland the factory inspectors receive a yearly salary of 6000 francs, with an addition of 7 francs daily for their expenses when travelling on official business and 5 francs more if detained over night.

Moniteur Scientifique, Quasneville.

February, 1879.

This issue is almost entirely taken up with a translation of Sir B. C. Brodie's well-known "Chemical Calculus," a continuation of the discussion between MM. Berthelot and Pasteur, a notice of foreign chemical researches consisting entirely of extracts from the *Berichte*

der Deutschen Chem. Gesell., an account of the recent great discovery by Mr. Norman Lockyer, and a very lengthy notice of a work on applied physiology by M. L. Fignier.

Detection of Tarry Matters in Ammonia.—The well-known nitric acid test is recommended, which, in presence of aniline, toluylidn, &c., gives a gooseberry-red colour.

Ethyl-green and Malachite Green.—Another Swiss firm, M.M. Gerber and Uhlmann, of Bâle, announce that their green colour is prepared by the reaction of the hydride of benzoin upon ethyl- or methyl-aniline, and that it does not fall within the limits of the patent for "malachite green."

Archives Néerlandaises des Sciences.
Tome xliii., 4me Livraison.

Researches on Quinamin.—A. C. Oudemans.—The author first gives the analysis of the crude mixture of alkaloids known as quinetum, which he finds composed of:—

Cinchonin	37.0
Quinin	6.1
Cinchonidin	22.9
Quinamin	4.5
Amorphous alkaloids	21.1
Carbonate of soda	2.9
Water	2.7

From this mixture he separates quinamin, $C_{19}H_{24}N_2O_2$, the properties, reactions, and salts of which he describes in detail.

This issue contains no original chemical matter.

MISCELLANEOUS.

Royal Institution of Great Britain.—The following are the arrangements for the Lectures after Easter:—

Ernst Pauer.—Three Lectures on Schubert, Mendelssohn, and Schumann (with Musical Illustrations); on Tuesdays, April 22 to May 6.

Professor Dewar, M.A., F.R.S.—Fives Lectures on "Dissociation;" on Thursdays, April 24 to May 29.

H. H. Statham.—Four Lectures on the Leading Styles of Architecture Historically and Æsthetically Considered; on Saturdays, April 26 to May 17.

Professor Karl Hillebrand.—Six Lectures on the Intellectual Movement of Germany from the Middle of the Last to the Middle of the Present Century; on Tuesday, May 13; Mondays, May 19, 26, June 2; Tuesday, June 10; and Thursday, June 12.

John Robert Seeley, M.A., Professor of Modern History, Cambridge.—Four Lectures on Tuesdays, May 20, 27, June 3; and on Thursday, June 5.

Professor Henry Morley.—Three Lectures on Swift; on Saturdays, May 24 to June 7.

The following are the probable arrangements for the Friday evening Meetings after Easter, to which Members and their friends only are admitted.

Friday, April 25.—Francis Galton, M.A., F.R.S., M.R.I. Generic Images.

Friday, May 2.—Professor John G. M'Kendrick, M.D. The Physiological Action of Anæsthetics.

Friday, May 9.—Sir John Lubbock, Bart., M.P., F.R.S., M.R.I. The Habits of Ants.

Friday, May 16.—Professor A. Cornu. Etude Optique de l'Elasticité. (In French.)

Friday, May 23.—W. H. Preece, M.R.I. Multiple Telegraph, or Duplex and Quadruplex Telegraphy.

Friday, May 30.—Grant Allen. The Colour-sense in Insects; its Development and Reaction.

Friday, June 6.—Professor Dewar, M.A., F.R.S.

Friday, June 13.—Frederick J. Bramwell, F.R.S. The "Thunderer" Gun Explosion.

Another Agricultural College.—A correspondent of *The Live Stock Journal* writes as follows:—"With considerable satisfaction I learn that the starting of another Agricultural College is already under contemplation, for it has long been evident that the Cirencester institution has neither attained the position which its promoters had in view, nor conferred on the agriculture of the country the benefits which were reasonably expected from it. I hail therefore with pleasure the intimation that the four leading professors at Cirencester, viz., Professors Church, Tanner, Fream, and Sheldon, having been requested by influential persons to consider the idea, are already reducing to form the scheme of a second Agricultural College, for which, I have no doubt, they will receive all the help and patronage that are necessary to bring their project into successful operation. There is, indeed, room for several agricultural colleges, and no doubt the Cirencester one would have had a better tale to tell if two or three rival establishments had existed to spur it on. I regard the starting of a second Agricultural College in England as an event that is calculated to do a much-needed service to the parent institution, and I venture to predict that each of the two colleges will do better than the single one has hitherto done, provided the Council will seriously take in hand those changes which are evidently so much needed at Cirencester."

NOTES AND QUERIES.

Honey.—Can any of your readers give me references to any late (within ten years) investigations of the chemical composition of honey?—E. H. S.

Insurance of Tar Distilleries.—Can any of your readers give the name of any Fire Insurance Office of good standing which effects insurances on risks as hazardous as tar distilleries?—W. A. R.

Testing of Coal-Tar Products.—(Reply to T. C. W.)—The liquid products—naphtha, benzole, phenols, &c.—are tested by fractional distillation, observing the proportions by volume passing over between certain temperatures, and in the case of phenol observing also the proportion crystallising, and taking the melting-point of this. These test-proportions, the temperatures at which they shall pass over, and in the case of phenol the melting-point, are usually fixed by the trade contract. I know no book containing an account of the methods, which are simple cases of fractional distillation. Information on the testing of anthracen and the other solid products, as also of the aniline colours, &c., will be found usefully given in Bolley and Kopp's "Manuel Pratique d'Essais et de Recherches Chimiques Appliquées aux Arts et à l'Industrie." Paris: F. Savy, 24, Rue Hautefeuille.—WATSON SMITH, F.C.S., F.I.C.

MEETINGS FOR THE WEEK.

MONDAY, 21st.—Medical, 8.30.
Society of Arts, 8. "Recent Advances in Telegraphy," by W. H. Preece. (Cantor Lectures.)

TUESDAY, 22nd.—Civil Engineers, 8.
Royal Institution, 3. "Schubert," by Mr. Ernst Pauer.

WEDNESDAY, 23rd.—Society of Arts, 8. "English Fresh-water Fisheries," by J. Willis-Bund.

THURSDAY, 24th.—Royal, 8.30.
Royal Institution, 3. "Dissociation," by Prof. Dewar.

FRIDAY, 25th.—Royal Society Club, 6.30.
Royal Institution, 9. "Generic Images," by Mr. Francis Galton.

FRIDAY, 25th.—Quekett, 8.
Royal Institution, 3. "Architecture," by Mr. H. H. Statham.

PHYSICAL, 3.—"On Selective Reflection," by Capt. Abney. "On some Phenomena Connected with Magneto-electric Induction," by C. Boys. "Notes from the Physical Laboratory of University College, Bristol," by Dr. S. P. Thompson.

ORGANIC MATERIA MEDICA.
By DR. MÜTER.

Analytical Chemists will find this a concise and yet complete book of reference for the isolation and examination of the active principles of drugs. Special appendix on the microscopic characters of the starches in food and drugs. Copious index and qualitative courses or resins, &c.

Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, S.E., and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of
Woolen Shoddy; free from grease; containing nitrogen
equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and
Co., Clayton, near Manchester.

The Advertiser, with considerable practical
experience as Sugar and Brewing Chemist, is wishing to meet
a position where his knowledge would prove of service. High testi-
monials and references.—Address, M. N. T., CHEMICAL NEWS Office,
Boy Court, Ludgate Hill, London, E.C.

Wanted as Assistant in a Laboratory, a young
gentleman, having a fair knowledge of General and Analytical
Chemistry. A small salary will be given. Apply to "Public Analyst,"
CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

LAND AND WORKS TO LET.—Suitable
for Chemical Works, Paper Works, Iron, Tin, or Copper Works,
or any Works producing noxious smoke. Rent moderate. Coal of
every description abundant from 4s. per ton. Good supply of water.
Building stones plentiful. Canal and Railway communication with
Swansea and Neath Harbour. Apply to Richard Hall and Sons, 37,
Great George Street, Westminster, and Mr. Thomas Williams,
Aberdulais, Neath, Glamorganshire.

Silicates of Soda and Potash in the state of
Soluble glass, or in CONCENTRATED SOLUTION of first
quality, suited for the manufacture of Soap and other purposes,
supplied on best terms by W. GOSSAGE and Sons, Soap
Works, Widnes, Lancashire.
London Agents, COSTE and Co., 19 and 20, Water Lane, Tower
street, E.C., who hold stock ready for delivery.

DR. LUNGE'S NITROMETER.

This Apparatus, for the Determination of
Nitrous and Nitric Acids, as described in CHEMICAL NEWS of
July 12th, can now be supplied. Absorption Apparatus for Oxygen
Estimation now ready. Particulars on application

MAWSON and SWAN Newcastle-on-Tyne.

Vol. XXIX. No. 1013.

THE PREPARATION IN A STATE OF PURITY
OF THE GROUP OF METALS
KNOWN AS THE PLATINUM SERIES,
AND NOTES UPON
THE MANUFACTURE OF IRIDIO-PLATINUM.*

By GEORGE MATTHEY.

IN this paper it is not my intention, nor should I be able, to refer generally to the results of work in the various branches of platinum metallurgy carried out by my firm, who, as is well known, have been associated with the development of this special field of industry from its earliest infancy; but I shall confine myself simply to that section of it upon which my personal attention has of late years been specifically concentrated in order to meet and comply with the requisition of the Bureau Internationale des Poids et Mesures, the Section Française de la Commission Internationale du Mètre, and of l'Association Géodésique Internationale (all of them important scientific committees, formed with the object of arriving at an accurate and definite solution of the long agitated question of standard weights and measures), and also at the demand of the French Minister of War, for an alloy the best adapted for the manufacture of the international metre and kilogram standard, and the geodesique rule; and in my endeavour to solve this difficult problem I have had the great advantage of being able to consult those distinguished men, MM. Henri Sainte-Claire Deville and Henri Debray, of Paris, and have also had the benefit of the excellent and valued advice of M. Stas, the celebrated Belgian chemist, to all of whom the scientific world owe so much, and to whom I desire to offer my warmest thanks.

In a paper of this kind it would be superfluous for me to enter into any of the already published details concerning the existence and collection of what is known as platinum-dust or mineral. It is sufficient for me to observe that the six metals (of which platinum is the chief) usually found more or less in association in their native state, present characteristics of interest beyond their metallurgical utility, which are, perhaps, worth alluding to *en passant*. It is, for instance, a curious fact that the group should consist of three light and three heavy metals, each division being of approximately the same specific gravity—the heavier being (in round figures) just double the density of the lighter series.

Thus we find osmium, iridium, platinum forming the first division, of the respective specific gravities of 22.43, 22.39, 21.46; whilst ruthenium, rhodium, and palladium are represented by the figures 11.40, 11.36, 11, the average densities of the heavy and light divisions thus being respectively 22.43 and 11.25.

But a more interesting and important classification is what I may designate as a first and second class series, from the more important view of their relative properties of stability. Thus platinum, palladium, and rhodium form the first or higher class, not being volatilisable in a state of oxide; iridium, osmium, and ruthenium forming the second or lower class, their oxides being more or less readily volatilised.

The oxide of iridium is effected at 700° to 800° C., and entirely decomposed at 1000°, whilst osmic and hyporuthenic acids are volatilised at the low degree of 100°, the latter exploding at 108°. The chlorides of these metals can be sublimed at different temperatures (as also the protochloride of platinum).

I now propose to give a short description of the methods I have employed for preparing the pure platinum and iridium necessary for the manufacture of the alloy, which I call "iridio-platinum," and it is upon the distinguishing characteristics above-mentioned that my method of separation is chiefly founded.

Platinum.

The preparation of this metal to a state of purity is an operation of extreme delicacy. I commence by taking ordinary commercial platinum; I melt this with six times its weight of lead of ascertained purity, and, after granulation, dissolve slowly in nitric acid diluted in the proportion of 1 volume to 8 of distilled water. The more readily to ensure dissolution, it is well to place the granulated alloy in porcelain baskets such as are used in the manufacture of chlorine gas for holding the oxide of manganese. When the first charge of acid is sufficiently saturated, a fresh quantity should be added until no more action is apparent; at this stage the greater part of the lead will have been dissolved out together with a portion of any copper, iron, palladium, or rhodium that may have been present. These metals are subsequently extracted from the mother-liquors, the nitrate of lead by crystallisation, and the remaining metals by well-known methods.

The metallic residue now obtained will be found in the state of an amorphous black powder (a form most suitable for further treatment), consisting of platinum, lead, and small proportions of the other metals originally present—the iridium existing as a brilliant crystalline substance insoluble in nitric acid. After digesting this compound in weak aqua regia, an immediate dissolution takes place of the platinum and lead, leaving the iridium still impure, but effecting a complete separation of the platinum.

To the chloride of platinum and lead after evaporation is added sufficient sulphuric acid to effect the precipitation of the whole of the lead as a sulphate, and the chloride of platinum after dissolution in distilled water is treated with an excess of chloride of ammonium and sodium, the excess being necessary in order that the precipitated yellow double salt may remain in a saturated solution of the precipitant. The whole is then heated to about 80°, and allowed to stand for some days; the ammonio-chloride of platinum will settle down as a firm deposit at the bottom of the vessel, whilst if any rhodium, as is generally the case, is present, the surface liquor will be coloured a rose tint, occasioned by a combination of the salts of the two metals.

The precipitate must be repeatedly washed with a saturated solution of chloride of ammonium and subsequently with distilled water charged with pure hydrochloric acid. This is necessary for its purification. The small quantity of the double salt which will be taken up and held in solution is of course recovered afterwards. Rhodium may still exist in the washed precipitate, which must therefore not be reduced to the metallic state until its separation is completed, and this is best effected by mixing with the dried compound, salts of chloro-platinate and chloro-rhodate of ammonia, bisulphate of potash with a small proportion of bisulphate of ammonia, and subjecting to a gradual heat brought by degrees up to a dull red in a platinum capsule, over which is placed an inverted glass funnel. The platinum is thus slowly reduced to a black spongy porous condition free from water, nitrogen, sulphate of ammonia, and hydrochloric acid, the rhodium remaining in a soluble state as bisulphate of rhodium and potash, which can be dissolved out completely by digesting in boiling distilled water; a small quantity of platinum will have been taken up in a state of sulphate, but is regained by heating the residue (obtained on evaporation) to redness, at which heat it is reduced to the metallic condition, the rhodium salt remaining undecomposed.

By the method above described the platinum is freed not only from rhodium, but from all other metals with which it may have been contaminated, and is brought to

* A Paper read before the Royal Society.

a state of absolute purity, of the density 21.46, the highest degree obtainable.

Iridium.

In the preparation of this metal when intended to be used for the manufacture of iridio-platinum alloy, I have arrived at freeing it to the utmost possible extent from all its associate metals, except platinum, disregarding the presence of the latter; the proportion of which, once determined, would only form matter of calculation in the final operation of mixing my alloy.

In practice, the purest iridium which can be obtained from its ordinary solution (deprived of osmium by long boiling in aqua regia and precipitated by chloride of ammonium) will almost invariably contain traces of platinum, rhodium, ruthenium, and iron.

I fuse such iridium in a fine state of division with ten times its weight of lead, keeping it in a molten state for some hours, dissolve out the lead with nitric acid, subject the residue to a prolonged digestion in aqua regia, and obtain a crystalline mass composed of iridium, rhodium, ruthenium, and iron, in a condition suitable for my further treatment. By fusion at a high temperature with an admixture of bisulphate of potash, the rhodium is almost entirely removed, any remaining trace being taken up together with the iron in a later operation. The iridium so far prepared is melted with ten times its weight of dry caustic potash, and three times its weight of nitre, in a gold pan or crucible; the process being prolonged for a considerable time to effect the complete transformation of the material into iridiate and ruthenate of potash, and the oxidation of the iron; when cold, the mixture is treated with cold distilled water. The iridiate of potash of a blue tinge will remain as a deposit almost insoluble in water, more especially if slightly alkaline, and also the oxide of iron.

This precipitate must be well washed with water charged with a little potash and hypochlorite of soda until the washings are no longer coloured, and then several times with distilled water.

The blue powder is then mixed with water strongly charged with hypochlorite of soda, and allowed to remain for a time cold, then warmed in a distilling vessel, and finally brought up to boiling-point until the distillate no longer colours red, weak alcohol acidulated with hydrochloric acid.

The residue is again heated with nitre and potash water charged with hypochlorite of soda and chlorine, until the last trace of ruthenium has disappeared.

Further, to carry out the purification, the blue powder (oxide of iridium) is re-dissolved in aqua regia, evaporated to dryness, re-dissolved in water, and filtered.

The dark-coloured solution thus obtained is slowly poured into a concentrated solution of soda and mixed with hypochlorite of soda, and should remain as a clear solution without any perceptible precipitate, and subjected in a distilling apparatus to a stream of chlorine gas, should not show a trace of ruthenium when hydrochloric acid and alcohol are introduced into the receiver. In this operation the chlorine precipitates the greater part of the iridium in a state of blue oxide, which after being collected, washed, and dried, is placed in a porcelain or glass tube, and subjected to the combined action of oxide of carbon and carbonic acid obtained by means of a mixture of oxalic with sulphuric acid gently heated.

The oxide of iridium is reduced by the action of the gas leaving the oxide of iron intact, the mass is then heated to redness with bisulphate of potash (which will take up the iron and any remaining trace of rhodium), and after subjecting it to many washings with distilled water, the residue is washed with chlorine water to remove any trace of gold, and finally with hydrofluoric acid, in order to take out any silica which might have been accidentally introduced with the alkalis employed or have come off the vessels used.

The iridium, after calcination at a strong heat in a

charcoal crucible, is melted into an ingot, and after being broken up and boiled in hydrochloric acid, to remove any possible trace of iron adhering to it through the abrasion in breaking up, should possess if perfectly pure a density of 22.39; but, as iridium prepared even with the utmost care will still contain minute though almost inappreciable traces of oxygen, ruthenium, rhodium, and possibly iron, the highest density I have yet attained is 22.38.

Alloy of Iridio-Platinum.

This compound metal possesses physical properties of great value, forming a beautiful example of the effect of a careful combination of the opposite characteristics of its component parts. Thus, the extreme softness and expansiveness of pure platinum and the brittleness and excessive hardness of pure iridium, produce, by combination in judicious proportions, a perfect and homogeneous alloy, possessing the necessary mean of these properties to render it suitable for many important purposes, amongst others that of the special object to be attained to meet the requirements for an unalterable standard metal, for which it is peculiarly adapted.

In the manufacture of the prototype metres and the geodesique rules (each 4 metres in length) ordered from my firm by the Comité Internationale des Poids et Mesures, the Association Geodesique Internationale, and the French Minister of War, I proceeded in the following manner with the platinum and iridium prepared as described above.

Operating upon a charge of 450 ounces of platinum and 55 ounces of iridium, I commenced by melting these metals together and casting into an ingot of suitable shape, which I then cut into small pieces with hydraulic machinery. After re-melting and retaining in a molten condition under a powerful blast of oxygen and common gas for a considerable time, I re-cast and forged at an intense white heat under a steam hammer, the highly polished surfaces of which were cleaned and polished after each series of blows—when sufficiently reduced it was passed through bright polished steel rollers, cut into narrow strips, and again slowly melted in a properly shaped mould, in which it was allowed to cool. I thus obtained a mass of suitable shape for forging, perfectly solid, homogeneous, free from fissures or air-holes, and with a bright and clean surface at bottom and sides as at top. At the first forging a bar was obtained 35 centims. long, 7.5 wide, 2.5 thick, which weighed—

In air		15.105 grms.
In water at 70° F.		14.405 "
Showing a density at zero of	21.522	

A third of the bar was cut off and the larger portion again forged to a length of 95 centims., width 2.5, thickness 2.0, which weighed—

In air		10.814 grms.
In water at 60° F.		10.315 "
Showing a density at zero of	21.648	

This was then passed through highly polished rolls until of a length of 4080 centims., 21 millims. in width, and 5 millims. thick, to which a perfectly rectangular form was subsequently given by drawing it through a series of plates, and thus prepared the rule was in a condition to receive the beautiful polish of which this alloy is susceptible.

After passing it through each hole the metal was annealed by means of a jet of gas and oxygen to a heat just below melting-point, and each time throughout after forging, rolling, and drawing was exposed to the action of melted borax, and boiled in concentrated hydrochloric acid to remove any possible trace of adherent iron or other impurity.

A piece cut from the end and presented to the French Academy of Sciences gave the following results:—

Weight in air		116.898 grms.
" water		111.469 "
Showing a density of		21.516

thus proving that the necessary processes of annealing at a high temperature had caused it sensibly to resume its original density.

The analysis gave—

	I.	II.
Platinum	89'40	89'42
Iridium	10'16	10'22
Rhodium	0'18	0'16

thus coinciding perfectly with the practical results obtained.

Messrs. Leon Brunner Brothers, of Paris, who had submitted this material of the geodesique rule to a great number of mechanical experiments, communicated the result of their observations to M. H. Sainte-Claire Deville, thus:—

" Paris, 27 Août, 1878.

"MONSIEUR,

« La division de la règle géodésique, que nous faisons pour l'Association Géodésique Internationale, est terminée depuis quelques jours.

« Nous avons pensé que vous ne seriez pas mécontent d'apprendre que cette opération à parfaitement réussi, et que c'est au métal que nous attribuons la facilité avec laquelle nous avons pu l'exécuter.

« La platine irridie de M. Matthey est incontestablement supérieure au platine ordinaire, pour la confection de règles divisées. Il est exempt de ces pailles qu'on rencontre toujours dans ce dernier, et se laisse polir au charbon. On peut, sans danger, enlever les rébarbes des traits et les conserver très beaux. Le platine ordinaire ne peut-être poli qu'au papier à émeré, et l'on est toujours exposé à gâter la division quand on procède à l'ébarbage. C'est là un inconvénient très-grave.

"Nous ne pouvons que vous remercier, Monsieur, d'avoir mis à notre disposition un métal qui modifie singulièrement les difficultés qu'on rencontre dans la fabrication d'une règle géodésique, et nous vous prions de recevoir l'assurance de nos sentiments les plus distingués."

"BRUNNER FRERES.

In the year 1876 the suggestion was made to supersede the rectangular form by a tubular one, and I was requested to produce one of the following dimensions:—Length, 1002 centims.; exterior diameter, 37 millims.; interior diameter, 35 millims.; with rounded ends, one having an extension of small tube 4 millims. exterior diameter, 2 millims. interior diameter, 40 millims. long, which I did by the system of tube-making with automatic joints adopted by me with excellent results for the last twenty years, employing for the purpose an alloy prepared as above described. These proved to be so satisfactory that I have since made others, both round and square, of various dimensions, as lately shown at the Paris Exhibition.

Indio-platinum alloy has now been proved to possess the following among many advantages for standard rules and weights :—

It is almost indestructible, has extreme rigidity, especially in the tube form, and a most beautifully polished surface can be obtained upon it; its coefficient of elasticity is very great, whilst for standard weights its high density

is a valuable quality, and for these I should indeed recommend an alloy of not less than 20 per cent of iridium. I lately made at the request of M. H. Sainte-Claire Deville a cylinder 40 millims. by 40 millims. of such an alloy, which showed by analysis the following proportions:—

Platinum	..	..	..	..	80°6600
Iridium	..	..	..	..	19°0786
Rhodium	..	..	..	..	0°1220
Ruthenium	..	..	..	..	0°0460
Iron	..	..	..	..	0°0080

100'0046

and gave the density of 21.614.

With such a high density its coefficient of elasticity is 22·200000, one of the highest known, whilst its malleability and ductility are almost without limit.

The volume of the kilogram thus prepared is only 46266 c.c., it displaces 2267 c.c. less than the kilogram of the archives of France, and on this account, as on many others, is of course preferable.

The results I have arrived at in preparing alloys of higher grades, viz., 25, 30, 40, and 50 per cent of iridium, are as follows:—

The alloy of 20 per cent iridium is, as I have stated already, malleable and ductile.

25 per cent can only with great difficulty and waste be worked into sheet and wire when heated at low temperature. 30 per cent and 40 per cent with great difficulty only at a temperature little less than melting-point, being brittle when cold, but with a grain of great beauty and fineness.

50 per cent I have as yet failed to work up into forms other than castings beyond what I can effect by pressure when in a semi-fused condition.

The general results of my work on this alloy would lead me, therefore, to make the following recommendations.

For the manufacture of standard rules to use an alloy of not less than 85 per cent platinum and 15 per cent iridium, adopting the tubular form.

For the standard weights to use an alloy of not less than 80 per cent platinum and 20 per cent iridium, adopting the form now generally made.

Finally, following the expression of the great French chemist, M. Dumas, I hope by these labours "d'avoir enrichi l'outillage scientifique d'un alliage doué des propriétés précieuses."

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

By Professor ABEL, C.B., F.R.S.

(Continued from p. 166.)

It has been stated that detonation can be transmitted from one mass of gun-cotton or dynamite to another through intervening air-spaces. The extent to which such spaces can be introduced without checking detonation is obviously regulated by the size of the masses of explosive detonated; but the distance of air-space through which the detonation of a moderate quantity of the explosive agent will communicate to similar masses are very limited, a space of 2 inches being sufficient to prevent the detonation produced by a mass of 8 ozs. of gun-cotton, freely exposed, from communicating to contiguous ones. If the dispersion of the force is prevented in part, and direction is given to the gases violently projected from the centre of detonation, the power of transmitting detonation to separated masses of explosive is increased to a remarkable degree. This is readily accomplished through the agency of tubes, the charge first detonated being just inserted

* Abstract of a Paper read before the Royal Institution of Great Britain, Friday, March 21, 1879.

into one extremity, while that to which the detonation is to be transmitted is inserted into the other; or separate charges may be placed at different distances inside a long tube, with long intervening spaces, the initiative charge being inserted at one end. A few illustrations of the results thus obtained may be given. The detonation of a 1-oz. disk of gun-cotton in the open air will not transmit detonation with *certainty* to other disks placed at a greater distance than half an inch from it; but if it be just inserted into one of an iron tube 2 feet long and 1.25 inch in diameter, a similar disk, or even a plug of loose gun-cotton, inserted into the other extremity of the tube, will invariably be detonated. With employment of 2 ozs. of gun-cotton, in a tube of the same material, thickness, and diameter, detonation was transmitted to a distance of 5 feet. In tubes of the same kind, of very considerable length, 2-oz. disks of gun-cotton, placed at intervals of 2 feet, were detonated through the initiative detonation of one such disk inserted into one extremity of the tube. In other experiments a long tube of this kind was fitted with branch pipes, 2 feet long, at those parts where the intermediate disks were placed, and charges of gun-cotton were placed at the extremities of these pipes. By the initiative detonation of 1 oz. of gun-cotton all the charges were detonated, the effect on the air being that of one single explosion. The results obtained with equal quantities of gun-cotton varied with the diameter, strength, and nature of the material of the tubes used. Dynamite and mercuric fulminate, applied to their own detonation, furnished results quite analogous to those obtained with gun-cotton; but in applying fulminate to the detonation of gun-cotton through the agency of tubes, some singular and instructive results were obtained, for an account of which the lecturer referred to his Memoir on this subject.

Silver fulminate was employed for the purpose of instituting more precise experiments than could be made in operating on a larger scale, with gun-cotton, on the influence of the material composing the tubes, of the condition of their inner surfaces, and other variable circumstances, upon the transmission of detonation. Half a grain of silver fulminate, freely exposed and ignited by a heated body, will transmit detonation to some of the compound placed at a distance of 3 inches from it, but does not do so with certainty through a distance of 4 inches. But when the quantity of the fulminate is just inserted into one end of a stout glass tube, 0.5 inch in diameter and 3 feet long, its detonation is invariably induced by that of a similar quantity of the fulminate placed just inside the other extremity of the tube; this result is uncertain when the length of the tubes of the same thickness and diameter exceeds 3 feet 3 inches. Glass tubes were found to transmit the detonation of silver fulminate much more rapidly than tubes of several other materials of the same diameter and thickness of substance. Thus, with the employment of double the quantity of fulminate required to transmit the detonation with certainty through a glass tube of the kind described, 3 feet in length, it was only possible to obtain a similar result through a pewter tube 31.5 inches long, a brass tube 23.7 inches long, an india-rubber tube 15.8 inches long, and a paper tube 11.8 inches long. The difference in the results obtained was not ascribable to a difference in the escape of force on the instant of detonation, in consequence of the fracture of the tube, nor to the expenditure of force in work done upon the tube at the seat of detonation, since the glass tubes were always destroyed by the first explosion to a much greater distance along their length than any of the others, and the brass tubes, which were in no way injured at the seat of explosion, did not transmit detonation to so great a distance as the pewter tubes, which were always deeply indented. The transmission of detonation appeared, also, not to be favoured by the sonorosity or the pitch of the tube employed, as the sonorous brass tube was not found to favour the transmission to the same extent as the pewter tube. Moreover, the transmission of detonation by the glass tubes was not found to be at all affected by coating these

tubes with several layers of paper, or by encasing them in tightly-fitting india-rubber tubes. These differences appeared on further investigation not to be ascribable, to any important extent, if at all, to the difference in the nature of the material composing the tubes, but to be simply, or at any rate almost entirely, due to differences in the condition of the inner surfaces of the tubes. Thus, brass tubes, the inner surfaces of which were highly polished, and paper tubes, when coated inside with highly glazed paper, transmitted the detonation of the silver fulminate to about the same distance as the glass tubes; on the other hand, when the inner surfaces of the latter were slightly roughened by coating them with a film of fine powder, such as French chalk, they no longer transmitted detonation to anything like the distance which they did when the inner surfaces were in the normally smooth condition. Other very slight obstacles to the unimpeded passage of the gas-wave through the tubes were found greatly to reduce the facility with which detonation could be transmitted by means of tubes. Thus, when a diaphragm of thin bibulous paper was inserted into the glass tube about half-way between the two extremities, detonation was not transmitted, even with the employment of about six times the quantity of fulminate that gave the result with certainty under ordinary conditions; and, similarly, the transmission of detonation by increased charges of mercuric fulminate and of gun-cotton was prevented by the introduction into the tubes of light tufts of carded cotton-wool just sufficient in quantity to shut out the light in looking through the tubes.

Among several other interesting results furnished by an examination into the conditions governing and results attending the transmission of detonation by tubes, a remarkable want of reciprocity was found to exist between mercuric fulminate and gun-cotton. The latter substance is more susceptible to the detonative power of mercuric fulminate than of any other substance, as will presently be further shown. The quality of fulminate required to detonate gun-cotton is regulated by the degree to which the sharpness of its own detonation is increased by the amount of resistance to rupture offered by the envelope in which the fulminate is confined. From 20 to 30 grains are required if the detonative agent is confined in a thin case of wood or in several wrappings of paper; but as small a quantity as 2 grains of the fulminate suffices to effect the detonation of compressed gun-cotton, provided the fulminate be confined in a case of stout metal (sheet tin), and be closely surrounded by being tightly imbedded in the mass of gun-cotton. If there be no close contact between the two, the quantity of fulminate must be very considerably increased to ensure the detonation of the gun-cotton; and, in attempting to transmit detonation from mercuric fulminate to gun-cotton by means of tubes, it was found necessary to employ comparatively very large quantities of fulminate in order to accomplish this, even through short lengths of tubes. But when the quantity of fulminate used reaches certain limits, the detonation may be transmitted from it to gun-cotton through very long lengths of tube. In applying gun-cotton, on the other hand, to accomplish the detonation of mercuric fulminate, it was found that this result could be attained, and through considerable lengths of tube (7 feet and upwards), by means of very much smaller quantities of gun-cotton than is needed of fulminate to induce the detonation of gun-cotton through the corresponding distances.

This want of reciprocity between two detonating agents corresponds to one even more remarkable, which was observed by the lecturer in his earlier investigations on this subject. In the first place it was found that the detonation of $\frac{1}{2}$ oz. of gun-cotton (the smallest quantity that can be thus applied) induced the simultaneous detonation of nitro-glycerin, enclosed in a vessel of sheet-tin, and placed at a distance of 1 inch from the gun-cotton; while with $\frac{1}{2}$ oz. of the latter the same effect was produced with an intervening space of 3 inches between the two substances. But on attempting to apply nitro-glycerin to

of gun-cotton, the quantity of the former, detonated in close contact with compressed was gradually increased in the first instance subsequently even to 2 ozs., without accommodation of the latter, which was simply a fine state of division, in all instances but one, number of experiments.

developed by the detonation of nitro-glycerin by careful comparison of the relative destruction of corresponding quantities, to be decidedly that of the fulminate, of which from 2 to 5 is for developing the detonation of gun-cotton, in close contact with them. The non-susceptibility of cotton to detonation by nitro-glycerin is need scarcely be said, not ascribable to any mechanical force suddenly applied when the is detonated.

lower possessed by different very highly explosives, of inducing the detonation of such bodies and nitro-glycerin is not solely ascribable to a of mechanical force very suddenly developed, not only by the singular inertness of gun-influence of nitro-glycerin as a detonating also by a comparison of the behaviour of other substances with that of the mercuric fulminate, d to the detonation of gun-cotton. Thus, the of silver fulminate is very decidedly sharper the mercury compound, yet it is in no way be latter in its power as an initiative detonant; indeed, a somewhat larger amount of it be required than of the mercury salt to induce of gun-cotton with certainty. Again, the chloride of nitrogen are far more susceptible of action than the silver fulminate; yet while be latter, confined in a stout metal envelope, stonate gun-cotton, 50 grains of chloride of fined by water, appeared to be the minimum i which the detonation of gun-cotton could be d with certainty, while no success attended sent of confined iodide of nitrogen in quantity up to 100 grains.

compatibility of these results with the general based upon numerous and greatly varied experiments the facility with which the detonation of and nitro-glycerin, and bodies of a similar explosives, is induced by an initiative detonation to the mechanical force aided by the ed by the latter, led the lecturer to the conclusion of synchronism or similarity in character or quality ions developed by the detonation of particular operates in favouring the detonation of one nce by the initiative detonation of a small another, while in the absence of such synchronism more powerful detonation, or the application ster force, would be needed to effect the detonation material operated upon. This view has siderable support from results since obtained erimenters, especially by M.M. Champion and the subject is one which still needs further excitation.

(To be continued.)

NEW VOLUMETRIC METHOD OF DETERMINING FLUORINE.

By SAMUEL L. PENFIELD,
Assistant in the Sheffield Laboratory.

is the well-known reaction—

f a volumetric determination of fluorine, be quantity of hydro-fluosilicic acid formed weight of a fluoride by means of a standard B.]

It is impossible to titrate the hydro-fluosilicic acid directly, because as soon as an alkaline reaction is reached the silico-fluoride is decomposed and an acid reaction is indicated, which change goes on slowly. But when barium chloride and an equal volume of alcohol are added to the solution, barium silico-fluoride is precipitated from the solution, and an equivalent amount of hydrochloric acid is liberated, which can be titrated; by this means, using litmus as an indicator, I was enabled to get some very satisfactory results, but the turbidity caused by the barium silico-fluoride interfered with the change of colour of the litmus, and cochineal I was not able to use at all.

On further experimenting I found that potassium chloride possessed some advantages over barium chloride. On adding potassium chloride and an equal volume of alcohol, potassium silico-fluoride is precipitated from the solution, and an equivalent of hydrochloric acid is liberated, but the potassium silico-fluoride is a very transparent precipitate, and does not interfere with the change of colour of the indicators. It is necessary that alcohol shall make up at least one-half the volume of the liquid to be titrated, so as to precipitate the potassium silico-fluoride as completely as possible.

The apparatus needed is very simple, and consists of a gasometer of ten or more litres capacity, a few flasks of about 150 c.c. capacity, a few large plain U-tubes 18 centimetres long and 2½ centimetres diameter, made without any narrowing in the bend, and a heavy iron plate supported properly so that it may be heated with a lamp.

The fluoride is weighed out accurately into one of the flasks; unless it is a silicate, 10 grms. of powdered and ignited quartz are added, and two or three pieces of quartz about the size of kidney beans. These last facilitate mixing up the powder when the flask is shaken. The contents of the flask are then drenched with from 30 to 40 c.c. of sulphuric acid which has been previously heated and allowed to cool. The flask is tightly closed with a doubly perforated cork; from the gasometer dry air is passed into the flask by means of a glass tube which reaches nearly to the bottom. The silicon fluoride mixed with air passes from the decomposing flask first through a small U-tube, made from ordinary glass tubing, 5 millimetres in diameter, and kept cool by being placed in a beaker of cold water, then into one of the large U-tubes intended for decomposing the silicon fluoride and absorbing the hydro-fluosilicic acid. The U-tube contains a solution of potassium chloride mixed with an equal volume of alcohol; the escaping gas is made to bubble through this, and to ensure complete decomposition a second smaller U-tube is attached to the first: the first tube absorbs nearly all the acid, the second contains only traces. The decomposing flask is supported on the iron plate; by its side is placed a second flask containing sulphuric acid and a thermometer supported so that its bulb dips into the acid; the lamp heating the plate is placed midway between the flasks, and the heat is regulated so that the temperature of the acid remains between 150° and 160° C.

The decomposition is continued two hours in ordinary cases, and during that time a continuous current of air is forced through the apparatus, amounting to from 5 to 6 litres for the two hours, while the contents of the decomposing flask are frequently agitated by shaking.

After the decomposition and aspiration are completed the contents of the U-tubes are titrated. For this purpose they may be transferred to a beaker, the tubes being rinsed with alcohol and water, or better, the acid may be titrated directly in the U-tubes. In order that the alcohol may make up one-half the volume of the liquid after the titration is completed, add a few c.c. of alcohol before titrating, or where 15 or more c.c. are to be added use a standard alkali one-half of whose volume is alcohol. A the separated silicic acid sticks to the sides of the U-tube it is necessary to have prepared a glass rod bent a little at one end to scrape off and break up this silica,

into one extremity, while that to which the detonation is to be transmitted is inserted into the other; or separate charges may be placed at different distances inside a long tube, with long intervening spaces, the initiative charge being inserted at one end. A few illustrations of the results thus obtained may be given. The detonation of a 1-oz. disk of gun-cotton in the open air will not transmit detonation with *certainty* to other disks placed at a greater distance than half an inch from it; but if it be just inserted into one of an iron tube 2 feet long and 1.25 inch in diameter, a similar disk, or even a plug of loose gun-cotton, inserted into the other extremity of the tube, will invariably be detonated. With employment of 2 ozs. of gun-cotton, in a tube of the same material, thickness, and diameter, detonation was transmitted to a distance of 5 feet. In tubes of the same kind, of very considerable length, 2-oz. disks of gun-cotton, placed at intervals of 2 feet, were detonated through the initiative detonation of one such disk inserted into one extremity of the tube. In other experiments a long tube of this kind was fitted with branch pipes, 2 feet long, at those parts where the intermediate disks were placed, and charges of gun-cotton were placed at the extremities of these pipes. By the initiative detonation of 1 oz. of gun-cotton all the charges were detonated, the effect on the air being that of one single explosion. The results obtained with equal quantities of gun-cotton varied with the diameter, strength, and nature of the material of the tubes used. Dynamite and mercuric fulminate, applied to their own detonation, furnished results quite analogous to those obtained with gun-cotton; but in applying fulminate to the detonation of gun-cotton through the agency of tubes, some singular and instructive results were obtained, for an account of which the lecturer referred to his Memoir on this subject.

Silver fulminate was employed for the purpose of instituting more precise experiments than could be made in operating on a larger scale, with gun-cotton, on the influence of the material composing the tubes, of the condition of their inner surfaces, and other variable circumstances, upon the transmission of detonation. Half a grain of silver fulminate, freely exposed and ignited by a heated body, will transmit detonation to some of the compound placed at a distance of 3 inches from it, but does not do so with certainty through a distance of 4 inches. But when the quantity of the fulminate is just inserted into one end of a stout glass tube, 0.5 inch in diameter and 3 feet long, its detonation is invariably induced by that of a similar quantity of the fulminate placed just inside the other extremity of the tube; this result is uncertain when the length of the tubes of the same thickness and diameter exceeds 3 feet 3 inches. Glass tubes were found to transmit the detonation of silver fulminate much more rapidly than tubes of several other materials of the same diameter and thickness of substance. Thus, with the employment of double the quantity of fulminate required to transmit the detonation with certainty through a glass tube of the kind described, 3 feet in length, it was only possible to obtain a similar result through a pewter tube 31.5 inches long, a brass tube 23.7 inches long, an india-rubber tube 15.8 inches long, and a paper tube 11.8 inches long. The difference in the results obtained was not ascribable to a difference in the escape of force on the instant of detonation, in consequence of the fracture of the tube, nor to the expenditure of force in work done upon the tube at the seat of detonation, since the glass tubes were always destroyed by the first explosion to a much greater distance along their length than any of the others, and the brass tubes, which were in no way injured at the seat of explosion, did not transmit detonation to so great a distance as the pewter tubes, which were always deeply indented. The transmission of detonation appeared, also, not to be favoured by the sonorosity or the pitch of the tube employed, as the sonorous brass tube was not found to favour the transmission to the same extent as the pewter tube. Moreover, the transmission of detonation by the glass tubes was not found to be at all affected by coating these

tubes with several layers of paper, or by encasing them in tightly-fitting india-rubber tubes. These differences appeared on further investigation not to be ascribable, to any important extent, if at all, to the difference in the nature of the material composing the tubes, but to be simply, or at any rate almost entirely, due to differences in the condition of the inner surfaces of the tubes. Thus, brass tubes, the inner surfaces of which were highly polished, and paper tubes, when coated inside with highly glazed paper, transmitted the detonation of the silver fulminate to about the same distance as the glass tubes; on the other hand, when the inner surfaces of the latter were slightly roughened by coating them with a film of fine powder, such as French chalk, they no longer transmitted detonation to anything like the distance which they did when the inner surfaces were in the normally smooth condition. Other very slight obstacles to the unimpeded passage of the gas-wave through the tubes were found greatly to reduce the facility with which detonation could be transmitted by means of tubes. Thus, when a diaphragm of thin bibulous paper was inserted into the glass tube about half-way between the two extremities, detonation was not transmitted, even with the employment of about six times the quantity of fulminate that gave the result with certainty under ordinary conditions; and, similarly, the transmission of detonation by increased charges of mercuric fulminate and of gun-cotton was prevented by the introduction into the tubes of light tufts of carded cotton-wool just sufficient in quantity to shut out the light in looking through the tubes.

Among several other interesting results furnished by an examination into the conditions governing and results attending the transmission of detonation by tubes, a remarkable want of reciprocity was found to exist between mercuric fulminate and gun-cotton. The latter substance is more susceptible to the detonative power of mercuric fulminate than of any other substance, as will presently be further shown. The quality of fulminate required to detonate gun-cotton is regulated by the degree to which the sharpness of its own detonation is increased by the amount of resistance to rupture offered by the envelope in which the fulminate is confined. From 20 to 30 grains are required if the detonative agent is confined in a thin case of wood or in several wrappings of paper; but as small a quantity as 2 grains of the fulminate suffices to effect the detonation of compressed, gun-cotton, provided the fulminate be confined in a case of stout metal (sheet tin), and be closely surrounded by being tightly imbedded in the mass of gun-cotton. If there be no close contact between the two, the quantity of fulminate must be very considerably increased to ensure the detonation of the gun-cotton; and, in attempting to transmit detonation from mercuric fulminate to gun-cotton by means of tubes, it was found necessary to employ comparatively very large quantities of fulminate in order to accomplish this, even through short lengths of tubes. But when the quantity of fulminate used reaches certain limits, the detonation may be transmitted from it to gun-cotton through very long lengths of tube. In applying gun-cotton, on the other hand, to accomplish the detonation of mercuric fulminate, it was found that this result could be attained, and through considerable lengths of tube (7 feet and upwards), by means of very much smaller quantities of gun-cotton than is needed of fulminate to induce the detonation of gun-cotton through the corresponding distances.

This want of reciprocity between two detonating agents corresponds to one even more remarkable, which was observed by the lecturer in his earlier investigations on this subject. In the first place it was found that the detonation of $\frac{1}{2}$ oz. of gun-cotton (the smallest quantity that can be thus applied) induced the simultaneous detonation of nitro-glycerin, enclosed in a vessel of sheet-tin, and placed at a distance of 1 inch from the gun-cotton; while with $\frac{1}{2}$ oz. of the latter the same effect was produced with an intervening space of 3 inches between the two substances. But on attempting to apply nitro-glycerin to

the detonation of gun-cotton, the quantity of the former, which was detonated in *close contact* with compressed gun-cotton, was gradually increased in the first instance to $\frac{1}{2}$ oz., and subsequently even to 2 ozs., without accomplishing the detonation of the latter, which was simply dispersed in a fine state of division, in all instances but one, in a large number of experiments.

The force developed by the detonation of nitro-glycerin was found, by careful comparison of the relative destructive effects of corresponding quantities, to be decidedly greater than that of the fulminate, of which from 2 to 5 grains suffice for developing the detonation of gun-cotton, when it is in close contact with them. The non-susceptibility of gun-cotton to detonation by nitro-glycerin is therefore, it need scarcely be said, not ascribable to any deficiency in mechanical force suddenly applied when the nitro-glycerin is detonated.

That the power possessed by different very highly explosive substances, of inducing the detonation of such bodies as gun-cotton and nitro-glycerin is not solely ascribable to the operation of mechanical force very suddenly developed, is indicated not only by the singular inertness of gun-cotton to the influence of nitro-glycerin as a detonating agent, but also by a comparison of the behaviour of other detonating substances with that of the mercuric fulminate, when applied to the detonation of gun-cotton. Thus, the detonation of silver fulminate is very decidedly sharper than that of the mercury compound, yet it is in no way superior to the latter in its power as an initiative detonating agent; indeed, a somewhat larger amount of it appeared to be required than of the mercury salt to induce detonation of gun-cotton with certainty. Again, the iodide and chloride of nitrogen are far more susceptible of sudden detonation than the silver fulminate; yet while 5 grains of the latter, confined in a stout metal envelope, suffice to detonate gun-cotton, 50 grains of chloride of nitrogen confined by water, appeared to be the minimum amount with which the detonation of gun-cotton could be accomplished with certainty, while no success attended the employment of confined iodide of nitrogen in quantities ranging up to 100 grains.

The incompatibility of these results with the general conclusion, based upon numerous and greatly varied experiments, that the facility with which the detonation of gun-cotton and nitro-glycerin, and bodies of a similar character as explosives, is induced by an initiative detonation, is proportionate to the mechanical force aided by the heat developed by the latter, led the lecturer to the conclusion that a synchronism or similarity in character or quality of the vibrations developed by the detonation of particular substances, operates in favouring the detonation of one such substance by the initiative detonation of a small quantity of another, while in the absence of such synchronism, a much more powerful detonation, or the application of much greater force, would be needed to effect the detonation of the material operated upon. This view has received considerable support from results since obtained by other experimenters, especially by MM. Champion and Pellet; but the subject is one which still needs further experimental elucidation.

(To be continued.)

ON A NEW VOLUMETRIC METHOD OF DETERMINING FLUORINE.

By SAMUEL L. PENFIELD,
Assistant in the Sheffield Laboratory.

I HAVE made the well-known reaction—

as the basis of a volumetric determination of fluorine, estimating the quantity of hydro-fluosilicic acid formed from a given weight of a fluoride by means of a standard alkali solution,]

It is impossible to titrate the hydro-fluosilicic acid directly, because as soon as an alkaline reaction is reached the silico-fluoride is decomposed and an acid reaction is indicated, which change goes on slowly. But when barium chloride and an equal volume of alcohol are added to the solution, barium silico-fluoride is precipitated from the solution, and an equivalent amount of hydrochloric acid is liberated, which can be titrated; by this means, using litmus as an indicator, I was enabled to get some very satisfactory results, but the turbidity caused by the barium silico-fluoride interfered with the change of colour of the litmus, and cochineal I was not able to use at all.

On further experimenting I found that potassium chloride possessed some advantages over barium chloride. On adding potassium chloride and an equal volume of alcohol, potassium silico-fluoride is precipitated from the solution, and an equivalent of hydrochloric acid is liberated, but the potassium silico-fluoride is a very transparent precipitate, and does not interfere with the change of colour of the indicators. It is necessary that alcohol shall make up at least one-half the volume of the liquid to be titrated, so as to precipitate the potassium silico-fluoride as completely as possible.

The apparatus needed is very simple, and consists of a gasometer of ten or more litres capacity, a few flasks of about 150 c.c. capacity, a few large plain U-tubes 18 centimetres long and $2\frac{1}{2}$ centimetres diameter, made without any narrowing in the bend, and a heavy iron plate supported properly so that it may be heated with a lamp.

The fluoride is weighed out accurately into one of the flasks; unless it is a silicate, 10 grms. of powdered and ignited quartz are added, and two or three pieces of quartz about the size of kidney beans. These last facilitate mixing up the powder when the flask is shaken. The contents of the flask are then drenched with from 30 to 40 c.c. of sulphuric acid which has been previously heated and allowed to cool. The flask is tightly closed with a doubly perforated cork; from the gasometer dry air is passed into the flask by means of a glass tube which reaches nearly to the bottom. The silicon fluoride mixed with air passes from the decomposing flask first through a small U-tube, made from ordinary glass tubing, 5 millimetres in diameter, and kept cool by being placed in a beaker of cold water, then into one of the large U-tubes intended for decomposing the silicon fluoride and absorbing the hydro-fluosilicic acid. The U-tube contains a solution of potassium chloride mixed with an equal volume of alcohol; the escaping gas is made to bubble through this, and to ensure complete decomposition a second smaller U-tube is attached to the first: the first tube absorbs nearly all the acid, the second contains only traces. The decomposing flask is supported on the iron plate; by its side is placed a second flask containing sulphuric acid and a thermometer supported so that its bulb dips into the acid; the lamp heating the plate is placed midway between the flasks, and the heat is regulated so that the temperature of the acid remains between 150° and 160° C.

The decomposition is continued two hours in ordinary cases, and during that time a continuous current of air is forced through the apparatus, amounting to from 5 to 6 litres for the two hours, while the contents of the decomposing flask are frequently agitated by shaking.

After the decomposition and aspiration are completed the contents of the U-tubes are titrated. For this purpose they may be transferred to a beaker, the tubes being rinsed with alcohol and water, or better, the acid may be titrated directly in the U-tubes. In order that the alcohol may make up one-half the volume of the liquid after the titration is completed, add a few c.c. of alcohol before titrating, or where 15 or more c.c. are to be added use a standard alkali one-half of whose volume is alcohol. A standard alkali one-half of whose volume is alcohol. A separated silicic acid sticks to the sides of the U-tube it is necessary to have prepared a glass rod bent a little at one end to scrape off and break up this silica,

I have found by experiment that a simple dry U-tube between the decomposing flask and absorbing tube is sufficient to condense any sulphuric acid that may go over from the heated acid.

When fluorine is to be determined in a mineral containing chlorine, as in the case of an apatite, substitute for the empty U-tube one filled with fragments of pumice impregnated with perfectly anhydrous sulphate of copper. This will intercept any hydrochloric acid, and will also serve to condense any sulphuric acid vapour that may go over from the heated acid. The calculation is very simple. Every one equivalent of sodium carbonate equals one equivalent of hydro-fluosilicic acid or six of fluorine, hence the proportion—

Mol. wt. Na_2CO_3 : Mol. wt. 6F. Amt. of Na_2CO_3 : Amt. of F.
106 : 114 : : x

Below will be found some results which I have obtained from pure fluor-spar. The time of conducting the operation in every case was two hours, the amount of aspiration varied from $4\frac{1}{2}$ to $6\frac{1}{2}$ litres, and the indicator used was cochineal.

The first six were titrated with a dilute solution of ammonia, 1 c.c. of which equalled 0.0242 grm. of fluorine, the last four with a solution twice as strong and one-half of whose volume was alcohol.

SANITARY CONDITION OF AIR IN PUBLIC SCHOOLS.

By N. T. LUPTON, Vanderbilt University.

THE following series of determinations of carbon dioxide in air from the public schools of Nashville, Tennessee, was made at the request of the City Board of Health. The subject being one of general scientific interest, the results are submitted as a contribution to sanitary chemistry. (See Table on next page.)

The above observations were made each day at from 12.30 to 1.30 p.m., and from an hour and a half to two hours after recess. In a few instances, as indicated, two bottles of air were taken at the same time from one and the same room, but at different parts of the room. The results are connected by brackets. In making the determinations of carbon dioxide the well-known method of Pettenkofer was adopted, as it can be easily and rapidly performed, and gives accurate results.

Four thin white glass bottles, one of 4950, two of 3950, and one of 3925 c.c. capacity, were used. The bottles were filled with air from about the middle of the rooms while the schools were in session, by means of a small hand-bellows, and after standing a few minutes to equalise temperature and pressure, were closed with well-fitting caoutchouc stoppers. They were then taken to the open air, and exactly 50 c.c. of a solution of barium hydroxide rapidly run into each, the bottles closed, carried to the laboratory, and allowed to remain two or three hours with occasional shaking; or, rather, the solution was moved

about so as to moisten the interior surface of the and thus hasten the absorption of carbon dioxide. The milky-looking liquid was transferred to small mouthed, glass-stoppered bottles, and after the carbonate had settled, 25 c.c. of the supernatant were carefully titrated with a known solution of acid, turmeric paper being used to determine point of neutralisation. The solution of oxalic made of such strength that 1 c.c. corresponded to 10 of carbon dioxide.

For calculating the volume of carbon dioxide in volumes of air the following formula was used—

$$x = \frac{760(1 + 0.003665 \times t)p}{H(V - v)0.0019714}$$

in which H represents the height of the barometer in millimetres, V the capacity of the flask, v the volume of barium hydroxide solution used for absorption, t the temperature expressed in degrees of the Centigrade scale, p the amount in milligrams of carbon dioxide in the air experimented upon.

It will be seen from the tabular statement that the amount of carbon dioxide found in several instances as much as 25 volumes in 10,000, or one-quarter per cent. Whether this amount is sufficient to render air decidedly unwholesome may be questioned, though all will admit that an increase of six times the normal quantity found in the atmosphere shows imperfect ventilation. It was observed that in every case where the amount of carbon dioxide reached 20 in 10,000 or one-fifth of one per cent, the odour from other impurities of respiration was exceedingly offensive; and even where the amount was 10 in 10,000, offensive odour was distinctly perceptible.

While no reliable method has yet been devised for the direct determination of organic impurities resulting from respiration, recognisable by the sense of smell, and which vary with the amount of carbon dioxide in the air, and may thus be indirectly estimated.

In the construction of these school buildings, provision whatever was made for ventilation other than doors and windows, except some narrow flues in the buildings, and a ventilating-shaft at each of the corners of one other, with openings entirely too small to be of much service. The General Superintendent of schools, appreciating the importance of ventilation, established a rule which requires the teachers to leave the upper sash of each window a few inches open in the room opposite to that from which the wind may be blowing, so as to avoid draughts as much as possible during recess the windows are required to be raised, and the doors to be thrown open. It was evident from visits that these rules were faithfully carried out by the teachers, and that where defective ventilation existed, it was caused by defective construction of the room or overcrowding of pupils. It is a question of grave importance whether the return of children overheated by a cold room for the resumption of their studies is more dangerous to health than defective ventilation.

Opinions differ in regard to the quantity of air required per minute for one person for healthful respiration. Arnott says that 20 cubic feet are necessary; E. 10. Roscoe, in discussing certain experiments in school-rooms, says—"I have come to the conclusion that 10 cubic feet per minute per head is insufficient to move completely the organic putrescent matter in the air, calculating the amount of ventilation he uses the following expression:—

$$V^1 = V + Va + Va^2 + \dots + Va^n.$$

In which V^1 represents the volume of air to be supplied to produce a given amount of impurity, V the volume of air, and a the ratio between the natural impurity in the air (0.04) and that found in the room under examination. Roscoe determines only the first three terms of the

Carbonic Acid in 10,000 Volumes of Air.

but as it is an infinite decreasing series its exact value is—

$$V' = V \left(\frac{1}{1-a} \right).$$

To determine, then, the quantity of air in its normal condition which must be added to one of the rooms containing 136 pupils so as to give in one hour and a half the percentage of carbon dioxide (0.3242) found, we proceed as follows;—If one person exhales 0.686 cubic feet of this gas in one hour, 136 persons will exhale 139.944 cubic feet in one hour and a half. By a simple proportion we get the value of V, which, multiplied by the fraction in the equation whose terms are known, we get within reasonable limits the quantity of air with which 139.944 cubic feet of carbon dioxide must be mixed in order to make the percentage of this gas amount to 0.3242, the quantity actually found in the room. The calculation gives 49.242 cubic feet of air as necessary to reduce 139.944 cubic feet of carbon dioxide to 0.3242 of the total bulk. This allows to each person 4 cubic feet per minute, which is not sufficient for healthful respiration.

From the column under "Cubic Feet of Air per Minute for One Person," which was calculated in the above manner, it will be seen that six of the rooms visited gave only 5 cubic feet or less of pure air per minute to each

person, a quantity insufficient for healthful occupancy according to all authorities. Eleven other rooms gave only 10 cubic feet or less per minute, an amount insufficient to remove the disagreeable odours of animal effluvia. In a few instances the temperature and percentage of moisture found below the generally recognised standard, but these may have been accidental.

The general management of these schools is worthy of praise. The systematic arrangement of studies, thoroughness of instruction, and excellence of discipline, are such as to enlist the sympathy of all classes and command the patronage of those who have children to educate; but the adoption of a more efficient system of ventilation is demanded in view of the facts presented and the important interests involved.

The Discussion on Mr. Hollway's New Process in Metallurgy.—We have been requested to announce that a renewal of the discussion on Mr. Hollway's paper, "A New Application of Rapid Oxidation by which Sulphides are Utilised as Fuel," will take place at the Society of Arts on Wednesday evening next, April 30, at 8 o'clock. Dr. Roscoe, F.R.S., will preside.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, April 17, 1879.

Dr. Roscoe, Vice-President, in the Chair.

AFTER the minutes of the previous meeting had been read and confirmed, the following certificates were read for the first time:—A. E. Robinson, R. Reid, and H. Appleby. During the evening the following were declared to be duly elected Fellows of the Society:—W. E. Blythe, W. A. Bradbury, A. H. Black, T. Griffiths, W. T. Gent, C. H. Hutchinson, F. A. B. Jewson, W. Johnstone, W. T. Lawson, J. L. Macmillan, W. North, J. A. Ogilvie, F. Podmore, W. Palmer, T. Palmer, G. Rait, W. Radford, W. Stone, A. W. Stokes, W. Spottiswoode, P.R.S., C. Slater, W. B. Turner, F. L. Teed, V. H. Velez, Thorp Whitaker, T. H. Walker.

The SECRETARY then read a paper "*On Heptane from Pinus Sabiana*," by T. E. THORPE. In the *Pharmaceutical Journal*, March 30, 1872, W. Wenzell, described, under the name of Abietene, a new hydrocarbon obtained by distilling the exudation of the *Pinus sabiana*, a tree indigenous to California, known locally as the nut pine, or digger's pine. To procure the exudation, the tree during winter is notched and guttered at a convenient height from the ground. The resin on distillation yields the liquid hydrocarbon. The crude oil is met with in San Francisco as an article of commerce under the names of abietene, erasine, &c., as a substitute for benzolin, for removing grease spots, &c. It is a nearly colourless mobile liquid, of a powerful aromatic smell, resembling that of oil of oranges. Wenzell contrasts its characters with those of terebene from *P. Sylvestris*. Abietene, sp. gr. 0.694, boils at 101°, dissolves but a small quantity of hydrochloric acid gas, and is but little attacked by cold nitric acid. Terebene, sp. gr. 0.840, boils at 160°, absorbs HCl with avidity, and is violently attacked by nitric acid. From a consideration of the general properties and behaviour of this hydrocarbon the author of the present paper concluded that it was likely to be a paraffin. The occurrence of a paraffin playing the part of oil of turpentine in the vegetable kingdom was hitherto unheard of, the only natural sources of this hydrocarbon (heptane) being petroleum and fossil fish-oil. The author, therefore, obtained from Mr. Wenzell 2 gallons of the abietene, and has subjected it to a most exhaustive chemical and physical examination, the details of which are contained in the paper. The crude oil is slightly contaminated with a resinoid matter, to which its smell is due. The pure oil boils at 98.42° C. at 760 m.m. It has the composition of heptane, containing 83.85 per cent C, 16.03 per cent H (C₇H₁₆ requires C 83.97, and H 16.03). Vapour density—found, 49.94; calculated, 50.07; sp. gr. at 0° 0.70057. The rate of expansion by heat has been carefully determined: its volume at the boiling-point is 1.1411. Its specific volume 162.54; refractive index for D, 1.3879; its molecular refractive energy, 56.4. Rotates in a tube 200 m.m. +6.9°. Its viscosity and surface tension were also determined. The author has compared the heptane obtained from *P. Sabiana* with the heptane from petroleum and that obtained by heating azelaic acid with baryta. The sp. gr. of the heptane from petroleum is 0.7301; that from azelaic acid has a sp. gr. of 0.700. These heptanes are believed by Schorlemmer to be identical. The author is at present engaged in an investigation of this point.

The CHAIRMAN said the Society was much indebted to Dr. Thorpe for this elaborate investigation, and for the extremely careful and able manner in which he had worked out the subject.

Dr. ARMSTRONG said that he had detected in ordinary turpentines a paraffin-like substance in small quantities,

½ to 2 per cent. It was very remarkable that a paraffin should be found in such a state of purity in a plant.

Mr. ATTWOOD said that the composition of the oil would probably vary at different seasons. Sometimes the nuts of this pine tasted very strongly of turpentine, whilst at others the taste was almost imperceptible.

The next communication was "*On the Determination of Tartaric Acid in Lees and Inferior Argol, with some remarks on Filtration and Precipitation*," by B. J. GROSJEAN. "Lees" is the name given to the deposit in fermenting wine vats, "argol" being the crystalline crust which forms on the sides. The first direct method for determining the tartaric acid in "lees," &c., was suggested by Warington (*Chem. Soc. Journ.*, [2], xiii., 973); it is known as the "oxalate method." It consists in treating the finely-ground lees with a little water, and heating the mixture to 100°; an excess of neutral potassium oxalate is then added, and the whole digested for a quarter of an hour, the free acidity is nearly neutralised with caustic potash, the whole is filtered on a vacuum filter, and the residue washed; the filtrate and washings are concentrated, and an excess of citric acid added; the tartaric acid is thereby precipitated as potassium bitartrate. This salt is collected, washed, and the tartaric acid determined by titration with standard alkali. The author considers this process in detail, giving fullest details, and illustrating many obscure points with quantitative experiments:—1. *Treatment with Potassium Oxalate*.—The amount of lime present must be roughly determined (a method for this purpose is given), and 1½ grms. of the oxalate are added to ensure the decomposition of the calcium tartrate. The sample taken for analysis should contain about 2 grms. of tartaric acid. 2. *Neutralisation with Caustic Potash*.—Care must be taken to add the alkali drop by drop with constant stirring, so that the alkali is never in excess. 3. *Filtration from the Residue*. The author uses the vacuum filter suggested by Casamajor (*CHEMICAL NEWS*, vol. xxxii., p. 45). It consists of a perforated disc of platinum, lead, or pumice, placed in a funnel of peculiar shape. The disc is covered by a slightly larger circle of paper. The pressure keeps the paper so closely applied to the sides of the funnel that no precipitate passes, but at the same time a speedy and a thorough washing is ensured. The author finds that this plan has many advantages over that proposed by Bunsen, but states that an ordinary funnel can be used instead of the special funnel proposed by Casamajor. In some cases the paper disc should be covered with a layer of roughly ground pumice, freed from air, before commencing the filtration. The author recommends that the wash-water be allowed to run through until the residue presents on the surface no visible moisture, without waiting for it to crack, and then immediately to pour on a fresh portion of wash-water. The vacuum most advantageous is 250 m.m. mercury. By following this plan the potassium tartrate will be completely washed out of the sample of lees in ten washings of 2 to 3 c.c. each. This is proved by quantitative experiments. Various plans have to be adopted if the filtration refuse to proceed quickly. 4. *Addition of Potassium Chloride*.—The author recommends the addition of 5 grms. of KCl to render the precipitation of the bitartrate more complete. Thus, water at 12° dissolves 1 part of bitartrate in 262, whereas a 10 per cent solution of KCl dissolves only 1 part in 4401. 5. *Quantity of Citric Acid Required*.—An excess of 1 to 1.5 gm. of citric acid should be added. If 2 grms. of tartaric acid are present, 2 to 2.5 grms. citric acid are required to effect complete precipitation. 6. *The Mode of Precipitating the Bitartrate*.—A 50 per cent solution of citric acid is most convenient. The author prefers to precipitate the bitartrate in the state of minute granular crystals. This is effected by constantly stirring the liquid after adding the citric acid in the cold. 7. *Complete Precipitation of the Bitartrate is effected by thus stirring continuously for ten minutes*.—The author recommends that the mixture be allowed to stand for twenty minutes after the ten minutes stirring. 8. *Filtration and Washing of*

the Bitartrate.—The washing is effected by a 5 per cent solution of potassium chloride saturated with potassium bitartrate at the temperature of the air at the time of washing. 9. *The Accuracy of the Process.*—The author obtained 99.6, 99.86 instead of 100 parts of tartaric acid taken. 10. *Time Required for the Complete Estimation.*—This the author gives as four hours. In the course of his communication the author exhibited the method of filtering, the insolubility of bitartrate in a solution of potassium chloride, &c.

The next paper was entitled "*Conditions Affecting the Equilibrium of certain Chemical Systems*," by M. M. P. MUIR. The author has quantitatively studied the two reactions, which may be formulated as follows:—

In action A it is shown that the greater the value of x'' (x and n being constant) the more rapidly will equilibrium be attained; if x'' be small n will vary at different moments and will always be somewhat large. If $n=0$ the value of x varies from 450 to 460 molecules (x and x' being each equal to 1). If n is approximately equal to x , i.e., if permanent formation of BiOCl just commences, then if x' be doubled, x'' must be more than doubled, or x'' must increase in a more rapid ratio than x' . If initial equilibrium be disturbed, but without the production of a new stable state of equilibrium, the production of this disturbance is dependent not only on the relative but also on the absolute number of BiCl₃ and H₂O molecules present. The production of a new stable equilibrium is dependent only upon the relative number of molecules. In the rush of the interacting molecules the water molecules get entangled among the hydrochloric acid molecules, the greater the number of the latter (even when the proportion of HCl to H₂O is maintained constant) the greater is the entanglement. If the system has, however, time to act and react, then the result is independent of the absolute number of the molecules provided the proportion of the HCl to H₂O molecules be constant. If water be run very cautiously into a solution of BiCl₃ in HCl until a small amount of BiOCl is formed at the junction of the two liquids and the whole be then shaken up, a greater amount of BiOCl is produced in short times than if the water is added with constant stirring. During long periods of time the result is the same in both cases. In action B a condition of stable equilibrium is attained (x and x' being each equal to 1) before the whole of the CaCl₂ is decomposed; small causes tend to disturb this equilibrium. In reaction A a small amount of chemical change seems to be accompanied with but small changes in the Entropy of the system; hence the chemically reacting system soon attains a condition of equilibrium. But in reaction B a small amount of chemical change is probably accompanied with considerable changes of Entropy, so that, if time be given, the reaction will be nearly completed. In B the influence of temperature is marked when equal molecules of the reacting bodies are used; if 2 or more molecules of alkaline carbonate be used to 1 molecule of CaCl₂, the change in a given time depends but little on temperature. With equal molecules at ordinary temperature a state of permanently stable equilibrium is attained in about sixty minutes; if the temperature be raised this point of equilibrium is passed and the change is very nearly or even quite completed. Time causes an increase in the amount of chemical change, its influence being specially marked at low temperatures, i.e., when the molecular mobility of the system is small. With equal molecules of CaCl and M₂CO₃ the change formulated is complete if somewhat high temperatures and long times be employed. If the mass of one of the reacting bodies

be increased, the change is completed in a short time and at low temperatures.

Mr. M. M. P. MUIR then read a paper on "*The Action of Aqueous Hydrochloric Acid upon Bismuthous Oxide.*" When bismuthous oxide is added to aqueous hydrochloric acid the oxide is dissolved, but a point is soon reached after which the bismuth in solution is precipitated as bismuthyl chloride (BiOCl), while the oxide added is simultaneously transformed into the same salt. Finally the whole of the bismuth is present in the form of insoluble bismuthyl chloride. The action of aqueous hydrochloric acid upon bismuthous oxide, so far as the initial and final distributions of mass are concerned, may be thus formulated—

The presence of water renders possible an action between HCl and Bi₂O₃, which action would not occur in its absence.

The three following papers were, in consequence of the lateness of the hour, taken as read:—

"*On the Action of Oxides on Salts, Part II.*," by E. J. MILLS and J. W. PRATT. This paper continues the work contained in Part I., recently communicated to the Society. The authors have examined the actions of aluminic, ferric, and stannic oxides on potassic carbonate. The weight of the carbonate was the same as in Part I., and was kept constant; the temperature was about 735°, and the time three hours. The results obtained are given in a series of tables.

"*Examination of Substances by the Time Method*," by J. B. HANNAY. In a former paper the author gave an account of his method by which the thermal dissociation of a hydrated salt may easily be followed. The results of an examination of double salts, the deportment of whose components in the free state was known, are contained in the present paper. The double salts examined were the sulphate of magnesium and zinc, 14H₂O; the double sulphate of iron and magnesium; the double sulphate of copper and magnesium. Great care was taken to ensure the purity of the salts. The conclusion at which the author has arrived is as follows:—Two hydrated salts in forming a double salt containing the normal amount of water expend one half of the affinity of the anhydrous salt for its water of crystallisation in combining with each other, showing that the formation of double salts is comparable with other forms of chemical action.

"*Preliminary Note on Certain Compounds of Naphthalen and Benzene with Antimony Trichloride, &c.*," by WATSON SMITH. While distilling a mixture of antimony trichloride and naphthalen through a red-hot tube with the object of preparing dinaphthyl, this mixture was found to contain a little water accidentally admitted. On clearing out the tube long white needles were obtained; they contained antimony and carbon, but no chlorine. Heated on platinum foil the crystals melted at a red heat, burnt, and disappeared. The author believes this body to be trinaphthyl stibine or naphthyl-oxy-stibine. On melting together a mixture of naphthalen and antimony trichloride and allowing to cool, clino-rhombic crystals were obtained, crystallising unaltered from petroleum ether. The author has obtained other crystalline compounds, and thinks it probable that by the action of the antimony potassium alloy on bromo-naphthalen or bromobenzene at high temperatures trinaphthyl-stibine and triphenyl-stibine would be obtained.

The Society then adjourned to May 1, when the following papers will be read:—"On the Volumes of Liquids at their Boiling-points Obtainable from Unit Volumes of Gases," by W. Ramsay; "On a Method of Precipitating Manganese entirely as Dioxide, and its Application to the Volumetric Determination of Manganese," by J. Pattinson; "On the Determination of Nitric Acid as Nitric Oxide by Means of its Action on Mercury," by R. Warington,

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 12, March 24, 1879.

The Slow Changes Experienced by Wines during its Preservation.—M. Berthelot.—The author has made a comparative examination of two samples of port, the one made in the year 1780, and the other forty-five years old, determining the proportion of dissolved gases, of alcohol, sugars, acids, and tartar.

Remarks on Certain Points of Crystallogenesis.—Lecoq de Boisbaudran.—Since the resistance to a change of condition is not alike for the different planes of the same crystal, its solubility must vary with its outward form. Thus a supersaturated solution of basic alum being treated at a given temperature with cubes of this salt (or with portions cut according to the cubic surfaces) will not possess the same specific gravity as in cases where the desupersaturation has been effected by contact with octahedra (or portions cut according to the octahedral surfaces). The former liquid will be more concentrated than the latter, and after it has ceased giving up matter to the cubes it will still be capable of depositing upon octahedra. Even if we consider a single system of surfaces only the principle of resistance to a change of condition leads us to recognise two unequal specific gravities for a saturated liquid at a given temperature, according as we begin with a dilute or a supersaturated solution. The solubility of any substance is therefore not sufficiently defined by the quantity contained in the liquid at a given temperature in presence of an excess of the solid substance. We must further specify the species of surfaces and the direction in which the operation has been conducted. If the desupersaturation of a solution is obtained by means of crystals having several orders of surfaces there are two possible cases:—(1.) The quantity of liquid is great in proportion to the immersed masses; the crystals then assume their most stable form, and the final specific gravity is what corresponds to this system of surfaces. (2.) The quantity of liquid is very limited; the crystals cannot in these conditions assimilate matter enough to complete their form of maximum stability, and several orders of surfaces subsist indefinitely: the final specific gravity is that which corresponds to the system of surfaces destined to disappear first if the crystals could continue to grow.

Molecular Vibrations in the Magnetic Metals during the Passage of Undulatory Currents.—M. Ader.—In all the magnetic metals the passage of an undulatory current determines in their interior molecular vibrations, which, if collected, give articulate sounds. In order that the vibrations may appear with their full intensity on the exterior of the metals it is necessary to oppose to the wires or bars a mechanical action, especially the inertia of two heavy masses at their extremities.

Ytterbia, the New Earth of M. Marignac.—L. F. Nilson.—The author has succeeded in preparing perfectly pure ytterbia, presenting no trace of an absorption ray, and having a molecular weight between 131.92 and 132.17. The erbia of all preceding authors, including M. Marignac, consists chiefly of ytterbia, to which very small quantities of erbia give a rose colouration. Ytterbia is probably Yb_2O_3 .

Scandium, a New Element.—L. F. Nilson.—The author has extracted from impure erbia a substance whose spectroscopic behaviour indicates its novelty. Its atomic weight calculated for the formula of the earth ScO is below 90.

Potassium Cyanosulphite.—A. Etard.—This compound is obtained by substituting CN for OH in hydrated sulphurous acid. It dissolves in water, cold or hot, without decomposition, evolves ammonia if boiled with a caustic alkali, and reduces salts of gold and silver.

Thermo-chemical Study on the Alkalino-earthly Sulphides.—P. Sabatier.—Not susceptible of abstraction.

Certain Alcoholic Iodides and Bromides.—J. de Montgolfier and E. Girard.—An examination of the bromides of ethyl and isopropyl, and of the chloro-bromide of ethylene.

Formation of Aurin.—Ph. de Clermont and J. Frommel.—The authors contend that carbonic acid does not intervene as such in the formation of aurin, the action being due to carbon and oxygen in a nascent state.

Presence of Lithia in Rocks and in Sea-waters.—L. Dieulafoy.—Lithia is as widely distributed as soda and potassa, and accompanies these two bases in all primordial rocks. In sea-water it may be detected in the residue from the evaporation of a single c.c.

Archives Néerlandaises des Sciences.

Tome xiii., 5me Livraison.

Decomposition of Calcium Chloride by Water.—H. C. Dibbits.—Crystalline calcium chloride ($\text{CaCl}_2 + 6\text{H}_2\text{O}$) loses in dry air, even below 10° , five molecules of water, the first four of which escape readily and the last much more slowly. At 80° the salt becomes completely anhydrous in dry air. When the salt loses all its crystalline water at a temperature not exceeding 130° no appreciable loss of hydrochloric acid takes place. Between 130° and 140° the escape of acid becomes perceptible. The more the temperature rises the more hydrochloric acid escapes, still even if gently heated over a naked flame the decomposition is so slight that not more than 0.03 per cent of the acid is lost. Even at 150° the loss is so slight that it remains entirely within the ordinary limit of error.

Les Mondes, Revue Hebdomadaire des Sciences.

No. 12, March 20, 1879.

Works of the Liebig Extract of Meat Company at Fray Bentos.—At this establishment from 10,000 to 12,000 oxen are slaughtered yearly. In 1877, 15 million kilos. of leather, tallow, and manure were exported to Europe, whilst 1½ million kilos. of *tasajo*, or dried beef, were sent to Brazil and Cuba.

Lecture on the Phylloxera.—M. Bouchardat.—The author does not think that any remedy universally applicable can be found, nor does he entertain the hope that the Phylloxera will ultimately disappear. He likens the case to that of the *Oidium Tuckeri*, a previous vine pest, and to the *Botrytis infestans*, the cause of the potato blight.

Cases of Phosphorescence Observed.—M. Nueesch.—In a certain butcher's shop all the meat became strongly phosphorescent and remained so as long as sound. If putrefaction set in and *Bacterium termo* made its appearance the luminous appearance ceased. None of the customers of the meat experienced any inconvenience from its use, and no similar phenomenon was traced in other butchers' shops in the neighbourhood.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin,
No. 17, 1879.

Monohydrated Sulphate of Soda and Dihydrated Carbonate of Soda.—Julius Thomsen.—The salt deposited on heating a solution of ordinary 10-hydrated sulphate of soda, saturated at 30° was generally supposed to be anhydrous. The author finds that it retains 1 mol. of water. The salt deposited on heating 10-hydrated carbonate of soda contains not 1 mol. water but 2,

Composition of Copper Sulphide Formed in the Moist Way.—Julius Thomsen.—The precipitate formed in solutions of copper oxide by means of hydrogen or sodium sulphide is not CuS but a mixture of sulphur with a lower copper sulphide. The affinity of copper for sulphur is satisfied with the formation of Cu_2S , which is accompanied by a liberation of heat to the extent of 20,240 cal., and the reception of a further quantity of sulphur takes place without noticeable rise of temperature.

Zinc Sulph-hydrate.—Julius Thomsen.—If a zinc sulphate solution is mixed with a double equivalent of a solution of sodium sulph-hydrate no precipitate is obtained but a clear or slightly opalescent solution.

Density and Décomposition of the Vapour of Hyponitric Acid at Various Pressures below its Boiling-Point.—Alex. Naumann.—This paper consists essentially of tables of the density of hyponitric vapour at various temperatures and pressures, showing the amount of decomposition produced. It appears that at equal temperatures and with decreasing pressure the decomposition increases as also at equal pressure with increasing temperature.

Electrolytic Determination of Cadmium.—E. J. Smith.—The author has tried the aqueous solution of cadmic acetate with perfectly satisfactory results. The time required for the deposition of the metal is three to four hours. A tolerably strong current should be employed and the solution should contain 2 per cent of the metal.

Constitution of the Propyl Group in Cymol.—O. Jacobsen.

Constitution of Oxy-mesitylenic Acid.—O. Jacobsen.—These two papers are not adapted for useful abstraction.

Behaviour of Certain Nitro-Compounds with Sulphuretted Hydrogen.—F. Beilstein and A. Kurbatow.—The authors have examined chlor-dinitro-benzol, nitro-para-dichlor-benzol, chlor-ortho-dinitro-benzol, and symmetrical nitro-meta-dichlor-benzol. They state that sulphuretted hydrogen exerts a reducing action upon chlor-nitro-derivatives only when the nitro-group is not situated along with chlorine or another nitro-group.

Convenient Method for the Preparation of Mono-chlor-hydrin-sulphuric Acid.—H. Beckurts and R. Otto.

Method of Action of Mono-chlor-hydrin-sulphuric Acid.—H. Beckurts and R. Otto.

Synthesis of Aromatic Sulphones from the Chlor-anhydrides of the Sulphonic Acids and Hydro-carbons by Means of Aluminic Chloride.—These three papers do not admit of useful abstraction.

Further Contributions to the Knowledge of the Formation and Constitution of the Disulphoxides of Benzol and Toluol.—C. Pauly and R. Otto.—The authors have formerly shown that benzol-disulphoxide and benzol-zinc-mercaptid act upon each other readily and completely with the formation of benzol-disulphide and benzol-sulphinat of zinc. An analogous decomposition takes place with the corresponding toluol compounds.

Decomposition of Ethyl-disulphoxide by Potassium Hydroxide.—C. Pauly and R. Otto.—Ethyl-disulphoxide may be regarded as a thio-ether.

Action of Mono-chlor-hydrin-sulphuric Acid upon Sulpho-benzid.—R. Otto and A. Knoll.—In this preliminary communication the authors announce the formation of sulpho-benzid-sulphonic acid, with the examination of which they are engaged.

Diethyl-glyoxylic Ether and Diethyl-glyoxylic Amide.—A. Geuther.—With reference to a paper by Finnet the author points out that the two compounds above mentioned were prepared by Schreiber from dichlor-acetic acid eight years ago.

MISCELLANEOUS.

Lectures on Hygiene and Public Health.—The first lecture of Professor Corfield's course on Hygiene and Public Health will be delivered at University College on Thursday, May 1, at 4 p.m. The course will be illustrated by models and specimens from the Parkes Museum of Hygiene. Practical instruction in the methods of analysis of air, water, foods, and drugs will be given in the Hygiene Laboratory by Professor Corfield and Mr. C. E. Cassal, F.C.S., the Demonstrator.

Society of Arts.—The third course of "Cantor Lectures" for the present session of the Society of Arts is by Mr. W. H. Preece, the Electrical Engineer of the Post-Office, on "Recent Advances on Telegraphy." The course commenced on April 21. The first lecture dealt with definitions, electrical effects, and sources; economical distribution of electric currents. The second will treat principally of the transference of electricity, and will include also such subjects as wires, insulators, supports, gutta-percha, india-rubber, underground wires and cables; The third will be devoted to simple telegraphy, visual and aural signals, telephones, and telegraphic writing. The fourth will deal with duplex, quadruplex, multiplex, and harmonic telegraphy. The fifth and last is to be devoted to automatic and fast-speed telegraphy.

NOTES AND QUERIES.

Composition of Honey.—In reply to E. H. S.'s query he will find some recent investigations as to the chemical composition of honey by Dr. Campbell Brown in *The Analyst*, vol. iii., p. 267, 1878.—G. W. W.

Solvent for Gelatine.—What is the most perfect (volatile) solvent for gelatine? What work is there where the subject is fully entered into?—M. NEWMAN.

MEETINGS FOR THE WEEK.

- MONDAY, 28th.**—Medical, 8.30.
— Society of Arts, 8. "Recent Advances in Telegraphy," by W. H. Preece. (Cantor Lectures.)
— Royal Geographical, 8.30.
TUESDAY, 29th.—Civil Engineers, 8.
— Royal Institution, 3. "Mendelssohn," by Mr. Ernst Pauer.
— Anthropological, 8.
— Zoological, 1. (Anniversary).
— Society of Arts, 8. "Light Railways for Opening up a Trade with Central Africa," by John B. Fell.
— "The Advantage of Railway Communication in Africa, as Compared with any other Mode of Transport," by J. Conyers Morrell. (African Section.)
WEDNESDAY, 30th.—Society of Arts, 8. Renewed Discussion on Mr. John Hollway's Paper on "A New Process in Metallurgy."
— Geological, 6.
THURSDAY, May 1st.—Royal, 8.30.
— Royal Institution, 2. Annual Meeting.
— Chemical, 8. "On the Volumes of Liquids at their Boiling-Points Obtainable from Unit Volumes of Gases," by Dr. W. Ramsay.
— "On a Method of Precipitating Manganese Entirely as Dioxide, and its Application to the Volumetric Determination of Manganese," by J. Pattinson. "On the Determination of Nitric Acid as Nitric Oxide by Means of its Action on Mercury," by R. Warington.
— Royal Society Club, 6.30.
FRIDAY, 2nd.—Royal Institution, 9. "Action of Anæsthetics," by Prof. McKendrick.
— Geologists' Association, 8.
— Society of Arts, 8. "The Wild Silks of India, especially Tusseh," by Thomas Wardle. (Indian Section.)
SATURDAY, 3rd.—Royal Institution, 3. "Architecture," by Mr. H. H. Statham.

ERRATUM.—No. 1012, p. 170, line 12 from top, read p. 148 for p. 198.

In one volume 8vo., pp. 1048, £1 11s. 6d.,
EXPERIMENTAL RESEARCHES IN

THE

PATENTEES' MANUAL.

A Treatise on the Law and Practice of Letters Patent,
 especially intended for the use of Patentees and Inventors.

BY

JAMES JOHNSON, ESQ.,

Of the Middle Temple, Barrister-at-Law, and

J. HENRY JOHNSON,

Solicitor and Patent Agent, Assoc. Inst. C.E. 47, Lincoln's
 Inn Fields, W.C., and Glasgow.

This Edition, much enlarged, gives a practical reference
 to every reported case of importance, and contains all the
 information on the law and practice of Patents Inventors
 and Patentees can require.

The Appendix contains the Statutes and Rules, and a
 summary of the Laws of all Foreign States and British
 Colonies.

London: LONGMANS and CO.

Prestolee Alkali Works, Farnworth, near Manchester and Bolton.

MESSRS. FULLER, HORSEY, SONS,
 and CO. will include in their SALE by AUCTION, under
 a distraint for rent, on the PREMISES, Farnworth, near Manches-
 ter, on THURSDAY, May 1st, at 11 precisely, THE REMAINING
 STOCK IN TRADE, including about 1000 tons of acid in chambers,
 stock of bleaching liquors, &c., in process of manufacture; 100 tons
 Limestone, &c.—May be viewed the day preceding and morning
 of sale, and catalogues had on the premises, at the principal Hotels
 at Manchester and Bolton, of Messrs. Wakeman and Bleack, Solici-
 tors, Warminster; of Messrs. Fuller, Horsey, Sons, and Co.,
 11, Billiter Square, London, E.C.

GEOLOGY.—In the Preface to the Student's
 ELEMENTS OF GEOLOGY, by Sir Charles Lyell, price 9s.,
 he says:—"As it is impossible to enable the reader to recognise rocks
 and minerals at sight by aid of verbal descriptions or figures, he will
 do well to obtain a well-arranged collection of specimens, such as may
 be procured from Mr. TENNANT (149, Strand), Teacher of Mineralogy
 at King's College, London." These Collections are supplied on the
 following terms, in plain Mahogany Cabinets:—

100 Specimens, in Cabinet, with 3 Trays..	..	£2 2 0
200 Specimens, in Cabinet, with 5 Trays..	..	3 5 0
300 Specimens, in Cabinet, with 9 Drawers ..	..	10 10 0
400 Specimens, in Cabinet, with 13 Drawers ..	..	21 0 0

More extensive collections at 30 to 5000 Guineas each.

MINERALS FOR CHEMISTS, &c.

NEW AND REVISED LIST, with Prices of Minerals containing
 rare Elements, &c., for Chemical Purposes, Experiment, and Research.
 Also, Elementary Collections of Minerals, Fossils, and Rocks, for
 Students, Schools, Colleges, &c.

NEW PATTERNS OF GEOLOGICAL HAMMERS.
 NEW CATALOGUE OF SECONDHAND AND NEW BOOKS,
 NOW READY.

JAMES R. GREGORY,
 MINERALOGIST,

88, CHARLOTTE STREET, FITZROY SQUARE.

MANGANESE

SPECIALITIES.

Lump, Crystallised, Ground, and Prepared
 Large stock of every description.
 "Suitable for all Trades."

ARSENIO

FLUOR-SPAR

Refined powdered, Lump Grey, and Ruby.

Finest produced. Medium and Common for all
 purposes.

BARYTES

Carbonate and Sulphate. All qualities of Lump
 and Ground.

BAUXITE

Of high percentage of Alumina and low in Iron

CRYOLITE, MAGNESITE, CHROME ORES, EMERY
 STONE, AND ALL MINERAL ORES &c.

GEO. G. BLACKWELL,

MINERAL AND CHEMICAL BROKER,

5, CHAPEL STREET, LIVERPOOL

NOTE.—SPECIAL ATTENTION is directed to my CARBON-
 ATE AND SULPHATE OF BARYTES as the *finest*
 produced, being clean, crystallised, free from Lime,
 and of the *highest test*.

CHEMICAL NEWS.

Vol. XXXIX. No. 1014.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

By Professor ABEL, C.B. F.R.S.

(Continued from p. 179.)

THE physical character of explosive substances, as also the mechanical condition of a mass of the particular explosive substance operated on, are of great influence in determining its behaviour when submitted to the action of an initiative detonation. The liquid nitro-glycerin is far more sensitive to detonation than gun-cotton; one grain of mercuric fulminate, confined in a metal case, suffices to detonate nitro-glycerin when surrounded by it; but, in order to attain this result with any degree of certainty, it is necessary so to confine the nitro-glycerin as to prevent its yielding to the blow developed by the initiative detonation, and thus to some extent escaping from the operation of the sudden concussion to which the particles contiguous to the fulminate charge are submitted.

If nitro-glycerin be mixed with solid substances in a fine state of division plastic mixtures may be obtained, and the liquid may thus be presented in something like a solid form to the detonating agent. If the particles of absorbent material be, moreover, of porous nature, as is the case with the infusorial earth called Kieselguhr, used in the production of dynamite, a solid nitro-glycerin preparation may be obtained which contains a very large proportion of the liquid (75 per cent by weight). In this condition nitro-glycerin may be detonated without any difficulty when freely exposed to air; and although it is diluted with a considerable proportion of absolutely inert material, its sensitiveness to detonation is not in the least diminished. Each particle of the diluent is enveloped in the liquid, so that no portion of the latter becomes isolated from the remainder by the admixture of inert solid matter; hence, when the initiative detonator is surrounded by such a mass it is in contact at all points with some portion of the nitro-glycerin, and the latter is in continuous connection throughout, though no longer in a mobile condition; detonation is consequently as readily established and transmitted through the mass as though it consisted entirely of nitro-glycerin. Indeed, while the liquid in its undiluted state, if freely exposed to air in a long layer, transmits detonation with difficulty and very slowly as compared with compressed gun-cotton (the observed rate of progression being, in several experiments, below 6000 feet per second), detonation is transmitted with ease and certainty through very long trains of a solid preparation of nitro-glycerin, such as dynamite, and the rate of transmission is decidedly more rapid than it is with compressed gun-cotton, a result which is in harmony with the greater sensitiveness to detonation and the greater violence of action of nitro-glycerin.

It has already been stated that gun-cotton may be detonated if a confined charge of not less than 2 grains of mercuric fulminate be detonated when closely surrounded by the substance. But in order to attain this result, the cellulose product must be presented to the detonating agent in a mechanical condition favourable to its action.

Gun-cotton in a loose flocculent condition, or even if in the more compact form of a spun yarn or thread, cannot be detonated through the agency of a large fulminate buried in the material. The light and loose gun-cotton is simply scattered with violence; portions are sometimes

inflamed by the heat developed where the fulminate is detonated, a result which is obtained with greater certainty the less violent the detonation produced by the fulminate charge. If, however, the gun-cotton be converted into a compact form, either by ramming the wool or thread very tightly into a case, or better still, by reducing the gun-cotton fibre to a very fine state of division, and compressing it, when in that condition, into compact masses, it becomes susceptible of detonation by the initiative action of mercuric fulminate, and the quantity of the latter required to bring about detonation is small (down to the limit which has been named above) in proportion as the compactness or density of the compressed material is increased.

Detonation, when established in compressed gun-cotton, is transmitted with great velocity throughout the mass, as already stated, or from one to another of contiguous masses, laid out in long rows, and even, though at a reduced rate, if small spaces exist between the individual masses. But, if a small mass of compressed gun-cotton freely exposed to air be detonated when in immediate contact with gun-cotton wool or loosely twisted yarn, the detonation will not be transmitted to these, but they will merely be scattered and perhaps inflamed.

The difference in the behaviour of nitro-glycerin and of gun-cotton when presented to the action of a so-called initiative detonation under the different conditions spoken of above, admits of ready explanation.

It was established, in the first instance, that the action of an initiative detonation is not ascribable to the heat developed within the detonating material itself in undergoing chemical metamorphosis. If it were so, the detonating mixture known as percussion-cap composition and other explosive mixtures, the detonation of which is attended by much greater development of heat than is obtained by the action of pure mercuric fulminate, should detonate gun-cotton more readily than the latter does, whereas very much larger quantities of such materials are required to attain that result. Moreover, the readiness with which gun-cotton is detonated should be solely proportionate to the amount of fulminate used, which has been shown not to be the case; and gun-cotton should be more readily detonated when in the loose and open condition than in the highly compressed or compact form, because the latter presents it in the condition least favourable, and the former in that most favourable, to ready and rapid transformation by heat. Again, the actual temperature required for the explosion of nitro-glycerin is very considerably above the exploding temperature of gun-cotton, yet a very much smaller charge is required for the detonation of nitro-glycerin than is needed for the detonation of gun-cotton. On the other hand, a quantity of confined percussion-cap composition which, if it were pure mercuric fulminate, would be altogether inadequate for the detonation of gun-cotton, suffices for the detonation of nitro-glycerin.

The action of an initiative detonation has already been compared to that of a blow from a hammer or falling weight. The readiness and certainty with which gunpowder, gun-cotton, and other explosive agents are detonated by the latter agency are regulated by several circumstances; they are in direct proportion to the weight of the falling body, to the height of its fall, and to the force with which it is impelled downwards; to the velocity of its motion; to the mass and rigidity or hardness of the support upon which the substance to be detonated rests; lastly, to the quantity and mechanical condition of the explosive agent struck, and to its sensitiveness.

Gunpowder is much more readily detonated by a sharp blow from a small hammer than by the simple fall of a heavy hammer, or by a comparatively weak blow from the latter. It is very difficult by repeated blows, applied at very brief intervals, to detonate gun-cotton if placed upon a support of wood or lead, both of which materials yield to a blow, the force applied by that blow being transferred through the explosive agent and absorbed in work done upon the material composing the support. But if the latter

* Abstract of a Paper read before the Royal Institution of Great Britain, Friday, March 21, 1879.

be of iron, which does not yield permanently to the blow of the hammer, the detonation of those substances is easily accomplished. If the quantity of the explosive agent employed be so considerable as to form a thick layer between the hammer and support, the force applied is to so great an extent expended in imparting motion to the particles of the compressible mass, that there remains little or none by which its detonation can be accomplished, and if the material be in a loose or porous condition (as in the case of a powder or a loose wool), much work has to be accomplished in moving particles of the mass through a comparatively considerable space, in the operation of compressing them, so that a second or even a third blow is required for their detonation; whereas if, by blows or pressure previously applied, the explosive material will be presented in the form of a compact mass, the particles of which have little tendency to motion when force is applied to them, detonation will be much more readily developed. It appears, therefore, that the detonation of an explosive substance by means of a blow is the result of the development of heat sufficient to bring about most energetic chemical action, or change, by expenditure of force in the compression of the material, or by establishing violent friction between its particles, consequent upon the motion momentarily imparted to them, and that it is brought about with readiness proportionate to the resistance which they oppose to their motion by the degree of their contiguity to each other.

The exceedingly violent motion of particles resulting from the sudden or extremely rapid transformation of a solid or liquid explosive body into highly heated gas or vapour (which is the effect of a detonation), must obviously exert force which operates upon a body opposed to it in a manner precisely similar to the force applied by opposing a body in the path of a solid mass which is set into very rapid motion. In other words, a detonation exerts a mechanical effect upon resisting bodies precisely similar to that of a blow from a hammer or from a projectile propelled from a gun. Just as the force of a sufficiently sudden or powerful blow from a hammer is transformed into heat by the resistance to the motion of the hammer which the particles of an opposing body offer, and by the consequent friction established between them, so the force or concussive action exerted by the matter set in motion when a solid or liquid is converted into gas or vapour, will also be transformed into heat, the development of which in an opposing body will be proportionate to the resistance to motion which its particles offer, and to the suddenness and violence of the concussion to which it is subjected. The power of accomplishing the detonation of nitro-glycerine, gun-cotton, or other highly explosive substances, freely exposed to the air, through the agency of detonation produced in their vicinity or in close contact with them, appears therefore correctly ascribable to the heat suddenly developed in some portion of the mass by the mechanical effect, or blow exerted by that detonation, and is regulated by the violence and suddenness (either singly or combined) of the detonation, by the extent to which the particles composing the mass of the explosive material are in a condition to oppose resistance to the force, and by the degree of sensitiveness of the substance to detonation, or to sudden metamorphosis, under the influence of heat thus developed.

(To be continued.)

Eupitton and Pittakall.—A. Grätzell.—The author points out a number of characteristics which distinguish eupitton from pittakall. The latter gives a blue precipitate with alkalis even in an acid solution, whilst eupitton forms a brown precipitate. Pittakall is precipitated from its acetic solution by acid acetate of alumina, whilst eupitton is not. It does not seem probable that Reichenbach was acquainted with eupitton.—*Berichte der Deutsch. Chem. Gesell.*

END-ON ILLUMINATION IN PRIVATE SPECTROSCOPY, AND ITS APPLICATIONS TO BOTH BLOWPIPE FLAMES AND ELECTRIC ILLUMINATED GAS-VACUUM TUBES.*

By PIAZZI SMYTH,
Astronomer Royal for Scotland, and Past President of R.S.S. Arts.

(Continued from p. 163).

PART III.

Electric-Spark Spectroscopy in Vacuum Tubes.

THE next step in spectroscopy, after flame lines, can hardly be anything else than the simple induction spark of electricity in rarefied gas tubes. For the most infinitely small weight of the particles to be moved or heated there, allows a very trifling quantity of electricity, and in uncondensed form, to produce abundantly visible effects. These effects, moreover, supplement in a remarkable manner our knowledge of gases as given by flame experiments. Thus on burning pure hydrogen flamewise in the open air, no spectral effects of lines or bands are seen; because, as it is said, the very act of burning being a combination of that hydrogen with the oxygen of the air, water is formed, and hydrogen ceases to exist as an independent entity. But in a close glass tube filled with hydrogen, the electric spark passing through it, heats that gas by itself alone; and then, not only do we see the hydrogen's spectral lines, but recognise them immediately as some of the most extensively distributed and most important throughout all the universe. For when the populace is in ecstasies at a total solar eclipse, on seeing the red-prominences outside the sun's circumference, and wonders what they are,—the spectroscopist pronounces them to be "flames of incandescent hydrogen of most enormous size."

Again, when the astronomer finds occasionally what is called a new star, or rather an old one which has suddenly become 500 times brighter than before, and must be a sun on fire,—a sun destroying all the life on the planets immediately around it,—it is an immense extravasation of incandescent hydrogen which has done the business. And then we are induced to speculate on whether the similar in kind, though happily smaller in quantity, extravasations, which make the red-prominence round our own sun sometimes large and sometimes small, are, or may be, regulated by cyclical law; and what length of time, if any, may probably separate us from the next of their greater effluxes?

These spectral lines of incandescent hydrogen (four in number, red, glaucous, violet, and a very faint one in the lavender) are therefore rather eerie things to look at; should never be forgotten by man; and may, in the meanwhile, be turned into, and have been already extensively used as, most useful companions at the spectroscopist, through means of the following five inventions, none of them very old.

1st. Prof. Geissler of Bonn introduced the exceeding rarefaction of gases within hermetically sealed glass tubes, armed at each end with platinum wire electrodes.

2nd. Prof. Plucker, also of Bonn, brightened up the light of those tubes by reducing the diameter of the bore of the central part until it was no more than capillary.

3rd. M. Ruhmkorff of Paris improved and vastly reinforced the induction coil.

4th. Dr. Leeson planned the bichromate galvanic battery, with its notable power, and absence of poisonous fumes; and—

5th. Some artist in arrangement produced the long-necked bottle-form of that battery, enabling its power to be called forth at intervals of either minutes, or months, or years, without any intermediate preparation or attention. For mere reference to the first three, and brightest

hydrogen lines, a one-pint bichromate bottle, with a zinc plate 3.0 by 1.5 inches, a small coil giving a $\frac{1}{4}$ -inch spark, and a transverse view are enough, and even more than enough. But for original investigations into the more untoward of the gases for lighting up, far more power and illumination are necessary. To a certain extent, any wealthy observer can obtain that higher degree of illumination most easily, by merely increasing the size of his batteries and coils with the consequent length of their sparks. But then their at-the-same-time growing heat will crack and destroy the tubes so rapidly, that even the richest man may be at last driven to inquire, whether the end-on principle just brought forward, with the claim of increasing brightness without altering the temperature at all, be not applicable?

It is a case for it undoubtedly; for the line of light in a Geissler-Plucker tube is still longer in proportion to its breadth than any blowpipe flame, and usually wastes its precious light in the proportion of 99 to 1. But as these tubes are now made they cannot be employed end-on. Their poles come in the way, two lions at once, totally obscure the view. A very considerable alteration of arrangement is therefore necessary; and not every manufacturer will take the trouble of experimenting for a single private observer. I wrote therefore to my trusty old friend M. Salleron in Paris; and he, with the enthusiasm of a scientist, joined to the practical capacities of a maker of instruments of precision, promptly realised for me one design after another of the end-on gas vacuum tubes, until we at length reached a very promising standard both of size and shape, as thus:—

The new tubes are shorter, broader, stronger than the old ones; more easily manipulated, and safely packed and carried; while, finally, in place of a uselessly long line of faint light, they give a small point of brilliant light. And they are likely to show this for a longer time; as, instead of that point of light (really the axis of the long capillary seen end-on) being looked at through the thick glass walls of the said capillary, which frequently get dimmed inside by oxidising and carbonising effect of the electric heat, they are viewed through the thin walls of the bulbs, whose very large diameter keeps down the heat on themselves and prevents those darkening effects. At the same time all the rest of the glass, except one peep-hole, being silvered externally (and then black-varnished for protection), there is some further increase of brightness by internal reflection.

I show now a box of these tubes whose light, under a standard spark of 1 inch long, may readily be pronounced by eye-view alone, extremely dull if seen *transversely*; but remarkably bright, pungent, and star-like, if looked at *end-on*. The true test is, however, the result of actual spectroscopic observation.

Viewed *transversely*, to the line of electric light, the spectrum of "air," simple atmospheric air, with a prism of 3° dispersion, begins inside the scarlet hydrogen line; and from thence to the lavender-grey, or other end of the spectrum, contains only 72 measurable features, and they of hazy, indistinct, unsatisfactory bands. But viewed *end-on*, the spectrum of the very same air tube, with the same spark and same prism, begins 18 lines or markings outside the scarlet hydrogen; and in the whole spectrum shows 221 measurable items, many of them being vividly sharp lines.

Next, on increasing the prism power to a dispersion of 22° between A and H, but everything else remaining the same, the spectral lines were found so multiplied that 400 were quickly measured in a space where our first attempt had only 38. But I do not claim that all those 400 are truly *air* spectral lines; only that they were lines distinctly seen in a well lighted tube, said to contain chemically the purest possible "air-vacuum." And in fact I stopped where I did, in the green, instead of going on to measure about 1000 more lines that were waiting in the blue and violet, because it presently appeared most indubitably, that some of the lines just entered, instead of belonging

to air in any way, were caused by carbonaceous impurities. In fact I had stumbled, and at the very right time for it on one of the grandest cases of dispute in modern spectroscopy, viz., "Is it carbon vapour, or carbon-compound vapour? carbon by itself, or carbo-hydrogen?" So I immediately increased the prism power 33° between A and H; and then, looking at the minute spectral space, which formed the crucial instance to be measured,—where, just in front of the "green giant," the best leading authority in the "Philosophical Transactions of the Royal Society," London, has only eight lines, and those dark ones,—I there saw most clearly, and measured, 31 lines, and all of them bright ones.

After such an example as that, I need not probably say anything more in furtherance of the principle of the end-on-view kind of gas vacuum tubes. But I would beg leave to call the attention of so practical a meeting as the present, to the facility of manipulating the end-on tubes by means of the peculiar holder for them when under the electric spark; also to the anti-heating character of the large, thin copper plates adopted as terminals for the induction wires, in place of the small brass wire spirals, usually employed; and to the packing-boxes lined with cork and armed with thick grooved cork; all of which have been made for me, and greatly to my satisfaction by, Mr. John Air, of the firm of Air and Candow, cabinet-makers, Leith Walk.

But the vacuum tubes themselves,* including, besides the "air-pure," examples of—

Nitrogen	Carbonic Oxide
Oxygen	Carbonic Dioxide
Ozone	Alcohol
Hydrogen	Marsh Gas
Nitrous Oxide	Olefiant Gas, and
Cyanogen	Ammonia

have all been prepared, as already intimated by M. Jules Salleron, 24 Rue Pavée au Marais, Paris; and so successfully that I do hope he may be encouraged by the patronage of many spectroscopists to apply his rare abilities more extensively to the preparation of similar gas-vacuum tubes for all known chemical volatile products. Indeed I do know that he is ready, according to the prospects which may open up, to have specially infusible glass prepared,† and to organise a system of engraving all the chief data of each tube, as it is made, on the outside of the bulbs, in a manner which must increase confidence of the scientist who uses them afterwards, exceedingly.

Coal-Tar Colours.—Mr. W. H. Perkin, F.R.S., the discoverer of mauve, the first colour produced from coal-tar, is about to read two papers before the Society of Arts on the 8th and 15th of May, in which he will give a full history of these colours, their chemistry and their technical applications.

* Experiments were made first of all as to the best area of a circular bore for the capillary; and proved that there is a *lower* limit which should not be passed if the full, as well as most intense, illumination derivable from any given electric current is to be preserved; and at the same time, there is an *upper* limit of area where the light, though abundant, becomes too faint and diffuse.

Further experiments were then made in flattening the most desirable areas of bore (as so often practised with thermometers), and adapting such flattened bore to the direction of the spectroscope's slit, in order to have a *taller* spectrum. But though the spectrum was thereby made taller, and its lines longer, the author found such bores (on the average of a dozen examples), more often clogged with opaque, adventitious particles; and after a little practice, he did not find the greater length of lines necessary to accurate micrometer observation; while in proportion to such extra length, they waste the light which might otherwise be better employed. Whence he inclines, after all, to circular bores, as more easily manufactured, and more certainly tested as to whether they correspond, or not, to any proposed general standard of size. A standard of compound *shape*, as well as size, is far more difficult to have universally kept to.

† For the ordinary tube-glass, so large an extra-dose of carbonate of soda, I am told, is usually introduced into the melting pot (to promote easy working at low heat and economise coal), that the glass becomes so hygroscopic, and depositions of both water and carbonaceous matter form in the capillaries, and can never be completely cleaned out.

EXTINGUISHING FIRES IN TAR
DISTILLERIES, &c.

By WATSON SMITH, F.C.S., F.I.C.

It may not be known to all tar distillers that in cases of fire on their premises their best remedy usually lies close at hand, and this I will shortly endeavour to demonstrate from a basis of experience and fact. In the first place, however, it may be well to state that as a rule the tar distiller cannot get any fire insurance company to insure him, and it will therefore be seen that it is a matter of no light importance to be possessed of a ready and efficacious method of subduing the dread element, when it breaks out beyond its due bounds. This remedy lies in the crude ammonia-water, otherwise known as gas-liquor, which almost every distiller works up conjointly with the tar, and if in some cases this be not so, it would be little embarrassment, and well worth while, to obtain and keep a stock of, say, 1000 gallons of this gas-liquor. The way in which I first became aware of the eminent extinguishing powers of gas-liquors (now several years ago) is as follows:—A quantity of pitch was being run from a tar-still into the pitch-house, in which it is allowed to stand for some hours, to allow most of the noisome vapours to condense. By some means a flame came in contact with the vapours, an explosion occurred, and in a moment the roof was blown off, and the whole mass of molten pitch ablaze. Water, though thrown on it in quantity, seemed to avail nothing, and at last the supply accidentally ran short. Almost in despair, the pumps for raising the gas-liquor into the ammonia-stills were adjusted so as to deliver a jet of the liquor upon the fiercely-burning pitch: the expedient acted like a charm, and the fire was quickly smothered.

I think there is considerable probability that at the high temperatures attained in some fires even the ammonia itself would be decomposed, with liberation of nitrogen and hydrogen gases, which in addition to the volumes of carbon dioxide and steam, choke out the flame by simple displacement of air. It might be said that if hydrogen and nitrogen be so liberated together, these, together with the H_2S also set free, would do much to neutralise the effect of the non-combustible gases. Not so, however, for let there be but enough incombustible gas present, as there is, to displace the air, or to choke by excessive dilution the little which may remain or diffuse, then the combustible gases present, thus for the time prevented from burning, would assist in smothering the flame (being non-supporters of combustion) with as good a will, if one may use the expression, as the incombustible ones.

I would strongly recommend every tar distiller, who also works up gas-liquor, to so arrange his pumping-gear that he may be able to throw jets of this liquor into any part of his yard or works where fire might break out and prove disastrous. If gas-liquor be not worked, then I would advise that a stock of, say, 1000 gallons be purchased. In a small works this might be advantageously stored in a tank or old boiler mounted on brickwork, at such an altitude as to give pressure enough to furnish a good jet for service below when required. Of course this reservoir should be covered to prevent evaporation.

Looking at the frequent occurrence of disastrous fires in cotton-mills, especially those of Lancashire, I wrote some years ago to an eminent local paper, strongly recommending that the owners of cotton-mills should set tanks on the tops of their mills, and furnish these with supplies of ammoniacal gas-liquor, to be always ready for service. I gave, too, a short description of the best way of arranging pipes to these different rooms. The gas-liquor itself, by careful manipulation, may be pumped off very fairly clear, and free from tarry matter. Of course, besides to fires in cotton-mills and tar-distilleries, this mode of fire-extinction might be all but universally applied. It may, indeed, be readily imagined how a jet of the liquor thrown into a burning room would act, the space being so enclosed, when

the action is so powerful in a comparatively open space, and with such a refractory substance as burning pitch. It would seem, also, that the extinguishing power in the liquor would be even further called forth by a more intensely hot fire, for here, in all probability, the ammonia would be decomposed, and the generated nitrogen and hydrogen gases would help to swell the volume of non-supportive gas, displacing the air, and so choking out the combustion.

A NEW FORM OF WASH-BOTTLE.

By F. R. MALLET,
Geological Survey of India.

In the CHEMICAL NEWS, vol. xxxix., p. 19, Mr. M. H. Foye gives a description of an ingenious form of wash-bottle, the special feature of which is the introduction of a short piece of india-rubber tube in the course of the mouth-tube. By compressing this between the cork and the finger communication is cut off between the mouth and the bottle. The advantages of this are (1) that after blowing into the bottle and then compressing the rubber tube, the pressure of air is sufficient to maintain the jet of liquid for some time; this jet can be instantly stopped

by releasing the rubber tube. (2.) That steam or unpleasant gas is prevented from passing from the bottle into the mouth; and (3) that when pouring liquid out of the mouth-piece the flow can be accurately regulated by pressure on the rubber tube.

On proceeding to make a wash-bottle according to the

instructions given by Mr. Foye, it struck me that, for use with hot or unpleasant liquids, some improvement would be effected by combining Mr. Foye's plan with that of another form of bottle, which is described in Prof. Thorpe's "Quantitative Analysis" (p. 55). The special feature of this latter form consists in the attachment to the bottom of the mouth-tube (*a b*) of a valve, constructed of a piece of rubber tube (*b d*), closed at the lower end by a bit of glass rod (*c d*), and provided with a slit (*e*), which remains closed except when the mouth-piece is blown into.

The advantage of this form of bottle is that unpleasant gases are completely cut off from the mouth-piece (*a*). But there are the defects (1) that it cannot be used for hot water, because the only exit from the bottle being by the jet-piece (*f h i*), as soon as the water approaches the boiling-point the pressure of steam causes it to dribble or squirt out of the jet; and (2) that in the case of cold liquids, after the bottle has been blown into, the jet of liquid continues until the elastic force of the air inside has been expended; hence the jet is not fully under control.

In Mr. Foye's bottle the jet is completely under control. In the case of hot water, however, the mouth-piece (*a*) is the exit for escaping steam, and hence, although this steam can be cut off before applying the lips, the mouth-piece has already been rendered more or less hot. With unpleasant gas, after the rubber tube is closed, the mouth-piece above the rubber tube still contains some of this gas, which is free to enter the mouth. Forgetfulness to remove the lips before releasing the rubber tube will allow gas or steam from the bottle itself also to enter the mouth.

The modified form of bottle that I have adopted is represented in the accompanying sketch. The mouth-piece has the valve (*b d*) attached to the lower end. *f g i* is a jointed jet-piece of the ordinary form, the small glass tube (*i h*) being inserted into the large one (*f h*), with a bit of rubber tube (*g h*) between. *j k* is a third tube, penetrating the cork obliquely, and bent at *k* at an acute angle. A piece of rubber tube (*l*) is, at one end, slipped on to *k* and terminated at the other by a short bit of glass tube (*m*). Outside the rubber tube (*l*) is one of considerably larger diameter (*n*). If such a bottle be used for hot water, the steam escapes from *m*, and hence the mouth-piece (*a*) remains perfectly cool. On compressing the tube *n* with the forefinger and blowing into *a*, a jet issues from *i*, which continues after the removal of the lips until the elastic force of the air in the bottle is expended, but which can be instantly stopped by releasing *n*; the use of the outer tube (*n*) is as a non-conductor. The tube *l* becomes hot from the issue of steam, but *n*, being separated from it by an air space, remains sufficiently cool for the finger to be placed on it without discomfort. A bottle of this sort must, of course, have the neck wound round with twine or other material to keep the hand cool. If the bottle be used for cold liquid only *n* may be dispensed with.

By shifting the valve (*b d*) from the mouth-tube to the tube *j*, the bottle may, if desired, be instantly converted into one on the ordinary plan, or if this be considered unnecessary, the bend of the tube at *j* (which must be made after the tube has been inserted into the cork) may be dispensed with.

For cold water Mr. Foye's bottle is preferable, as liquid can be poured out by the mouth-piece and the flow accurately regulated, which cannot be done with that I have described.

Calcutta, March 27, 1879.

The Government Patent Bill.—A paper on the "Government Patent Bill" will be read before the Society of Arts on Wednesday evening next, the 7th inst., by W. Lloyd Wise, A.I.C.E. F. J. Bramwell, F.R.S., in the Chair.—*Ber. der Deutsch. Chem. Gesell.*

EXPLOSIONS IN FLOUR MILLS.

By H. W. LANGBECK.

IN the *Annales de Chimie et de Physique* there appeared, last year, a communication from L. Smith to Dumas concerning the explosive mixtures of finely-divided organic substances and air, especially of flour and air in some mills at Minnesota. Mr. Smith supposes that meal-dust diffused in the open air was inflamed through the heat produced by the friction of the millstones turning with great rapidity. I think I am justified in opposing that explanation and substituting another one.

Years ago I visited a friend, proprietor of a steam-mill, and there I noticed that the grains crushed between the millstones produced a smell like that of impure hydrogen. I called my friend's attention to the danger that might arise from want of sufficient ventilation, but laughingly he replied that there was nothing to fear. I forgot the matter until the above-mentioned explosion reminded me of it. In order to convince myself of the correctness of Mr. Smith's supposition, I put some meal-dust, previously heated, in a dry bladder, blew air into it, and having diffused the dust by shaking, I directed the point of a gas-flame by means of a blowpipe into the opening of the bladder (an electric spark would have been preferable, but was not at hand). No explosion took place. I allowed, then, coal-gas to enter the bladder, and repeating the experiment, a violent detonation was the expected consequence. Meal-dust diffused in a balloon, and blown through a gas-flame, was ignited; but this was, of course, not the condition on which the explosion at Minnesota took place. But what may be the source of the hydrogen, if indeed present? The amount of fat in wheat flour varies between 1 to 1.9 per cent, of bran 4 to 4.7 per cent, of maize, perfectly dried, 8 to 9 per cent. Is water predisposed to oxidise the fat through heat produced in grinding, thereby setting free hydrogen? Has the change of a small amount of starch into dextrin and glucose during the grinding process something to do with it?

CONVERSAZIONE AT THE ROYAL SOCIETY.

ON Wednesday evening last the President of the Royal Society, Mr. W. Spottiswoode, gave a Soirée at Burlington House, which was largely attended. The novelties exhibited in the various rooms attracted great interest. In the first room were exhibited Mr. Crookes's Exhausted Tubes and Apparatus illustrating various phenomena connected with Molecular Physics in High Vacua. The following is a description of the experiments which were shown:—

1. *Dark Space round the Negative Pole.*—When the spark from an induction coil is passed through an ordinary vacuum tube, a dark space is seen round the negative pole. The shape and size of this dark space do not vary with the distance separating the poles; nor, only very slightly, with alteration of battery power, or with intensity of spark. This well-known dark space appears to be a layer of molecular disturbance identical with the invisible layer of molecular pressure or stress, the investigation of which has occupied the exhibitor some years.

2. *The Electrical Radiometer.*—An ordinary radiometer is furnished with aluminium cups for vanes. The fly is supported by a hard steel cup, and the needle point on which it works is connected with a platinum terminal sealed into the glass. At the top of the radiometer bulb a second terminal is sealed in; the radiometer can therefore be connected with an induction coil, the movable fly being made the negative pole. At low exhaustions a velvety violet halo forms over each side of the cup. On increasing the exhaustion the dark space widens out, retaining almost exactly the shape of the cup; the bright

margin of the dark space becomes concentrated at the concave side of the cup to a luminous focus, and widens out at the convex side. On further exhaustion, the dark space on the convex side touches the glass, when positive rotation takes place.

3. *Green Phosphorescent Light of Molecular Impact.*—At very high exhaustions the dark space becomes so large that it fills the tube, and when German glass is used the sides are beautifully illuminated with a greenish yellow phosphorescent light.

4. *Projection of Molecular Shadows.*—The rays exciting this green phosphorescence will not turn a corner in the slightest degree, but radiate from the negative pole in straight lines, casting strong and sharply-defined shadows from objects which happen to be in their path. The best and sharpest shadows are cast by flat disks, and not by narrow-pointed poles; no green light is seen in the shadow itself, no matter how thin, or whatever may be the substance from which it is thrown.

5. *Magnetic Deflection of the Trajectory of Molecules.*—The stream of molecules, whose impact on the glass is accompanied by evolution of light, is very sensitive to magnetic influence, and the shadow can be deflected by bringing a small permanent magnet near, the amount of deflection of the stream of molecules being in proportion to the magnetic power employed. The trajectory of the molecules forming the shadow is curved when under magnetic influence.

6. *Focus of Heat of Molecular Impact.*—Great heat is evolved when the concentrated focus of molecular rays from a nearly hemispherical aluminium cup is allowed to fall on a strip of platinum-foil, the heat sometimes exceeding the melting-point of platinum.

7. *Mechanical Action of Projected Molecules.*—An actual material blow is given by the impinging molecules. A small vaned wheel being used as an indicator, by appropriate means the molecular shadow of an aluminium plate is projected on the vanes. When entirely in the shadow the indicator does not move, but when the molecular stream is deflected so that one-half of the wheel is exposed to molecular impact it rotates with extreme velocity.

8. *Phosphorogenic Properties of the Molecular Stream.*—Substances known to be phosphorescent under ordinary circumstances shine with great splendour when subjected to the negative discharge in a high vacuum.

(a.) *Becquerel's Luminous Sulphide of Calcium* shines with a bright blue-violet light, and when on a surface of several square inches is sufficient to faintly light a room.

(b.) *The Diamond* is very phosphorescent. Most diamonds from South Africa phosphoresce with a blue light. Diamonds from other localities shine with different colours, such as bright blue, apricot, pale blue, red, yellowish green, orange, and pale green. One large fluorescent diamond gives almost as much light as a candle when phosphorescing in a good vacuum.

(c.) *The Ruby* glows with a rich full red, and it is of little consequence what degree of colour the stone possesses naturally, the colour of the phosphorescence is nearly the same in all cases.

In another room Prof. Guthrie, F.R.S., exhibited Broken Glass in Frames, illustrating the Fracture of Colloids.

In Room V. great interest was taken in the working of the Writing Telegraph, exhibited by Mr. E. A. Cowper. The object attained by this instrument is that it enables the operator to write at a distant station many miles away, just as though he were present there himself, without requiring the use of any special signals, codes, or signs (to spell each letter as is now the practice), and without the assistance of any person to translate the signals as received. The instrument acts upon the simple principle of communicating at all times, to the writing pen at the receiving end of the line, the exact position of the pencil of the operator at the sending station through two line wires, or, so to speak, giving the latitude and longitude of the pencil continually, the position of the pencil vertically being communicated by one wire, and the

position horizontally being communicated by the other wire. The pencil of the operator has two light "contact rods" jointed to it, and one of these slides over the edges of a series of "contact plates," having various resistances interposed between them and the line wire, while the other rod slides over a second set of such plates connected to the other line wire; at the receiving end of the line each of these wires actuates its own needle. The two needles (which are placed at right angles to each other, and are provided with light springs) actuate one writing pen, so that the pen moves up or down, and backwards or forwards, in exact obedience to the motions of the pencil in the hand of the operator at the distant station. Both the paper written upon in pencil by the operator at the sending station and that written upon in ink by him at the receiving station move along as the writing proceeds, and the messages have only to be cut off from time to time, wound round a piece of card and sent out to their destination, or put into an envelope and dispatched.

In the Meeting-Room Edison's Loud-speaking Telephone was exhibited by Mr. Arnold White and Mr. C. P. Edison.

Messrs. Preece and Stroh exhibited a synthetic curve machine, and frame of curves produced thereby. Automatic phonograph. Electro-magnetic vowel-sounder. Stereoscopic curves. Synthetic sounder and syren. Phonautograph.

Mr. J. Browning exhibited a diffraction spectroscope. Automatic spectroscope. Mayall's automatic spectroscope with very dense glass prisms. Automatic sunlight recorder. New bisulphide of carbon prisms. New automatic electric lamp; burns equally well horizontally or vertically.

Mr. A. Hilger exhibited a quartz spectroscope for the ultra-violet rays: constructed for the Scientific Society at Stettin under direction of Dr. Schönn. Universal Christie half-prism spectroscope. New spectroscope, devised by Professors Living and Dewar. Thollon high-power dispersion bottle prism. Hilger's universal variable power prism, from 2° to 10°; collection of different power prisms and pocket spectroscopes; (A to H) dispersion.

Messrs. Tisley and Co. exhibited Tisley's dynamo-magneto machine, with single wire on armature: the alternate currents are used to augment the magnetism and for external work; the armature being hollow is kept cool by a stream of water flowing through. Donkin's harmonograph with parallel and rectangular motions.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, April 26, 1879.

Prof. W. G. ADAMS, President, in the Chair.

Mr. C. V. BOYS gave an account of some experiments made by Dr. Guthrie and himself on the subject of Arago's rotation. The experiments were begun with a view to determine if the drag on a copper disk when a magnet is made to revolve beneath it, or on the magnet if the disk is made to revolve above it, could be made use of for determining the velocity of running machinery. They made the magnet revolve and obtained the angle of deflection of a disk suspended by a torsion thread (the hair spring of a watch.) They found, as Snow Harris and others found before, that other things being equal, the drag is directly proportional to the speed, so that if the torsion of the thread could be relied on, and the strength of the magnet did not change, a perfect velocimeter could be constructed. They consider that this method is better than observing the deflection of a magnet over a revolving disk, as in this case they are limited to less than a right angle, and changes in the absolute magnetism of

the earth would affect the results. They also determined the effect of change of distance, thickness, diameter, and nature of the disk, &c., their results agreeing with those of former experimenters. They observed that the effect of concentric circular cuts was far greater than that of even many radial cuts; and that when radial sectors were entirely separated from each other the effect was much less than when these were united at the centre. They then experimented on liquids by suspending a sphere or cylinder of the liquid between the poles of a revolving electro-magnet, and succeeded in getting a decided and measurable effect. The importance of this is very great, for they have thus a means of determining the conductivity of liquid electrolytes by currents induced in the liquid without the use of electrodes and without polarisation.

Dr. GUTHRIE stated that as the push on the liquid is directly proportional to the current quantity they hope to measure the conductivities of liquids, and connect these to the conductivity of solids through the intervention of mercury.

In reply to Prof. Adams,

Mr. Boys said that the angle of deflection of the conductor had proved to be proportional to its conductivity.

Dr. O. J. LODGE suggested that the conductivity of the disks used in these experiments should be determined by plotting out the equipotential surfaces.

Dr. SYLVANUS THOMPSON recommended trying conducting jellies in these experiments, and

Dr. GUTHRIE replied that such were being prepared for trial, including the permanent jelly made by dissolving gelatine in anhydrous glycerine at 100°.

Prof. SYLVANUS THOMPSON then communicated five laboratory notes from University College, Bristol. The first related to the source of sound in the Bell telephone receiver. Two theories are now being discussed as to this effect, the molar theory regards the motion of the diaphragm in mass as the source of sound; the molecular theory finds it in the molecular motions of the magnetic core of the instrument. Prof. Thompson applied his method of getting magnetic curves with iron filings dusted on gummed glass to this problem. He found that when no currents passed in the telephone the magnetic lines springing from the pole of the magnet are gathered together on the diaphragm opposite, over a central region, which is magnetised lamellarly, or like a magnetic shell. The rim of the plate beyond this region is, however, magnetised radially, and between these two zones there is a neutral circle. It was remarkable, too, that the lines of force touching the plate were bent back around the circle, forming a kind of valley. When the current passed in the coil in a direction so as to reinforce the magnetism, the lines are gathered more closely on the central region of the plate. If the current diminishes the magnetism the lines are, on the other hand, repelled from the plate. The neutral line is also altered. In the first case it shrinks in size, in the second it expands. A small thick disk is wholly magnetised lamellarly; a disk entirely magnetised radially becomes slightly conical in shape. In the actual telephone the disk is flat at the middle and conical at the edges. As the neutral ring shifts the diaphragm will assume new nodal lines. Dr. Thompson concludes that the molecular theory is not, therefore, necessary to account for the speech of the telephone, although it may assist. As confirming this view he found that with iron rings round a cardboard diaphragm and an iron centre piece the enunciation was good, though the *timbre* was altered; whereas with radial pieces of iron on the cardboard the *timbre* was good, but the enunciation bad. In reply to Prof. Adams, Dr. Thompson said that the stronger the magnet the smaller the lamellarly magnetised space became, and that with a thicker disk the neutral ring was not so well marked.

Dr. LODGE suggested that the best place for the coil would be in the valley over the neutral ring, which was in an unstable condition.

Dr. THOMPSON next wrote on a saw blade with a magnet, and dusted iron filings on it, which arranged themselves so as to trace the writing. This is usually shown on a steel plate, but a saw retains the virtue for six or eight months. A modification of this experiment due to himself consisted in writing on the blade with one pole of a powerful battery, the other pole being connected to the end of the blade.

The third "note" recommended the use of fine steel fibres, got by breaking iron gauze of 32 meshes to the inch, instead of iron filings for exhibiting magnetic lines. The fourth note showed that the lines of force got by filings fixed on cards are magnetic, that of a magnet acting as a magnet. The fifth note explained that solid magnetic "figures" could be got by coating iron filings in shellac to make them light, and floating them in water, or by mixing filings in a soft paste of plaster-of-paris, which could be cut into sections on hardening.

CORRESPONDENCE.

NEW FORMS OF APPARATUS.

To the Editor of the Chemical News.

SIR,—Will you allow me, as a reader of your esteemed journal, the CHEMICAL NEWS, to address a few lines to you concerning an article contained in vol. xxxix., p. 160.

The article in question which attracted my attention is that of Mr. M. Benjamin, "On some New Forms of Apparatus," a water-bottle and a burette clamp. I am astonished to see these apparatus described with the predicate of new ones; as when I began my studies as a chemist in the year 1871 they were quite usual things in the eyes of my fellow students. In a great many laboratories this water-bottle is adopted; I only mention the laboratories of the Universities of Leipzig, Bonn, and that of the new Polytechnische Schule of Dresden. But this the distant describer may possibly not know; I therefore draw his attention to the *Zeitschrift für Analytische Chemie*, by Fresenius, where he will find, Vol. II., page 190, from the year 1872, this recently devised apparatus described by H. Fresenius. This description is illustrated by a woodcut, which differs from the one in the CHEMICAL NEWS by only showing the chief parts, the tube through which the water flows and fills the bath to a height, which is determined by a vertical tube through which an excess of water is allowed to flow out. The bath itself is left out in the woodcut, but this may, with very little imagination, easily be added. As to the other new apparatus spoken of in Mr. Benjamin's essay, I will only mention, in a few words, that this is just as old as the first, and even older. It is, and was, to be found in the catalogues of every business of chemical apparatus of some significance, such as Lezbold, Köln, Gehrhardt, Bonn, Noellner, Darmstadt, and I do not doubt that it also is to be found in English and American businesses.—I am, &c.,

DR. FERDINAND KORN.

Renteria, April 16, 1879.
Guizuzcoa Espana.

LOSS OF NITRE IN VITRIOL MANUFACTURE.

To the Editor of the Chemical News.

SIR,—I should have thought, from Dr. Hurter's last reply to me in *Dingler's Journal* and for other reasons, that he would not renew the discussion upon the loss of nitre, at least upon precisely the same lines as those previously taken. But as he thinks fit so to do, and this time before the English public, I am simply compelled to reply to him once more. Those who are further interested in this matter I refer to my explicit refutations of Dr. Hurter's views and

statements in *Dingler's Journal*, vol. cccxviii., pp. 70, 152, and 548.

The principal reason why I have always contended that in the Glover tower no appreciable loss of nitre takes place is this:—That notoriously since the introduction of that apparatus the consumption of nitre in vitriol works, everything else being equal, has not merely been found to be no larger than before—it has actually decreased, and, in some cases, considerably. For instance, it fell from 2.0 to 1.3 parts of nitre to 100 parts of pyrites, according to the figures furnished to me by the manager of one of the best French works, and the fact of that decrease having taken place is not disputed by Dr. Hurter himself in his German papers. But "all fear of appreciable loss of nitre in the Glover tower has vanished now," at any rate, among the general body of vitriol makers, although Dr. Hurter, and possibly a few others, take exception to that view. This I can positively affirm from numerous verbal and written communications of vitriol makers in all principal countries (whom, if need be, I could quote by name); and the fact adduced in my last letter, viz., that some of the most careful manufacturers (e.g., Schaffner of Aussig) introduce all their nitric acid through the Glover tower is a striking proof of the above. Indeed, the all but universal use of the Glover tower is the best practical refutation of the reproach cast upon it by Dr. Hurter, and before him by M. Verster. It therefore requires very weighty and accurately defined arguments to substantiate the statement that an appreciable, let alone a large, loss of nitre takes place in the Glover tower. Has Dr. Hurter produced any arguments of that kind? He estimates the loss of nitre in the manufacture of vitriol from various sources, and lays the unaccounted-for balance to the charge of the Glover tower. It is unnecessary to say how little conclusive such a reasoning process is, for the result is only a margin, arrived at indirectly, and is vitiated by all the errors in estimating the remaining possible sources of loss. It could only be admitted if the latter estimation was in all cases based upon thoroughly reliable data.

For argument's sake, and as I am extremely unwilling to open out any side issue, I will grant Dr. Hurter's statement of the "mechanical losses," amounting to 25 per cent of the nitre, or 1 part of nitre to 100 sulphur.

Coming to the "chemical losses," Dr. Hurter declines to admit any loss of nitre by the oxidation of arsenious acid in the Gay-Lussac tower. Here he is at variance, not merely with the statements of Davis, but also with the very careful investigation of H. Hjelt (*Dingler's Journal*, vol. cccxvi., p. 174). Nor can I agree with him that nitric oxide cannot escape as such, on the ground that it would be re-converted into higher oxides by the excess of oxygen present. That nitric oxide sometimes does occur in the exit-gas, even when working under normal conditions, i.e., with an excess of oxygen, is proved by the ruddy vapours which are formed at the mouth of the chimney, although the "sight" in the exit-pipe is altogether colourless. This is easily explained by the fact that there is not time for the gases to be thoroughly mixed during their rapid transit through the tower, so that in some places free oxygen, and in others NO, may be present.

But now I come to Dr. Hurter's principal fallacy. This is the assumption that the "chemical loss" in the chambers themselves does not exceed 20 per cent of the nitre introduced into the system. But this is the very point to be proved, and such a proof is not even attempted by Dr. Hurter, otherwise than by quoting from Mr. Davis, to whose paper in every other respect he denies any demonstrative power. But here he should most assuredly have maintained his denial with all jealousy; for from Mr. Davis's position it might be inferred that in factories making their acid from brimstone, and working with a nitre-recovery apparatus, next to no loss of nitre should take place, as they have not to contend with arsenic! But here I am able, as I was in my German papers, to turn Dr. Hurter's own arguments against himself. He states the "mechanical losses," and that, as he thinks, with great

exaggeration, at 25 per cent of the nitre; and he declines to admit any "chemical loss" other than that taking place in the Glover-tower or in the chambers. Consequently, in factories working without a Glover-tower, the total loss of nitre could only be 25 per cent of that assumed as the basis of his calculations, viz., 4 parts per 100 of sulphur, that is, 1 part per 100 of sulphur. To this could only be added the amount of nitre lost in the chamber-acid over and above the 10 per cent allowed for already in the above 25 per cent. Mr. Davis found 8.7 and 3.6 per cent of the nitre in undenitrated chamber-acid (leaving out the "only occasionally watched" cases). Dr. Hurter's own statements in *Dingler's Journal* are no use to us here; for they refer to works where, in the first instance, altogether too much nitre was lost (5 per cent of the sulphur), and where, secondly, the very existence of a Glover-tower and the possibility of denitrating the chamber-acid, would, quite properly, cause this to be kept rather more nitrous than where the Guy-Lussac acid is denitrated by steam, and all the nitre contained in the chamber-acid is lost. The only statements referring to the latter case upon which I can lay my hands are the following:—Kolb (*Bull. Soc. Chim.*, 1872, p. 309) states the percentage of N_2O_5 in the "large chamber" (that from which the vitriol is withdrawn for use) = 0.010 per cent, the acid containing 58.6 per cent SO_4H_2 . This is equal to 0.046 N_2O_5 , or 0.100 $NaNO_3$ upon 100 sulphur. He does not state the amount of nitre used, but we may safely assume it at least = 4 per cent of the sulphur, and thus we arrive at only 2.4 per cent of the total nitre as lost in the chamber-acid.

Hasenbach (*Ber. der Deutsch. Chem. Ges.*, vii., p. 681) arrives at a loss of 31 cwts. of nitrate for 60,000 cwts. of vitriol of 66° Baumé, which he states to be about 6 per cent of the total nitre used (it is about 0.19 nitre to 100 sulphur).

Scheurer-Kestner (*Comptes Rendus*, November, 1875), in order to save his platinum stills, keeps his chamber-acid rather sulphurous, and thus practically quite free from nitre; but he has himself stated that his consumption of nitric acid (at 36° Baumé) is 3 per cent of the pyrites, equal to about 4.7 nitre to 100 sulphur. Consequently, if we allow 10 per cent of the nitre as lost in the chamber-acid, also for works without a Glover-tower, we are very much on the right side, according to all authorities. Now this brings our total possible loss, apart from that in the chambers themselves, for works denitrating by steam, to 25 per cent, leaving 75 per cent of the loss to take place in the chambers themselves (whether by Weber's reaction or in any other way), not 20 per cent, as allowed by Dr. Hurter. Thus the big margin claimed by him as chemical loss in the Glover-tower suddenly vanishes into thin air.

I should be the last person in the world wishful to "put a manufacturer off his guard" and "prevent further search" by my statements. But I cannot certainly, on the other hand, run to the opposite extreme, and decline to accept the fact that hitherto no satisfactory proof has been given for any loss of nitre occurring in the Glover-tower, and that all unbiassed evidence goes the other way.—I am, &c.,

GEORGE LUNGE.

Technical Laboratory of the
Federal Polytechnic School, Zürich.

The Wax of *Ficus Gummiiflua*.—F. Kessel.—This wax is a chocolate-coloured mass, which softens when heated and melts between 60° and 70°. Boiling water extracts a considerable quantity of a brown colouring matter, leaving the wax nearly white. Boiling alcohol dissolves considerable quantities of the wax, which on cooling are re-deposited in a white mass resembling cauliflower. By treatment with ether the wax may be separated into two bodies more or less soluble, the former having the composition $C_{15}H_{30}O$ and the latter $C_{27}H_{54}O$. —*Ber. der Deutsch. Chem. Gesell.*

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 13, March 31, 1879.

Conformity of the Systems of Fractures Obtained Experimentally with the Systems of Joints Intersecting the Cliffs of Normandy.—M. Daubrée.—In general these joints form two systems, one of which corresponds to the direction, and the other to the line of the greatest slope.

Convenience of Special Denominations for Different Orders of Fractures of the Crust of the Earth.—M. Daubrée.—The joints, or as he suggests, disjoints, due to rupture, the author would call diaclasses. When the fracture is accompanied by displacement he terms it paraclasses, whilst as a common name for both he suggests litho-clase.

Chemical Researches on a Filamentous Matter found in the Excavations at Pompeii.—S. de Luca.—The filaments in question seem to be carbonised fibres of flax or hemp, and had probably been collected for lint.

Thermic and Galvanometric Laws of the Electric Spark Produced in Gases.—E. Villari.—The heat developed in gases by an electric spark is proportional to the quantity of electricity which produces it. The galvanometric deviations produced by the discharge of Leyden jars are proportional to the quantities of electricity condensed. The galvanometric deviations produced by one and the same charge of the condensers are constant and independent of the length of the spark produced at any given point of the circuit. If one and the same quantity of electricity amassed in any condenser is discharged through a metallic circuit, interrupted so as to give rise to a spark, the quantity of electricity brought into play in the discharge is constant and independent of the length of the spark. The quantity of heat developed in any gas by the electric spark increases in proportion to its length, whence the temperature of the spark at its different points is independent of its length, and the electric resistance of the gases is proportional to the thickness of the gaseous layer traversed by the discharge. When the charge producing the spark remains the same the quantity of heat developed by this spark is independent of the surface of the condenser. In fine, the thermic and galvanometric deviations produced, the former by the spark and the latter by the discharge of a condenser, are proportional to the quantity of electricity which produces them, and at the same time to the length of their active circuits (this name being applied either to the length of the spark or to the length of the galvanometric wire).

Magnetic Rotatory Power of Gases at Ordinary Pressure and Temperature.—H. Becquerel.—By means of a special arrangement which the author describes he has not merely succeeded in showing the magnetic rotation of the plane of polarisation of light at the ordinary temperature and pressure, but has been able to measure it with precision.

Rotatory Magnetic Power of Vapours.—E. Bichat.—On causing the current of eighty large Bunsen elements to act upon a ray of polarised light traversing vapours of carbon sulphide the author has obtained an evident but slight deviation of the plane of polarisation.

Pressure Exerted by Galvanic Deposits.—M. Bouty.—Not suitable for abstraction.

Alkaloids of the Pomegranate.—C. Tanret.—The author finds that pelletierin is accompanied by three other volatile bases, the extraction of which he describes.

Formation of Carbonic Acid, Alcohol, and Acetic Acid in the Presence and Absence of Alcohol.—A. Béchamp.—The same products are generated in either case.

Berichte der Deutschen Chemischen Gesellschaft zu Berlin, No. 17, 1879.

Reductive Action of Milk-sugar upon Alkaline Solution of Copper.—H. Rodewald and B. Tollens.—The authors point out that whilst chemists are agreed on the reductive power of dextrose, there is great discrepancy concerning lactose, 1 mol. of which is considered to represent various quantities of copper oxide, ranging from 64 to 8 atoms. They find that the exact quantity required is 7.47 atoms of copper to 1 mol. of milk-sugar, = 6700 mg. milk-sugar to 1 c.c. of Fehling's liquor. They recommend that this reagent should not be prepared in quantities beforehand; 60 grms. of the best caustic soda and 173 grms. of re-crystallised tartrate of potash and soda are dissolved in $\frac{1}{2}$ litre of water, whilst 34.630 grms. pure copper sulphate are dissolved separately in another half litre. Equal volumes of these two liquids are mixed when wanted.

Oxidation of Xylol-sulphamids.—Ira Remsen.—A reply to a communication by O. Jacobsen, which the author characterises as "almost purely personal."

Formation of Ethylamin.—H. Köhler.—If the black powder produced by agitating calomel with ammonia is heated in a glass tube, through which a current of dry ethyl-chloride is passed, a small quantity of ethylamin is produced.

Certain Colouring Matters of the Rosanilin Group.—E. Fischer and O. Fischer.—If a solution of dimethylanilin in dilute sulphuric acid is mixed with manganese the formation of violet derivatives begins at 30° to 40°.

Meta-nitro-phenol and its Derivatives.—A. Bautlin.—An interesting paper, but not susceptible of useful abstraction.

Certain Greek Tanning Materials.—Hans Jahn.—The author states the average proportion of tannin in the cups of valonias, freed from scales at 22.615 per cent, in the scales at 36.60, and in the entire ware at 33 per cent. Peloponnesian gall-nuts contain on an average 47.6 per cent of tannin; pine-bark from Crete 9.818 per cent, and from Asia Minor 17.285 per cent.

Behaviour of Mono- and Dibrom-acetic Ethyl ethers with Aqueous Ammonia.—F. Kessel.—The author sought to use the behaviour of these bodies with aqueous ammonia as a means for their separation, but succeeded only when the dibrom-acetic ether formed the greater part of the mixture.

Etherification of Secondary Alcohols.—N. Menschutkin.—Not suitable for abstraction.

Cantharic Acid and a Terpenoid Hydrocarbon.—J. Piccard.—Cantharic acid is a powerful mono-basic acid. The author describes the copper and potassium salts, and the origin of cantharic acid, which he considers as formed from cantharic acid by the abscission of carbonic acid.

Gelatinous Silicic Acid and an Inorganic Membrane.—F. Ullik.—The author has found it possible to wash the well-known jelly produced by pouring dilute solution of soluble glass into hydrochloric acid and allowing the mixture to stand. He treats the mass repeatedly with water, taking care not to break it up, and has obtained it free from hydrochloric acid and chlorides, and in the formation of membrane-like layers, which, though incapable of filtering, are capable of dialysing like an animal membrane.

Contributions to the Voluminar and Steric Law.—H. Schröder.—Incapable of abstraction.

Action of Potassium Cyanate upon Epichlorhydrin.—A. L. Thomsen.—The reaction consists in the addition of 1 mol. cyanic acid to 1 mol. epichlorhydrin.

Bulletin de la Société Chimique de Paris,
No. 6, March 20, 1879.

Determination of the Total Nitrogen in Manures.—A. Rémont.—The author, referring to the well-known fact that when a manure contains nitrates the determination of its total nitrogen is impossible, recommends to add to the portion taken for analysis powdered white sugar to the extent of ten times the quantity of the nitrates supposed to be present, basing this approximation on the proportion of soluble matters which the manure contains. (If the manure contains soluble phosphates, salts of potassium, &c., the total soluble matter can throw no definite light on the quantity of nitrates which may be present.) The author adds the somewhat needless precaution that the sugared sample must be mixed with soda-lime before introduction into the combustion-tube lest detonation occur on heating.

Production of Crystalline Chromate of Baryta.—Leon Bourgeois.—Already noticed.

Certain Hydrocarbides formed by the Action of Methyl Chloride upon Toluene in Presence of Aluminic Chloride.—E. Ador and A. Rillet.—This memoir does not admit of useful abstraction.

Bromo-citraconic Acid.—Edme Bourgoin.—This acid, $C_{10}H_6Br_2O_3$, is bibasic, yielding alkaline and earthy alkaline salts of little stability and readily soluble in water.

Relative Affinities and the Reciprocal Displacements of Oxygen and the Halogens.—M. Berthelot.—The author proposes to show that the reciprocal displacements between the halogens and oxygen, united either with the metals or the non-metallic elements, may be predicted according to the sign of the quantities of heat liberated in the formation of the compounds which these elements form with oxygen on the one hand, and with the halogens on the other.

Thermo-chemical Researches on Magnesium, Calcium, Strontium, and Barium.—J. Thomsen.—Along with an increasing atomic weight we find an augmentation in—(a.) The stability of the hydrates and the heat liberated on the hydration of the oxides. (b.) The solubility of the hydrates in water and their heat of solution. (c.) The heat of formation of the chlorides, bromides, iodides, and nitrates. On the other hand, with an increasing atomic weight we find a decrease in—(a.) The affinity of the chlorides, bromides, iodides, nitrates, and sulphates for water; the proportion of water of crystallisation and the heat liberated on its fixation. (b.) The solubility and heat of solution of the same compounds. The atomic weight bears no relation to—(a.) The heat of neutralisation of the dissolved hydrates. (b.) The total heat of formation of the hydrates, i.e., R, O, H_2O .—*Journal f. Praktische Chemie*, xvi., p. 67.

Action of Mono-chloroacetic Acid upon the Sulphocyanates of the Aromatic Monamines.—J. H. Jæger.—Aniline and toluidine, dissolved in alcohol, have been treated with mono-chloroacetic acid along with ammoniac sulphocyanate.—*Fourn. f. Prakt. Chemie*, xvi., 17.

MISCELLANEOUS.

Mr. W. Valentin, F.C.S.—Mr. W. Valentin, F.C.S., is about to retire from the Laboratory of the Science Schools, South Kensington, formerly the College of Chemistry, in connection with which he has laboured for more than twenty years. It would be difficult to find one to whose patient work the present generation of chemists is more indebted, and a few of his old friends and pupils of the Royal School of Mines, recognising the value of his long services, are forming a committee with a view of presenting him with a testimonial. The Committee already includes Dr. Frankland, Dr. Forbes Watson, Prof. Guthrie, Dr. E. J. Mills, and Mr. W. Chandler-Roberts.

Iron and Steel Institute.—The Annual Meeting of the Iron and Steel Institute will be held on May 7, 8, and 9, at the Institution of the Civil Engineers. The programme includes papers and discussions on:—"The Mechanical Properties of Iron and Mild Steel," by Mr. D. Adamson, C.E. "On the Use of Steel in Naval Construction," by Mr. Nathaniel Barnaby, C.B., H.M.'s Chief Constructor. "On the Use of Steel in the Construction of Bridges," by Mr. H. N. Maynard. "On the Elimination of Phosphorus in the Bessemer Converter," by Mr. Sidney G. Thomas, F.C.S., and Mr. Percy C. Gilchrist, A.R.S.M., F.C.S. "On the Removal of Phosphorus and Sulphur during the Bessemer and Siemens-Martin Processes of Steel Manufacture," by Mr. G. J. Snelus, F.C.S., &c. "On a New Volumetric Method of Determining Manganese in Manganiferous Iron Ores, Spiegeleisen, Steel, &c.," by Mr. John Pattinson, F.I.C., Newcastle-on-Tyne. "On a Ready Means of Moulding Lime, and Making Lime or Basic Bricks and Linings for Furnace Converters, &c.," by Mr. Edward Riley, F.C.S., F.I.C., &c. "On a Practical Combination of the Bessemer and Puddling Processes," by Mr. Edwin Pettitt, Cheltenham. "On the Results of Working the Godfrey-Howson Furnaces at the Works of Tamaris, Gard, France," by M. Escalle. "On the Chemistry of Puddling," by Mr. H. Louis, A.R.S.M., Londonderry, Nova Scotia. "On a New Process for Protecting Iron and Steel against Rust," by Prof. Barff.

NOTES AND QUERIES.

Insurance of Tar Distilleries (Reply to W. A. R.).—Though not able to speak positively of the present time, I can certainly aver that a few years ago it was quite impossible to find any fire insurance office willing to grant the protection desired. I think it highly probable that the same state of things still exists, and, what is more, is extremely likely to do so. The tar distiller's best plan is to see to it that he sets such of his plant and materials requiring protection from the weather, under cover of the simplest and least inflammable kind. The tar-stills and other large stills worked with fire usually remain uncovered with any roof. My own experience is that with careful arrangement of plant, and proper precautions and care, there is little need for fear, and, in case of a fire even, this may, except in very exceptional cases, be quickly subdued without much damage being done. See communication on "Extinguishing Fires in Tar Distilleries, &c."—WATSON SMITH.

MEETINGS FOR THE WEEK.

MONDAY, 5th.—Medical, 8.30. (Anniversary)
— Royal Institution, 5. General Monthly Meeting.
— Society of Arts, 8. "Recent Advances in Telegraphy," by W. H. Preece. (Cantor Lectures)
TUESDAY, 6th.—Civil Engineers, 8.
— Royal Institution, 3. "Schumann," by Mr. Ernst Pauer.
— Zoological, 8.30.
WEDNESDAY, 7th.—Society of Arts, 8. "The Government Patent Bill," by W. Lloyd Wise, A.I.C.E.
THURSDAY, 8th.—Royal, 8.30.
— Royal Institution, 3. "Dissociation," by Prof. Dewar.
— Royal Society Club, 6.30.
— Society of Arts, 8. "The History of Alizarin and Allied Colouring Matters, and their Production from Coal-tar," by W. H. Perkin, F.R.S.
FRIDAY, 9th.—Royal Institution, 9. "Habits of Ants," by Sir John Lubbock.
— Astronomical, 9.
— Quekett, 8.
SATURDAY, 10th.—Royal Institution, 3. "Architecture," by Mr. H. H. Statham.
— Physical, 3.

TO CORRESPONDENTS.

E. W.—At the Library of the Commissioners of Patents, Southampton Buildings, Chancery Lane, W.C.
E. W. Young.—Such works as "Watts's Dictionary of Chemistry," "Ure's Dictionary of Arts, &c.," "Gannet's Physics," Wagner's and Richardson and Watts's works on Chemical Technology seem to already supply the information.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1015.

AN EXAMINATION OF DR. PAVY'S METHOD OF DETERMINING GLUCOSE.

By OTTO HEHNER, F.C.S., F.I.C.

THE glowing account given by Dr. Pavy (CHEMICAL NEWS, vol. xxxix., p. 77) of the results obtained in determining glucose by means of ammoniated Fehling solution has doubtless induced many chemists to repeat Dr. Pavy's experiments and to test the accuracy of his method.

120 c.c. of ordinary Fehling solution are mixed with 300 c.c. of strong ammonia (sp. gr. 0.88) and diluted to 1000 c.c. 100 c.c. of this liquid, containing 12 c.c. Fehling solution and capable of oxidising, according to Dr. Pavy, 0.05 grm. glucose, were used in the following experiments instead of 40 c.c., as recommended by Dr. Pavy, in order to obtain results comparable without calculation with those furnished by 10 c.c. of ordinary Fehling solution. The mode of titration was precisely that described by Dr. Pavy.

Following thus Dr. Pavy's directions I was surprised to obtain results widely differing from his, inasmuch as in a long series of experiments I found a difference of about 8 per cent in the total amount of glucose when determining it both by the ordinary copper solution and by the same rendered ammoniacal, the latter furnishing the higher results. In order to obtain corresponding results I had to dilute about 130 c.c. of Fehling solution with ammonia and water to 1000 c.c., instead of 120 c.c. as found by Dr. Pavy.

The copper solution used in these experiments contained 400 c.c. of soda solution (of 1.14 sp. gr.) per litre, and the sugar solution (inverted sugar) was quite neutral; hence there could not possibly be too large a quantity of alkali, against which Dr. Pavy warned in his paper.

I then prepared another quantity of Fehling solution, employing 480 c.c. soda, as recommended by Fresenius. I tested this both without and with the addition of ammonia, by titration with an invert sugar solution, obtained by heating 10153 grms. pure cane-sugar dissolved in 150 c.c. of water, with 10 c.c. strong HCl, on the water-bath, neutralising, and diluting to 250 c.c.

10 c.c. of Fehling solution required 11.70 c.c. sugar solution.

10 c.c. Fehling + 1 grm. NaHO used 11.65 c.c. sugar solution.

"Pavy Solution."	Sugar Solution.
100 c.c. used	11.22 c.c.
" + 0.2 grm. NaHO	11.40 "
" 0.4 "	11.55 "
" 0.6 "	11.71 "
" 0.8 "	11.70 "
" 1.0 "	11.72 "
" 2.0 "	11.90 "
" 3.0 "	12.08 "

The results show quite conclusively that Fehling solution prepared with 480 c.c. of soda of 1.14 sp. gr., corresponding to about 68 grms. NaHO per litre, does not give results concordant with the ratio stated by Dr. Pavy, and also that additions of very small quantities of soda steadily but perceptibly alter that ratio, until 50 grms. of soda per litre have been added to that already contained in the liquid, when further addition of soda, up to more than 80 grms., is without influence. Between these limits, namely with a total of 120 to 150 grms. of soda

per litre, Dr. Pavy's proportion holds strictly good, and then further addition of alkali again increases the oxidising power of the copper solution, but in much smaller proportion than before.

I further gradually diminished the alkali in the copper solution by adding measured quantities of standard acid, the results being as follow:—

Pavy Solution.	Sugar Solution.
100 c.c. — 0.20 NaHO required	11.00 c.c.
" — 0.40 "	10.71 "
" — 0.60 "	10.42 "
" — 0.81 "	8.80 "

Thus it appears that the smaller the quantity of fixed alkali, the smaller also the amount of sugar the copper solution is capable of oxidising; in fact, when no caustic soda at all is present, as in the last of the above experiments, 1 molecule of glucose requires exactly 8 molecules of cupric oxide for oxidation. With ordinary Fehling solution the ratio is 5 molecules; with the same rendered ammoniacal and containing no less than 120 grms. NaHO per litre, 6 molecules; and, lastly, the same without soda, 8 molecules. But the reaction without fixed alkali takes place exceedingly slowly, and on that account the end-point is not easy to hit off.

Instead, therefore, of guarding against too large a quantity of alkali, it is of far greater importance to avoid a deficiency, and good results can only be obtained by doubling the quantity of soda usually taken in the preparation of the cupro-tartrate solution. On the other hand, a much smaller excess of soda influences the result than is stated by Dr. Pavy, who found an addition of 5 grms. to 100 c.c. of the ammoniacal solution, or 417 grms. to the litre of Fehling solution without influence, whilst my results, which I have verified over and over again, show that even 2 grms. to 100 c.c. of the ammoniated solution, or 166 to the litre of Fehling, show a small but quite perceptible alteration. Thus the limits of alkali allowable or necessary are not so wide as might appear.

If the proportions given by me are adhered to, the method is capable of furnishing excellent results. The solution containing the glucose should be added drop by drop to the ammoniacal copper solution, kept gently simmering. The end-point of the reaction is beautifully sharp, and titrations of the same liquid will never differ by more than 0.1 c.c. of the sugar solution. The action is, however, somewhat slower than with ordinary Fehling liquid. By suitable arrangements the ammonia can readily be absorbed and any nuisance avoided which would result from its entering the atmosphere.

It must not, however, be taken for granted that the ratio holding good between the ordinary and the ammoniated copper solution is valid also in the case of other reducing saccharine matters. Dextrose and lævulose act equally, but I find that both milk sugar and maltose possess entirely different reducing power against two kinds of copper solutions.

Thus a solution of pure milk-sugar acted as follows:—

10 c.c. ordinary Fehling solution required	16.76 c.c.
100 c.c. Pavy solution	20.76 "

The ratio is therefore just contrary to that resulting by the action of glucose. The titration of milk-sugar, difficult and unsatisfactory as it is with the ordinary Fehling test, is, however, still more readily influenced by dilution, quantity of alkali, and rate of addition, and hence still less trustworthy in ammoniacal solution. Its action on that solution is very slow, and the end-point is somewhat difficult to observe, because on the experiment being much protracted cuprous oxide deposits and obscures the colour of the liquid.

Maltwort acts similarly to milk-sugar, proving that it does not contain glucose, but another sugar, doubtless maltose. Experiments in reference to this matter are in progress.

54, Holborn Viaduct, London, April 12.

RECENT CONTRIBUTIONS TO THE HISTORY
OF DETONATING AGENTS.*

By Professor ABEL, C.B. F.R.S.

(Continued from p. 188.)

It will now be evident why the readily yielding nature of the particles of liquid nitro-glycerine tends to counteract its great sensitiveness to detonation, and why, when the motion of the liquid particles is impeded by their admixture with solid matter, and when they are consequently placed in a position to resist mechanical motion by the force applied through the agency of detonation, its natural sensitiveness to detonation, and the rapidity with which it can be transmitted from particle to particle became fully developed.

Again, the reduction of gun-cotton fibre to a fine state of division, which renders the material readily convertible into very compact and dense masses, places the particles in the condition most favourable to resist mechanical motion upon the application of a blow, or of the concussion resulting from a detonation; hence, compressed gun-cotton is readily susceptible of detonation in proportion to the extent of compression, or to its density and compactness, while loose gun-cotton wool, or the lightly twisted or compressed material, cannot be readily detonated, because the force applied is expended in imparting motion to the readily yielding particles of the mass. If the force applied through the agency of a detonator to a mass of explosive material just borders upon that required for the development of the detonation, or if the condition of the mass is such as hardly to present the requisite resistance to mechanical motion essential for its detonation, then results intermediate between the mechanical dispersion of the mass and its violent chemical dispersion or disintegration, *i.e.*, detonation, are obtained. Thus frequent instances have been observed, especially in the experiments in the transmission of detonation through tubes, in which the initiative detonation has brought about an explosion attended with little, if any, destructive effect, portions of the mass being at the same time dispersed and occasionally inflamed. Not only have such results often been obtained with gun-cotton and dynamite, but even mercuric fulminate, exposed to the concussion of a distant detonation transmitted through a tube, has frequently been exploded in a manner quite distinct from the violent detonation developed in other instances. Silver fulminate, which under conditions detonates violently, even when only a particle of the mass is subjected to a sufficient disturbing influence, has been exploded without the usual demonstrations of force, by the transmitted effect of a detonation of mercuric fulminate. In these instances the violence of the concussion produced by the initiative detonation was only just bordering on that required for the development of detonation, and it appears probable that only some small portion of the mass operated upon was in a condition or position favourable to the action of the initiative blow. The remainder of the mass would then be dispersed by the gases developed from the detonated portion; in some instances the particles would be inflamed at the moment of their dispersion, in others they would even escape ignition. The latter appears to be always the case when gun-cotton is exploded by a blow from a hammer or falling weight. However carefully the arrangements are adjusted with a view to distribute such a blow uniformly over the entire mass struck, the concentration of a preponderance of the force applied upon some portion or portions of the entire mass, appears almost inevitable; hence only a small portion is actually detonated, the remainder being instantaneously dispersed by the gases suddenly generated while the weight is still resting upon the support.

Some experiments made in firing at masses of compressed gun-cotton, differently arranged and of different

thicknesses, with a Martini-Henry rifle, at short ranges, afforded interesting confirmation of the correctness of the explanation given of the operation of a blow upon masses of explosive material under different conditions. Disks of gun-cotton of the same density and diameter, but differing in thickness, were fired at; they were freely suspended, and their distance from the marksman was in all instances 100 yards. The thinnest disks were simply perforated by the bullets, not a particle of the gun-cotton being ignited. Somewhat thicker disks were inflamed by the impact of the bullet, while still thicker disks, fired at under the same conditions, were exploded, portions being in some instances dispersed in a burning state. No instance of detonation was, however, obtained. These differences in effect, obtained with masses of different thickness and weight, are due to the difference in their power to resist mechanical motion when struck by the bullet, and in the different amount of resistance to penetration presented by the thin and the thicker disks.

It has been explained that nitro-glycerin may be largely diluted with inert solid matters without the sensitiveness to detonation being reduced, while its detonation in open air becomes very much facilitated, because the mobility of the particles, and their consequent tendency to yield to the force of a blow or detonation, is very greatly diminished. But if a *solid* explosive agent is diluted with inert *solid* matter the case is different; for in such a mixture of the finely divided solid with non-explosive solid particles, there must be a partial and sometimes a complete separation of the particles of the explosive by the interposed inert particles with which it is diluted; hence the sensitiveness to detonation is reduced, and its transmission by the particles is retarded or altogether impeded, by a diminution of the extent of contact between the substance to be detonated and the initiative detonation, and by the barrier which the interposed non-explosive particles oppose to the transmission of detonation. Thus a mixture of mercuric fulminate with more than one-fifth its weight of French chalk could not be detonated by means of one grain of pure fulminate enclosed in a copper capsule, which was inserted into the mixture; that quantity, similarly confined, sufficed to detonate undiluted fulminate through a tube 8 inches long and 0.5 inch in diameter. In experiments made in this direction with finely divided gun-cotton, it was found that although dilution was an inert solid, applied in the *solid form*, reduced the sensitiveness of the material to detonation, this was not the case when it was incorporated with a salt soluble in water, the mixture being then compressed while in the wet state. The compressed masses thus obtained were, when dried, in a condition of greater rigidity than could be attained by submitting undiluted gun-cotton to considerably more powerful pressure, because the crystallisation of the soluble salt used as the diluent upon evaporation of the particles, cemented the particles composing the mass more rigidly together. The gun-cotton was therefore presented in a form more capable of resisting the mechanical action of a small charge of fulminate than a more highly compressed undiluted gun-cotton, and hence the reduction in sensitiveness due to the detonation of the explosive compound is nearly counterbalanced by the greater rigidity imparted to the mass. If a soluble oxidising agent (a nitrate or chlorate) be employed as the diluting material, the predisposition to chemical reaction between it and the gun-cotton (which is susceptible of some additional oxidation), appears to operate in conjunction with the effect of the salt in imparting rigidity to the mixture, thus rendering the latter quite as sensitive to the detonating action of the minimum fulminate charge as undiluted gun-cotton. Moreover, the interesting fact has been conclusively established that these compressed mixtures of gun-cotton with a nitrate or a chlorate are much less indifferent to the influence of detonating nitro-glycerin than gun-cotton in its pure state. Chlorated and nitrated gun-cotton are detonated with certainty by means of $\frac{1}{2}$ oz. of nitro-glycerin, whereas the detonation of 2 ozs. of the latter

* Abstract of a Paper read before the Royal Institution of Great Britain, Friday, March 27, 1879.

accomplished the detonation of ordinary compressed gun-cotton only once in a large number of experiments.

If compressed gun-cotton is diluted by impregnating the mass with a liquid, or with a solid which is introduced into the mass in a fused state, its susceptibility of detonation is reduced to a very much greater extent than by a corresponding quantity of a solid inert body, incorporated as such with the gun-cotton, the cause being the converse of that which operates in preventing a reduction of the sensitiveness to detonation of nitro-glycerin by its dilution with an inert solid. In this case the explosive liquid envelopes the solid diluent, and remains continuous throughout, occupying the spaces which exist between the solid particles; hence detonation is readily established and transmitted. But in the case of the solid explosive, the diluent, which is liquid, or at any rate is introduced into the mass in the liquid state, envelopes each particle of the solid, so that a film of inert material surrounds each, isolating it from its neighbours, and thus opposing resistance to the transmission of detonation, which is proportionate to the original porosity or absorbent power of the mass.

While compressed gun-cotton, in the air-dry state, is detonated by 2 grains of mercuric fulminate imbedded in the material, its detonation by 15 grains, applied in the same manner, becomes doubtful when it contains 3 per cent of water, over and above the 2 per cent which exists normally in the air-dry substance. Specimens which had been impregnated with oil or soaked in melted fat and allowed to cool could not be detonated by means of 15 grains of fulminate. These diluted samples of gun-cotton could only be detonated by adding very considerably to the power of the initiative detonation; 100 grains of confined fulminate generally failed to detonate gun-cotton containing from 10 to 12 per cent of water, and if the amount reached 17 per cent, 200 grains of fulminate were needed to ensure its detonation.

But moist or wet compressed gun-cotton is decidedly more susceptible of detonation by (dry) compressed gun-cotton itself than by mercuric fulminate.

Thus 100 grains of dry gun-cotton, detonated through the agency of the ordinary fulminate fuze, suffice to detonate wet gun-cotton containing 17 per cent of water, though this result is somewhat uncertain. If the diluting agent amounts to 20 per cent, detonation is not certain with less than 1 oz. of dry gun-cotton, and if the compressed material be completely saturated with water (*i.e.*, containing 30 to 35 per cent) 4 ozs. of the air-dry substance, applied in close contact, are needed to ensure its detonation.

Detonation is transmitted through tubes from dry compressed gun-cotton to a moist disk of the material with the same facility as to the dry substance; and this is also the case with regard to the propagation of detonation from one mass of moist gun-cotton to another, in open air, all the pieces being ranged in a row, in contact with each other, provided that the piece first detonated does not contain less water than the others to which detonation is transmitted. Some curious results, obtained in experiments on the transmission of detonation, with gun-cotton containing different proportions of water, appeared to indicate that the character or quality of detonation developed by gun-cotton is subject to modification by the proportion of water which the latter contains.

Gun-cotton containing 12 to 14 per cent of water is ignited with much difficulty on applying a highly heated body. As it leaves the hydraulic press upon being converted from the pulped state to masses having about the density of water, it contains about 15 per cent of water; in this condition it may be thrown on to a fire or held in a flame without exhibiting any tendency to burn; the masses may be perforated by means of a red-hot iron or with a drilling tool, and they may with perfect safety be cut into slices by means of saws revolving with great rapidity. If placed upon a fire and allowed to remain there, a feeble and transparent flame flickers over the surface of the wet

gun-cotton from time to time as the exterior becomes sufficiently dry to inflame; and in this way a piece of compressed gun-cotton will burn away very gradually indeed. A pile of boxes containing in all 6 cwts. of gun-cotton, impregnated with about 20 per cent of water, when surrounded by burning wood and shavings in a wooden building, was very gradually consumed, the gun-cotton burning as already described when the surfaces of the masses became partially dried. In two other experiments quantities of wet gun-cotton of 20 cwts. each, packed in one instance in a large, strong wooden case, and, in the other, in a number of strong packing cases, were placed in small magazines, very substantially constructed of concrete and brickwork. Large fires were kindled around the packages in each building, the doors being just left ajar. The entire contents of both buildings had burned away, without anything approaching explosive action, in less than two hours. This comparatively great safety of wet gun-cotton, coupled with the fact that its detonation in that condition may be readily accomplished through the agency of a small quantity of dry gun-cotton, which, through the medium of a fulminate fuze or detonator, is made to act as the initiative detonating agent, gives to gun-cotton important advantages over other violent explosive agents for purposes which involve the employment of more or less considerable quantities at one time, on account of the comparative safety attending its storage and the necessary manipulation of it. Moreover, it has been well established by experiments of many kinds carried out on a considerable scale, as well as by accurate scientific observations, that the detonation of wet gun-cotton is decidedly sharper or more violent than that of the dry material; a circumstance which affords an interesting illustration of the influence exerted by the physical condition of the mass upon the facility with which detonation is transmitted from particle to particle. In the determinations made by means of the Noble chronoscope, of the velocity with which detonation is transmitted along layers or trains of gun-cotton and nitro-glycerin, the lecturer has included experiments with gun-cotton containing different proportions of water. When the material contained 15 per cent of the liquid, some indications were obtained that the rate of transmission of detonation was a little higher than with dry gun-cotton; the difference was very decidedly in favour of wet gun-cotton, when the latter was thoroughly saturated with water. (With air-dry gun-cotton the mean rate of transmission ranged in several experiments between 17,000 and 18,900 feet per second; with gun-cotton containing about 30 per cent of water, the mean rate of transmission ranged between 19,300 and 19,950 feet per second.) The air in the masses of compressed gun-cotton being replaced entirely by the comparatively incompressible body, water, the particles of explosive are in a much more favourable condition to resist displacement by the force of the detonation, and hence they are more readily susceptible of sudden chemical disintegration. Moreover, the variations in the rate of travel of detonation in dry gun-cotton, resulting from differences in the compactness or rigidity of different masses of the material, are very greatly reduced, if not entirely eliminated, by saturating the disks with water and thus equalising their power of resisting motion by a sudden blow.

Another striking illustration of the influence which the physical character of an explosive substance exercises over its susceptibility to detonation and the degree of facility with which its full explosive force is developed, is furnished by one of the most recently devised, and one of the most interesting of existing, explosive agents.

Twelve years ago, soon after the process of producing compressed and granulated gun-cotton had been elaborated by the lecturer, it occurred to him to employ these forms of gun-cotton as vehicles for the application of nitro-glycerin. A considerable proportion of the liquid was absorbed by the porous masses of gun-cotton, and a nitro-glycerin preparation analogous in character to dynamite was

thus obtained. The absorbent was in this case a violently explosive body instead of an inert solid as in dynamite, but the quantity of nitro-glycerin in a given weight of the preparation (to which the name of *Glyoxilin* was given), was considerably less than in the Kieselguhr-preparation; hence the latter was nearly on a point of equality with it, in regard to power, as an explosive agent.

Nobel has observed that if, instead of making use of the most explosive form of gun-cotton, or trinitro-cellulose, a lower product of nitration of cellulose (the so-called soluble or colloid gun-cotton) is added to nitro-glycerin, the liquid exerts a peculiar solvent action upon it, the fibrous material becoming gelatinised while the nitro-glycerin becomes at the same time fixed, the two substances furnishing a product having almost the characters of a compound. By macerating only from 7 to 10 per cent of soluble gun-cotton with 90 to 93 per cent of nitro-glycerin, the whole becomes converted into an adhesive plastic material, more gummy than gelatinous in character, from which, if it be prepared with sufficient care, no nitro-glycerin will separate even by its exposure to heat in contact with bibulous paper, or by its prolonged immersion in water, the components being not easily susceptible of separation even through the agency of a solvent of both. As the nitro-glycerin is only diluted with a small proportion of a solidifying agent which is itself an explosive (though a somewhat feeble one), this *blasting gelatine*, as Nobel has called it, is more powerful not only than dynamite but also than the mixture of a smaller quantity of nitro-glycerin with the most explosive gun-cotton, as the liquid substance is decidedly the most violent explosive of the two. Moreover, as nitro-glycerin contains a small amount of oxygen in excess of that required for the perfect oxidation of its carbon and hydrogen constituents, while the soluble gun-cotton is deficient in the requisite oxygen for its complete transformation into thoroughly oxidised products, the result of an incorporation of the latter in small proportion with nitro-glycerin is the production of an explosive agent which contains the proportion of oxygen requisite for development of the maximum of chemical energy by the complete burning of the carbon and hydrogen, and hence this *blasting gelatin* should, theoretically, be even slightly more powerful as an explosive agent than pure nitro-glycerin.

That such is the case has been well established by numerous experiments, but although this *blasting gelatin* may be detonated like dynamite by means of small quantities of confined detonating composition, when it is employed in strongly tamped blast-holes, or under conditions very favourable to the development of great initial pressure, it behaves very differently from that material, or other solid though plastic preparations of nitro-glycerin, if the attempt is made to detonate it when freely exposed to the air or only partially confined. It not only needs a much more considerable amount of strongly confined detonating composition than dynamite and similar preparations do, to bring about a detonation with it under those conditions; but when as much as 15 or 20 grains of confined fulminate are detonated in direct contact with it, although a sharp explosion occurs, little or no destructive action results, and a considerable portion of the charge operated upon is dispersed in a finely-divided condition. This dispersion appears to take place to some slight extent with dynamite also, when a small charge is detonated in open air, in consequence of its want of rigidity, though the amount of explosive which thus escapes detonation is very small as compared with the gelatin.

(To be continued.)

Temper of Steel.—M. Jarolimek maintains that steel can not only be hardened by immersion in boiling water, but even in boiling oil, melting lead, and melting zinc.—*Moniteur Scientifique.*

EXHIBITION OF ELECTRIC LIGHTING APPARATUS AT THE ROYAL ALBERT HALL.

ON Wednesday evening last an Exhibition of Electric Lighting Apparatus at the Royal Albert Hall was inaugurated by a lecture on the electric light, which was given by Mr. W. H. Preece, M.Inst.C.E., in the presence of the Prince of Wales, the Duke of Edinburgh, Prince Christian, and the Duke of Teck. Among the visitors were Lord Lindsay, Lord Rayleigh, Sir F. Pollock, Sir Charles Bright, Dr. Lyon Playfair, C.B., F.R.S., Dr. De la Rue, F.R.S., Prof. Tyndall, F.R.S., Prof. Abel, C.B., F.R.S., Dr. William Siemens, F.R.S., Dr. Frankland, F.R.S., Mr. Crookes, F.R.S., Mr. J. N. Lockyer, F.R.S., Prof. Ayrton, &c.

After the Prince of Wales had taken a seat on the right of the orchestra, the Duke of Edinburgh advanced to the front of the platform, and as Senior Vice-President of the Council of the Albert Hall introduced the Lecturer, who began by demonstrating that all systems of artificial illumination are dependent upon the production of heat. Some brilliant experiments were introduced to show that the greatest concentration of heat can be produced by electric currents in overcoming resistance. When this resistance is the air itself the electric arc is the result: when it is a wire or carbon rod we have light by incandescence. The discussion at the present time was whether light by the arc or by incandescence is to be the light of the future. The arc gives two and a half times the intensity of light given by incandescence by the same power. Mr. Preece showed that the improved methods now employed for the production of electricity by mechanical means is due to the development of Faraday's discovery that electric currents are produced by the rapid rotation of coils of wire in a powerful magnetic field, Faraday's original apparatus for showing this being exhibited by the Royal Institution. The electric light dependent on incandescence was practically illustrated by the lamps of Werdermann and the Anglo-American Light Company. That dependent on the arc was shown by the regulators of Serrin, Siemens, Rapieff, and Wallace. The form of light based on the arc, but independent of regulators, called the candle, was illustrated by those of Wilde and Jablochhoff. Mr. Preece also introduced to the audience a powerful lamp called the "holophote," which is about to be introduced into the ports at Spithead, with a view to testing their value in detecting the advance of an enemy's torpedo. The many shortcomings of the electric light—such as the noise, the flickering, the deep shadows—were referred to, as well as such advantages as the absence of smoke, and the purification instead of the poisoning of the air in large buildings. The electric light was pronounced to be at the present time in the tentative stage, there being, as Mr. Preece remarked, three stages of every physical invention—the theoretic, when it is the dream of the philosopher; the tentative stage, when it is the dream of the capitalist; and the third stage, when the practical man realises these dreams.

The lecture was very warmly applauded. At its conclusion the Duke of Edinburgh proposed, on behalf of the Council of the Royal Albert Hall, a vote of thanks to Mr. Preece for his lecture. In the course of his speech His Royal Highness said that the Council of the Royal Albert Hall was anxious to employ the electric light even in its present imperfect condition in lighting the building, and would persevere until something satisfactory was accomplished. The vote of thanks was seconded by His Royal Highness the Prince of Wales.

The Exhibition will remain open until Saturday, and on Friday evening, at 8 o'clock, an explanatory lecture will be given by Mr. J. N. Shoolbred. The Council has endeavoured to make the collection of apparatus embrace the entire scope of all applications into which electric light strictly enters; and also as completely represents

tive as possible of all the various methods hitherto devised for the production of the electric light by mechanical means.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, May 1, 1879.

Dr. WARREN DE LA RUE, President, in the Chair.

THE minutes of the previous meeting were read and confirmed. The following certificate was read for the first time:—J. Sakurai.

THE PRESIDENT then called on Dr. W. RAMSAY to read a paper "*On the Volumes of Liquids at their Boiling-points obtainable from Unit Volumes of their Gases.*" Kopp, in 1855, pointed out that the specific gravities of organic compounds show a certain regularity with regard to each other. If the molecular weights of various compounds be divided by their respective specific gravities at their boiling-points, a series of numbers is obtained, which Kopp ultimately named specific volumes. Kopp's method of determining the volume of a liquid at its boiling-point (the only point at which volumes are comparable, for at that point the vapour-tensions of all liquids are equal) was to ascertain the boiling-point with great accuracy, to determine the specific gravity of some known temperature, and calculate the volume required by means of the coefficient of expansion. This process involves the use of complicated and expensive apparatus, and necessitates laborious calculation. Before describing the apparatus used by himself, the author discusses the precise conceptions involved in the expressions used by Kopp, &c.—"Atomic volume," "molecular volume," and "specific volume:" specific volume as used by Kopp =

$$\frac{\text{molecular weight}}{\text{specific gravity}}$$

By molecular weight is meant the specific gravity of the gas, hydrogen at 0° being equal to 1; specific gravity water = 1; so that two scales are employed, viz., one based on H₂ as unity, and one based on water. The number obtained from the above equation, therefore, does not give the relation between the volumes and weights of liquids at their boiling-points and that of the gases obtainable from those liquids. To obtain this relation, the number representing the specific gravity of the liquid must be multiplied by the number which represents the relation between the specific gravity of water and that of hydrogen, i.e., 22.326. By reversing Kopp's process, i.e., by dividing the sp. gr. of the boiling liquid by that of the gas, the amount of gas obtainable from unit volume of the liquid is calculated. Thus, specific volume of liquid hydrogen

= 5.5, and its sp. gr. is $\frac{1}{5.5}$ or 0.1818, and $0.1818 \times 22.326 = 4.0592$, the sp. gr. of liquid hydrogen (hydrogen gas = 1). By dividing the sp. gr. of gaseous hydrogen by that

of liquid hydrogen, or $\frac{1}{5.0592}$ we get 0.0024635 as the volume of liquid obtainable from 1 volume of gas, or 2.46 from 10,000 vols. of gas. This number (2.46) the author proposes to call "ebullition volume." Kopp's numbers give the amounts of boiling liquids obtainable from 22.326 vols. of gas at 0°. The apparatus used by the author consists of a thin glass bulb of about 10 c.c. capacity, in shape like a lemon: its upper end is terminated by a hooked capillary tube, and its lower end is closed, and furnished with a glass hook. The capacity is accurately determined by filling with boiled distilled water and weighing. To determine the weight of a known volume of a liquid at its

own boiling-point, the bulb is filled with the liquid, and suspended by a platinum wire in a glass vessel resembling a large test-tube, having a bulb blown about half an inch from the bottom. A small quantity of the liquid is placed in this glass flask, and the bulb suspended by a platinum wire from the cork which fits in the upper part of the flask. The liquid in the flask is caused to boil by a small Bunsen flame: the vapour heats the bulb, the liquid in it expands, and drops are expelled from the capillary tube. As soon as the drops cease to fall, usually in about ten minutes, the bulb and its contents have assumed a temperature equal to the boiling-point of the liquid. The bulb is withdrawn, allowed to cool, and weighed. Various precautions must be taken with liquids which are very volatile or oxidisable. Allowance is carefully made for the expansion of the glass. The time required for one determination is about half an hour. The author has made many determinations with a great variety of substances. His results, on the whole, agree very closely with those obtained by Kopp. The value of some of the elements seems to vary much. Thus, oxygen has two values, 3.49 and 5.45; sulphur 10.27 and 12.79. Nitrogen in amines is 2.3; in cyanogen compounds, 1.7; in bodies containing NO₂, 1.74 (Kopp). The author has determined the ebullition volume of some of the pyridine series of bases, e.g., in picoline, value of N = 4.08; in its isomeride aniline, N = 2.11; in pyrrol N = 9.12. From its volume it appears to belong to the cyanogen group. In conclusion, the author draws attention to the enormous differences between these values of N, and suggests a connection between values and the amounts of heat evolved in the formation of these substances.

The next paper was read by Mr. J. PATTINSON, "*On a Method of Precipitating Manganese entirely as Dioxide, and its Application to the Volumetric Determination of Manganese.*" Many methods of determining manganese volumetrically have been suggested, but none have come into general use, owing principally to the difficulty of obtaining the whole of the manganese in a definite and uniform state of oxidation. The author has examined the methods suggested by Pereno and Lenssen, but did not succeed in obtaining regular results. Wright and Luff have also been unable to obtain pure manganese dioxide by any of the ordinary methods. After numerous experiments the author found that the whole of the manganese in a solution of manganous chloride could invariably be precipitated in the condition of dioxide, if a certain amount of ferric chloride be present, by a sufficient excess of a solution of calcium hypochlorite or bromine water, adding, after heating the solution to from 140° to 160° F., an excess of calcium carbonate, and then well stirring the mixture. Without the ferric salt the precipitation as MnO₂ is imperfect. Zinc chloride may be substituted for ferric chloride, but neither aluminium nor barium chlorides have the same desirable effect. The author recommends the following solutions, &c.:—The clear liquid obtained by decantation from a 1.5 per cent solution of bleaching-powder; light granular calcium carbonate obtained by precipitating an excess of calcium chloride by sodium carbonate at 180° F.; a 1 per cent solution of ferrous sulphate in dilute (1 in 4) sulphuric acid; standard solution of potassium dichromate equivalent to 1 part of iron in 100 of solution. The application of the process to manganiferous iron ores is as follows:—10 grains of the ore, dried at 212°, are dissolved in a 20-oz. beaker in about 100 fluid grains of hydrochloric acid (sp. gr., 1.18). Calcium carbonate is then added until free acid is neutralised and the liquid turns slightly reddish. 6 or 7 drops of HCl are now added, and 1000 grains of the bleaching-powder solution, or 500 grains of saturated bromine-water, and boiling water run in until the temperature is raised to 140° to 160° F.; 25 grains of calcium carbonate are added, and the whole well stirred. If the supernatant solution has a pink colour, the permanganate is reduced by a few drops of alcohol. The precipitated oxides of iron and manganese are filtered off and washed. 1000 grains of the acidified ferrous sulphate

solution are carefully measured into the 20-oz. beaker already used; the filter with its washed contents added. A certain quantity of the ferrous sulphate is oxidised by the MnO_2 ; this quantity is estimated with the standard dichromate solution, when the quantity of MnO_2 can easily be calculated. The iron present must be at least equal in weight to the manganese during the precipitation in order to ensure the absence of lower oxides. The author gives in detail the slight modifications necessary in the analysis of spiegeleisen, ferro-manganese steel, and manganese slags; also some analyses which prove the accuracy of the process.

Dr. WRIGHT was extremely interested in the paper, especially as to the action of the ferric chloride. He asked if Mr. Pattinson had found any substances which acted in the opposite way, i.e., decreased the yield of MnO_2 .

Mr. PATTINSON said that all his efforts had been directed to ensure the complete formation of MnO_2 .

The PRESIDENT then called on Mr. WARINGTON to read a paper "On the Determination of Nitric Acid as Nitric Oxide by means of its Action on Mercury." During the last two years the author has used this method to a considerable extent: it was first suggested by W. Crum, and has been much improved by Frankland. The author has in the main carried out the process as recommended by Thorp in Sutton's "Volumetric Analysis." He did not, however, expel any gas which might be liberated before shaking. In the presence of some kinds of organic matter a permanent froth was at some times produced. This could be destroyed either by the introduction of a little hot water through the stopcock, or by gently warming the liquid in the inclined tube by a small flame. A considerable number of experiments are given as to the effect of chlorides on the accuracy of the results obtained in estimating nitrates, nitrites, and the nitric acid in soils. The author finds that the results are quite as satisfactory, even when chlorine is present in a quantity equal to eight times the equivalent of the nitrogen, and concludes that chlorides, except perhaps in extreme cases, are no hindrance to the accurate determination of nitric and nitrous acid by this method, and that it is unnecessary to remove them by previous treatment with sulphate of silver. The author then investigated the influence of organic matter, and finds that organic matter in quantities likely to be met with affect the results but little; cane-sugar, however, has a remarkable action in preventing the complete evolution of the nitric oxide. In some cases a considerable quantity of gas was evolved, without shaking; this gas was found to be nitric oxide, the action taking place between the nitric acid and organic matter instead of between nitric acid and mercury. It is obvious that a considerable error would be caused by expelling any gas liberated before shaking in such cases. Commercial glucose has a considerably less injurious effect than cane-sugar. It is interesting to observe that chlorides, if present, seem to prevent to a great extent the injurious effect of cane-sugar. Thus, a solution containing 20.8 parts of nitrogen gave by the process, after removing chlorides, 12.6 and 11.5, but with chlorides not removed, 18.5. In some cases the author has observed that the reaction is not completed in the shaking-tube, but that bubbles of gas continue to be evolved when the liquid was transferred to the measuring-tube; the reason of this defective reaction was not discovered. The author draws the following conclusions:—That in the absence of organic matter, and with proper manipulation, the method is one of great accuracy, and is capable of determining extremely small quantities of nitrates and nitrites; the natural error of the process is a small one of deficiency; the presence of chlorides in moderate quantity is no hindrance; quantities of organic matter, small in relation to the nitrates present, have little or no effect on the results; larger quantities, especially of cane-sugar, may cause a considerable deficiency; this deficiency is reduced by the presence of chlorides, but is not entirely removed.

After a few remarks by Dr. GILBERT,

The PRESIDENT called on Dr. O. N. WITT to read a paper "On a New Class of Colouring Matters." This is the first part of a series on the simultaneous gradual oxidation of amido and methyl groups. If a mixture of meta-toluylen-diamin and dimethyl-para-phenylen-diamin be oxidised in aqueous solution, or if the formation of the latter of these bases from nitroso-dimethyl-aniline be combined with this oxidation process, by acting upon meta-tolulylen-diamin with nitroso-dimethyl-anilin, the reaction results in either case in the formation of a new compound of an intense blue colour, for which the author proposes the name of toluylen blue, $\text{C}_{15}\text{H}_{16}\text{N}_4\text{HCl} + \text{H}_2\text{O}$. It is the neutral salt of a new triatomic base, the acid salts being reddish brown. If treated with reducing agents it absorbs 2 atoms of hydrogen, forming a new colourless base, having the constitutional formula—

and the formula of the blue is—

This compound may be considered as the first representative of a new class of colouring matters, which have the group—

as a chromophor, and form, from their properties and constitution, a connecting link between the rosanilin and the azo series, the chromophor of the former being—

and of the latter—

One of the most remarkable properties of toluylen blue is its power of absorbing hydrogen from other amines, and being reduced to its leuko-compound, the amine undergoing condensation similar to that effected by oxidising agents and invariably resulting in the formation of new colours. Thus the blue, by acting on another molecule of itself produces toluylen pink, $\text{C}_{15}\text{H}_{16}\text{N}_4$, a crystallised compound forming two series of salts, one pink the other blue. By acting with toluylen blue on meta-tolulylen-diamin for twelve hours at 35° toluylen violet is obtained, $\text{C}_{14}\text{H}_{14}\text{N}_4$. This new compound dissolves sparingly in alcohol and ether with a pink colour, exhibiting a most brilliant fluorescence; it forms two series of salts, one violet the other green. The constitutional formula of toluylen pink is—

and of the violet—

The general conclusions which may be drawn are that under the above circumstances a gradual dehydrogenisation of the amido- and the methyl-groups takes place, the quantities of hydrogen removed from both sources being always the same; that in a great many cases the use of oxidising agents may be avoided by using the corresponding nitroso-compounds, or by utilising the tendency of some organic compounds for the absorption of hydrogen. The author promises further investigations in the same direction. Specimens of the above new and beautiful colouring-matters were exhibited by the author.

The Society then adjourned to May 15, when the following papers will be read:—"On Nitrification," Part II., by R. Warington; "On Alkaloids of the Veratrum,"

Part III., by Dr. Wright and Mr. Luff; "On Alkaloids of the Veratrums," Part IV., by Dr. Wright; "Alkaloids of the Aconites (Part IV.), and on Japanese Aconite Roots," by Dr. Wright and Mr. Luff; "On the Action of Hydrochloric Acid on Manganese Dioxide," by Spencer Pickering; "The Composition of Milk in Health and Disease," by A. Wynter Blyth; "Notes on the Effect of Alcohol on the Chemistry of Digestion," by W. H. Watson.

NOTICES OF BOOKS.

A Dictionary of Chemistry, and the Allied Branches of other Sciences. By HENRY WATTS, F.R.S., F.C.S., Editor of the *Journal of the Chemical Society*; assisted by Eminent Contributors. Third Supplement, Part I. Longmans and Co., 1879.

THIS is the third supplementary volume of "Watts's Dictionary" which has been issued since the completion of the body of that work, and brings the record of chemical discovery down to the end of the year 1877, including some of the more important discoveries which have appeared in 1878. The volume, which begins with "Absinthol" and ends with "Fustic," comprises only one-quarter of the letters of the alphabet; we do not see, therefore, how the other three-quarters can be compressed into the single volume mentioned in the Preface. It is true that the articles on those very fruitful bodies the benzo-compounds take up no less than one-fifth of the part, but, notwithstanding this, if the remainder of the alphabet is to be squeezed into a single volume, it will have to be a very bulky one, or else an injurious amount of compression will have to be exercised. The first important article we meet with is on Aniline Colours, which gives the best method of testing their tinctorial power by an accurately titrated solution of sodic hyposulphite. We also have accounts of the formation of aniline-black by the action of vanadic salts and by electrolysis; also of its composition and probable formula. The article also treats of aniline-green, grey, and red. Anthracen very naturally claims a large amount of attention, the newest views as to its molecular constitution being given at length. Its latest derivatives and its isomerides are then described, as well as its fluorescent properties. Under Anthraquinon we have a full account of the most recently discovered derivatives of that prolific body, and of the formation of artificial alizarin from pyrocatechin. Under this heading are also described quinizarin, purpurloxanthin, the anthroflavic acids, the anthroflavons, chrysazin, purpurin, anthrapurpurin, flavo-purpurin, oxy-chrysazin, and rubopin. Under Arsenic the continuation of Nilsson's classical researches on the compounds of that metal are described, more especially those on its sulphur salts. In the article Atmosphere we have the most recent determinations of the amount of carbon dioxide, ammonia, hydrogen peroxide, and dust in the air by various observers. A few pages further on we have an exhaustive article on barley, from Mr. R. Warington, the most recent results obtained by Messrs. Lawes and Gilbert being fully described. Under Beer we have full directions for the detection of foreign bitters in that beverage, from which we learn that brewers use nearly thirty different "hop-substitutes," more or less poisonous, from strychnine and brucine to gentian and wormwood. Benzacetic acid introduces us to the benzo-compounds, to which no less than 167 pages are devoted. It is strikingly indicative of the progress of research in this direction that in the original work the account of these compounds from their first discovery onwards only took up 40 pages, while in the first and second supplements we have 82 and 57 pages respectively given to these bodies. In these articles the vexed question of the determination of the relative posi-

tions of the substituted radicles in benzene-derivatives is fully discussed, the views of Körner, Graebe, and others being given. The constitution and structure of the various mono-, di-, tri-, and tetra-bromo-benzene, as well as of their nitro- and chloro-congeners, are also thoroughly investigated. This article likewise contains an account of the iodo-, bromo-, and chloro-derivatives of aniline, the amido-benzenes, and the azo-benzenes. A useful table is given of the abbreviated symbol, the physical properties and positions of the substituted radicles of more than 120 ortho-, meta-, and para-benzene derivatives. The next part of this article treats of benzene-sulphonic acid and its numerous derivatives, and gives a table of the physical properties of its principal ortho-, meta-, and para-salts. A number of other tables are also given of the chemical and physical properties of the derivatives of benzene-meta-disulphonic acid and of those of the brom-amido-benzene-disulphonic acid. Benzoic acid and its numerous derivatives are next treated of, the newest methods of making ortho-oxy-benzoic acid or salicylic acid being fully described. Directions are added for the purification, detection, and estimation of this now important compound. The next important articles are those on the inorganic and organic compounds of boron. Under Cæsium we have Godeffroy's method of separating cæsium, rubidium, and potassium by preparing their alums and separating them by fractional crystallisation according to the process originally devised by Redtenbacher. The Cerite group of metals also receives ample treatment, a large number of their principal salts being fully described. The article on Chemical Action is an important one from a philosophical point of view, the velocity of chemical action, the retardation of chemical reactions by indifferent substances, the decomposition of certain salts by water, the mutual replacement of halogen elements, and other similar questions being discussed at great length. Chloral and its compounds have 8 pages devoted to them, while cinchona barks, bases, and compounds take up 26 pages. Cinnamic and citric derivatives also receive their full share of attention. Thomas's researches on the gases enclosed in the coal of the South Wales basin are given nearly in full under Coal. Cumulative Resolution is a highly philosophical article from the pen of Dr. Mills. The other important articles are on Flame, by Professor Thorpe; Forest Trees, by Professor Warington; on the Diphenyl Derivatives, which have nearly 30 pages given to them; Dye Stuffs, Electricity, Electro-capillarity, Ethyl Derivatives, Fermentation, Fulminates, and Fulminurates.

For the second part, which we trust will shortly appear, we are promised contributions by Drs. Armstrong, Roscoe, Thorpe, Flight, and Professors G. C. Foster and R. Warington.

The Chemistry of Common Life. By the late JAMES F. W. JOHNSTON, Professor of Chemistry in the University of Durham, &c. A New Edition, revised and brought down to the present time, by ARTHUR HERBERT CHURCH, M.A. Oxon, &c. Blackwood and Sons, 1879.

JUST twenty years have elapsed since that versatile writer the late Mr. G. H. Lewes took up the pen which, so to speak, had fallen from Prof. Johnston's hand some two or three years before, and brought a second edition of a book which, amongst popular scientific works, had already taken its stand by the side of "Liebig's Letters on Chemistry." Prof. Johnston had performed his task so thoroughly that Mr. Lewes's utmost diligence had not been able to glean much after him, although seven years had passed between the appearance of the original and the revised editions. The book had three great merits—it was written in a popular and entertaining style, it was comprehensive in the choice of subjects, and, above all, it was thoroughly exact. It seems, therefore, strange that a couple of decades should have been allowed to pass

away between the publication of the second and third editions.

Mr. Church has executed his task as a pious duty, and has been most careful to respect the method, the style, and the matter of Prof. Johnston's original, only such corrections and alterations having been made as were rendered necessary by the recent advances made in scientific knowledge. Only very few additions have been made, one of them of notable value, in the form of a chapter on the Colours we Admire, which forms a fitting pendant to the well-known chapters on the Odours we Enjoy. A sketch is given of the origin and properties of hæmaglobin turacin, the cupreous pigment discovered by Mr. Church in the red colouring matter of the wing feathers of some eleven species of the Touraco, the black pigment found in black hair and feathers, chlorophyll, coelein, alizarin, and, lastly, of the coal-tar dyes.

In bringing out the third edition of this work Mr. Church possessed an advantage over the late Mr. Lewes, for he had the opportunity of consulting Prof. Johnston's private and corrected copy of the "Chemistry of Common Life," so that he was not only enabled to incorporate in his revisions some valuable matter gathered by the late author, but to learn the kind of additions which he contemplated.

Although appearing in one volume instead of two, as in the case of the first two editions, the present issue contains more matter, the type being smaller and closer and the pages larger.

OBITUARY.

WILLIAM GEORGE VALENTIN, F.C.S.

LAST week we stated that a committee had been formed for the purpose of presenting Mr. Valentin with a testimonial in recognition of his long services to chemical science. It is now our painful duty to announce that he died suddenly on the 1st instant from apoplexy. This well-known chemist was born at Neuenburg, in the Black Forest, on the 16th of May, 1829. He came to England in 1855, and in the early days of the College of Chemistry studied under Dr. Hofmann, who esteemed him greatly, and, recognising his ability, made him Senior Assistant in the Laboratory. He retained this position under Dr. Frankland, with whom he organised the new laboratories of the Science Schools, South Kensington. He was also Gas Examiner to the Great Western Gas Company, and Chemical Adviser to the Trinity House. We have in these pages frequently pointed to the merits of his various text-books of practical chemistry, and within the last few days he corrected the final proofs of a new work which will shortly be published. His success as a teacher and his skill as an analyst are so well known that they need not be alluded to further, and at present we can only take this, the earliest, opportunity of expressing the regret that will be so widely felt at his loss. Unfortunately, he leaves a widow and a family without provision, and the labours of the committee to which we referred last week will be continued for their benefit. The Hon. Treasurer is Mr. F. W. Bayley, Royal Mint, E., who will gladly acknowledge any contributions that may be sent to him.

New Reagent for Carbohc Acid.—One to two drops of the liquid should be placed in a porcelain capsule with the addition of 2 or 3 drops of a solution of molybdic acid in 10 parts of sulphuric acid. If carbohc acid is present there is produced immediately a light yellow or yellowish brown colour, which changes to a maroon, and finally to a purple. The solution should be very dilute.—*Polyt. Notisblatt.*

CORRESPONDENCE.

PRECIPITATION OF METALLIC COPPER BY POOR COPPER MATT.

To the Editor of the Chemical News.

SIR,—Having lately read the very interesting paper by Mr. Dixon, on the "Method of Extracting Gold, Silver, and other Metals from Pyrites," which appeared in the *CHEMICAL NEWS*, I should like to correct one statement made there in reference to the precipitation of metallic copper, from solution of its sulphate, by poor copper matt. In the above paper Mr. Dixon says (*CHEMICAL NEWS*, vol. xxxviii., p. 303) that:—"Whilst experimenting on the removal of copper from solution I found that this could be conveniently done by filtering the slightly acid solution by ground matt obtained from the same ore by simple melting. This method of separating copper from solution may be of advantage in treating poor copper ores or pyrites containing small quantities of copper:—The matt obtained by simply melting poor cupreous pyrites, with the addition of sufficient roasted ore to form a flux for the silica present, consists of sulphide of iron containing more or less sulphide of copper; and by filtering through a bed of this matt, the solution of sulphate of copper obtained by calcining and extracting a large portion of the ore, the copper is deposited, and the iron goes into solution. I expected to find that the whole of the iron could be thus removed from the matt which would be converted into sulphide of copper, but found that in all cases the action stopped short of this. The percentage of copper in the treated matt varied from 30 to 33 per cent, approximating, therefore, to copper pyrites, which contains 34.6 per cent of copper. From this residue refined copper could be made in three operations."

Now, before having read that paper, I had already been making experiments on the same subject to see if it were possible to raise the percentage of copper in poor matt by some simply wet process, in which the use of acids could be avoided, as by calcining poor cupreous pyrites in heaps, by which means large quantities of sulphates of copper and iron would be produced. I found by filtering a solution of sulphate of copper through a bed of matt containing from 13 to 16 per cent copper, smelted in cupola furnaces, that the percentage of copper was nearly doubled, but on examination I found that this was accounted for by the presence of a large quantity of metallic iron which had been reduced in the furnaces, and had been tapped out with the matt. This iron was disseminated through the mass in very minute globules, and was easily extracted from the ground matt by means of a magnet. To make sure that it was only owing to the presence of this metallic iron that precipitation of copper took place I took some samples of poor matt produced in reverberatory furnaces, and found that no precipitation of copper whatever took place, except in one instance, where 0.83 per cent of copper was thrown down by a sample of matt containing 22 per cent copper, and in this case a small quantity of metallic iron was detected by the magnet, which may possibly have been derived from pounding the sample, which was very hard, in a rather soft iron mortar. The following is the result obtained by treating various samples of poor matt containing metallic iron with a sulphate of copper solution.

A saturated solution of cupric sulphate, slightly acidified (as recommended by Mr. Dixon), was filtered through a layer of 1000 grains finely ground matt, placed in a funnel, the neck of which was plugged with asbestos, till no further precipitation of copper took place. The matt was then washed, dried, and the copper estimated.

	I.	II.
	Per cent.	Per cent.
Matt, after above treatment = Copper ..	26.50	25.63
" before " " = " ..	14.35	14.12
Copper thrown down from solution ..	12.15	11.51

No. I. was a mixture of samples from about 250 taps, and No. II. from above 1200 taps.

The analysis of the two samples of matt is as follows:—

	I.	II.
Copper	14'35	14'12
Iron	56'14	55'47
Sulphur	29'51	30'41
	100'00	100'00
or—		
Sulphides of copper and iron	89'06	88'69
Metallic iron	10'94	11'31
	100'00	100'00

It will be thus seen that the quantity of copper precipitated is directly proportional to the quantity of metallic iron contained in the matt, the theoretical amount of iron required to precipitate copper from solution being in the proportion of 1 part iron to 1'133 parts copper; the amount of copper precipitated in the above cases being in the proportion of:—

No. I.	Iron.	Copper.
No. II.	I to	1'110
	I to	1'017

This proportion is far higher than the results generally obtained by precipitating copper from solution by means of scrap iron, the quantity used in practice ranging from 2 to 4 times the amount required by theory.

The precipitation of copper by the matt was very rapid, owing to the very fine state of division of the metallic iron. This reduction of iron to the metallic state is one great drawback to the smelting of poor cupreous pyrites in cupola furnaces, as unless a very strong and hot blast is kept up (in order to run the ore down as rapidly as possible) the iron soon forms and sets below the tuyeres commencing at the back of the furnace and gradually extending till the tap holes are quite choked up with it; the furnace has then to be cooled down and the mass of iron cut out.

As the above results may be of interest to some of your readers, and may correct some erroneous impressions on this subject, I should feel obliged by your inserting this letter.—I am, &c.,

A. E. BARCLAY.

Bells Cove Copper Mines, Newfoundland,
April 17, 1879.

THE VITRIOL MANUFACTURE,

To the Editor of the Chemical News.

SIR,—My name occurring so many times in Dr. Hurter's letter (CHEM. NEWS, vol. xxxix., p. 170) calls for remark; but first I would mention that Dr. Hurter spells my name incorrectly in every instance.

At the conclusion of his letter he writes—"It is not, in my opinion, of any service to the manufacturer to put him off his guard, and prevent further search by such statements." Now I wish to point out that at the time of reading my three papers before the members of the Faraday Club, I distinctly stated that the instances E, F, and G (working with towers) were not satisfactory, and I urged the members of the Club to work in this direction. With regard to the oxidation of the arsenious acid by the nitrous anhydride, this reaction was repeatedly tried in the Laboratory without success; still, finding nitric oxide in the outlet, and also finding that the arsenious acid was oxidised to arsenic acid in running down the tower, I supposed that as the physical conditions were different the supposed reaction might take place in the tower. When I perceived I might have been mistaken, and that N_2O_4 might have been the oxidiser, and not N_2O_3 , I wrote the letter (CHEM. NEWS, vol. xxxvii., p. 195).

Dr. Hurter, in his letter already quoted, and also in a statement made to the Noxious Vapours Committee of

the Alkali Makers' Association, asserts that the exit gases contain sufficient oxygen to convert the N_2O_4 into N_2O_3 , and therefore that N_2O_4 is never to be found in exit gases.

It would be very interesting if those chemists who have observed N_2O_4 passing in company with oxygen would come forward and state what they have found.

I have a set of experiments going on which may tend to throw some light on the subject of the oxidation of the arsenic. I still maintain that N_2O_4 does go away in the exit gases when from 4 to 8 per cent of oxygen is present. This may be only under certain conditions of working, but still I have found it, and so have others.

I never considered that the samples from absorber exits E, F, and G (CHEM. NEWS, vol. xxxvii., p. 157) were satisfactory solutions of the question. E gives more nitre escaping than used; of F I gave no exit tests; and G I stated that the chambers were old, much air was drawn in at the last ones, and the amount of nitre unaccounted for was 20 per cent.

Dr. Hurter states that my figures prove that the chemical losses in the chambers are from 10 to 15 per cent. Now I stated distinctly that in samples A, B, C, and D the total unaccounted for was 5 to 9 per cent. This quantity might be decomposed in the chambers where steam is present, but I have no proof of it, neither do I know any one who has.

Dr. Hurter draws his conclusions on the exit escape of nitre from the averages of seven different works. I am convinced that as long as this is done we shall never arrive at the true cause of all the nitre losses. These losses must be studied in each individual works, and where the conditions always remain the same. One works may have an equal number of chambers of a similar size with another works, doing the same work, and with denitrators and absorbers equal; one may be using 1'8 per cent of nitre, and the other 3 per cent; and again, in the same works an even number of chambers may be divided into two sets, and yet one may always consume more nitre than the other, in order to prevent an escape of SO_2 .

The difficulties which surround this subject may be inferred from Mr. E. Jackson's letter (CHEM. NEWS, vol. xxxviii., p. 147), in which he states—"Thus during the past week the average quantity of nitre found in the exit gases does not exceed 4 lbs. per ton of stone, while about a month ago the quantity found during one week exceeded the quantity used for that week." Since then Mr. Jackson has informed me that during one whole period of six months he could account for all the nitre used, within a small percentage, without reference to any theory of reduction to nitrogen or nitrous oxide. Perhaps the following experiments may be of use to investigators:—

1. The acid was issuing from a Glover tower at 150° Tw. cold, and at a temperature of 290° F. containing 0'02 per cent of nitrogen compounds, calculated at N_2O_3 by the mercury method. A damper was now inserted in the iron pipe (leading the SO_2 gas into the tower) having in its centre a 4-inch circular opening, a direct (extra) way being opened for the gases to go direct into the chambers. The small quantity of SO_2 which now went up the tower effected no concentration, the acid was perfectly denitrated, the issuing acid was from 90° to 100° F., and no saving of nitre was effected.

2. The nitrous vapours were being boiled off in pots placed in a very cool part of the flue leading from the kilns to the chambers (working without towers). The consumption of nitre was 4'2 per cent upon 47 per cent of sulphur. The potting place was changed to a bright red-hot portion of the flue; this change caused no more nitre to be used, nor was the colour of the chambers or escape in any way affected. The potting place was again changed to where the active combustion was going on, and this spot was nearly at a white-heat: within a few hours from this change the chambers began to grow pale, hard potting was necessary, more nitre was used for some time—to try

and bring the colour of their chambers to their normal conditions—without success, and when the first and original potting place was resumed the nitre went down to its original amount.

3. It is thought by some that the last chambers reduce the N_2O_4 to NO_2 by means of the excess of water present (i. e., the low density of the acid). It was tried to work the last chambers stronger than usual, viz., 136°Tw. , to 140°Tw. ; the result was a greater use of nitre than before, even taking into consideration the amount absorbed by the acid. This experiment was going on for many months, and during the whole of the time the total acidity of the exit was more regular and lower than when the last chambers were worked weaker.

4. Tests of inlet and outlet of absorbing towers:—

a = Na_2CO_3 neutralised by S compounds, grains per cubic feet.

b = Na_2CO_3 neutralised by N compounds, grains per cubic feet.

c = oxygen per cent by volume.

		Inlet.	Outlet.
1.	a.	5'90	3'65
	b.	1'40	0'70
	c.	9'80	Colourless.
2.	a.	2'98	2'79
	b.	1'02	0'08
	c.	10'25	Colour pale straw.
3.	a.	2'55	2'36
	b.	1'79	0'11
	c.	11'25	Colour straw.
4.	a.	4'80	4'05
	b.	1'69	1'11
	c.	5'90	Colourless.
5.	a.	3'62	3'42
	b.	1'84	1'02
	c.	6'60	Colourless.
6.	a.	1'07	1'00
	b.	2'04	0'11
	c.	10'27	Colour straw.

Before leaving this subject I wish to point out that Dr. Hurter has applied the most refined methods to the ascertaining of the mechanical losses; he should therefore be able to give us them within 1 or 2 per cent.

I have heard it remarked that Lunge has stated that my process for the estimation of nitrous compounds in nitrous vitriol, by shaking up with mercury and measurement of the nitric oxide, is liable to an error of as much as 10 per cent, on account of my not taking the temperature and pressure into consideration. I have heard that this has been abstracted into the *Journal of the Chemical Society*, though I have not seen it,—therefore it is necessary for me to quote from my paper (CHEM. NEWS, vol. xxxvii., p. 45):—"For technical purposes this volume will be found accurate enough, but in cases where extreme accuracy is required the tube must be left to itself for several hours, the temperature and pressure noted, and the necessary corrections made."—I am, &c.,

GEORGE E. DAVIS.

Heaton Chapel, Stockport,
April 28, 1879.

Determination of Nitric Acid Contained in Commercial Lime-Juice.—F. Dotto-Scribani.—The author takes 100 c.c., boils the liquid, and neutralises exactly with baryta water. Citrate of barium is formed and precipitated, whilst barium nitrate remains in solution. The liquid is let cool, the citrate is separated from the nitrate by filtration, and the latter salt is decomposed with sulphuric acid. The barium sulphate obtained is filtered, washed, &c., and weighed with the usual precautions, and on multiplying its weight, less the ash of the filter, by 0'4635 the quantity of nitric acid present in 100 c.c. of the juice is obtained.—*Gazzetta Chimica Italiana*.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale.

No. 62, February, 1879.

Report Presented by M. le Comte du Moncel on Behalf of the Committee of Economical Arts on M. E. Reynier's Electric Light Regulator.—The committee decide that M. Reynier has solved the problem in question. His arrangement has been successfully tried at the station of the Northern railway and in M. Breguet's work-shop, where it has acted for some hours with regularity under the influence of the current of a small Gramme machine. The arrangement is figured on the accompanying plate.

Report Presented by M. Aimé Girard on M. Kuhlmann's (junior) Methods for Recognising the Composition and Measuring the Volume of the Gases and Acid Vapours given off by the Chimneys of Chemical Works.—By means of this arrangement a manufacturer can at any hour inform himself concerning the nature of the gases traversing his chimney. To establish the composition of the chimney-gases and to detect, e.g., the presence of hydrochloric acid therein, M. Kuhlmann introduces into the shaft a glass tube, which communicates with a series of test-tubes, at the end of which is a cistern of water, which acts as a respirator. The flow of water compels the gas to traverse the series of test-tubes, the first of which contains caustic soda coloured with litmus. Then follow solutions of barium chloride and silver nitrate. The dimensions of the cistern are such that five or six hours are required for the total efflux of the water which it contains, and the strength of the alkaline liquid coloured blue is such that in the regular course of work five or six hours are required to turn them red. An earlier colouration gives immediate warning. M. Kuhlmann's method of measuring the total volume of gases escaping is as follows:—When he wishes to know the speed of the gases he introduces at the bottom of the chimney a certain volume of a strong-coloured gas, such as hyponitric acid, which accompanies the colourless gases up the chimney and presents itself along with them at the top. Knowing, then, the volume of the chimney and the mean temperature it is possible to calculate from the time which has elapsed the quantity of gas emitted.

Bulletin de la Société Chimique de Paris,

No. 6, March 20, 1879.

Action of Mono-chlor-acetic Acid upon Sulphocyanic Acid and its Salts.—M. Nencki.—On heating a mixture of 1 mol. chlor-acetic acid dissolved in double its weight of water with 3 mols. ammoniac sulphocyanate, the liquid obtained deposits crystals of a new compound, rhodanic acid, $\text{C}_3\text{H}_2\text{NS}_2\text{O}$, which crystallises in tables and six-sided prisms of a fine yellow, scarcely soluble in cold water, but readily in alcohol, ether, and alkalis. It melts about 168° to 170° with partial decomposition, yielding a brown-red liquid. Under the influence of feeble oxidising agents it produces colouring matters. A red and a violet matter have thus been obtained which in acid solutions dye silk and wool, and in alkaline solutions produce a blue shade upon cotton.—*Journal f. Praktische Chemie*, xvi., 1.

Action of Cyanogen upon Albumen.—O. Loew.—By treating albumen with cyanogen gas the author obtains three new compounds, cyalbidin, oxamoidin, and a third body not named.—*Journ. f. Prakt. Chemie*, xvi., 60.

Certain Derivatives of Campho-thymol.—E. Paterno and F. Canzoneri.—An account of nitroso-campho-thymol and amidico-campho-thymol.

Constitution of the Cymen of Cuminic Alcohol and of its Thymols.—E. Paterno and P. Spica.—Not suitable for abstraction.

Propyl-benzoic Acid.—E. Paterno.—A claim of priority as against H. Koerner.

Benzylated Cymen.—Dr. Girolamo Mazzara.—The author finds this compound to consist of—Carbon, 91.00; hydrogen, 9.10; and gives it the formula—

Process for Discovering the Effective Quantity of Tartaric Acid Contained in Dregs of Wine.—Prof. Francesco Dotto-Scribani.—This process serves for determining the effective quantity of tartaric acid not merely in unadulterated but even in the dregs of plastered wines. 10 grms. of the dregs are reduced to a very fine powder and dried in the water-bath, and then moistened and made into a paste with pure hydrochloric acid in a porcelain capsule, and allowed to stand for twenty-four hours. The mass is then lixiviated with boiling distilled water, the liquid is filtered, and this treatment is repeated with the residue upon the filter till the liquid passing through no longer reddens litmus paper. The filtrate is then boiled in a porcelain capsule, and whilst it is continually stirred with a glass spoon milk of lime obtained by levigation and passed through a strainer is added little by little until the liquid begins to turn red litmus paper blue. The capsule is then allowed to cool and the contents thrown upon a double filter, which has been previously well washed, and the precipitate is then washed, until on acidulating the washings with nitric acid and testing with nitrate of silver no turbidity is observed. The precipitate with the double filter is then dried in the water-bath and weighed, having care first to detach the outer from the inner filter, and to place the former in the weight-scale, and from its weight is deduced the effective quantity of tartaric acid, since 100 parts of calcium tartrate contain 57.69 parts of tartaric acid. This process is founded on the following principles:—The acid tartrate of potassium and the tartrate of calcium are less soluble in boiling water than in such water acidulated with hydrochloric acid, with which the two salts produce chlorides of potassium and calcium, while tartaric acid is set free. The colouring matter of the dregs is insoluble in hydrochloric acid. Milk of lime has no action upon the chlorides, but transforms the tartaric acid into calcium tartrate.

MISCELLANEOUS.

Chemistry in Australia.—Mr. R. W. E. MacIvor A.I.C., &c., late Senior Assistant to Professor Dittmar, at Anderson's College, Glasgow, has for the last three years been engaged in lecturing to the farmers throughout Victoria on Agricultural Chemistry, and has succeeded in impressing upon them the importance of the subject, for many come 40 and even 50 miles to listen to him. In referring to Mr. MacIvor's discourses, the *Lancefield Chronicle* for March 20 says:—"The amount of good derived from these scientific dissertations has been incalculable to the agriculturist, and the knowledge imparted has increased the prosperity of the country." It is but fair to mention that these lectures are given free of charge to the agricultural community, the expense attending their delivery being borne by the Hon. William J. Clarke, M.L.C., President of the forthcoming Melbourne International Exhibition.

Detection of Arsenic.—The matter containing the arsenious or arsenic acid is introduced into a Marsh's apparatus, and mixed with a concentrated solution of caustic potassa and a little aluminium foil. Arseniuretted hydrogen is disengaged on applying heat. Antimoniu-retted hydrogen is not formed.—*Moniteur Scientifique*.

Technological Examinations.—The Council of the Society of Arts, having received an application from the City and Guilds of London Institute for the Advancement of Technical Education, offering to take charge of the Technological Examinations established by this Society in 1873, and carried on up to the present time, have resolved to transfer these examinations to the charge of the Institute. The Council have also ascertained that the Science and Art Department will assist the City Institute in conducting the examinations, in the same way as it has hitherto assisted the Society of Arts. The Technological Examinations for the present year will, therefore, be carried on under the direction of the Institute, and all communications on the subject should be addressed to the Hon. Secretaries, City and Guilds of London Institute, Mercers' Hall, E.C.

Science-Teaching in Public Schools.—A correspondent suggests that a careful and trustworthy account of the teaching of science in schools would be of great value, by laying before the public facts and not mere theories. As an instance of such theories he mentions the assumption of no less eminent a man than Sir J. Lubbock that boys would be anxious or willing to study science in play hours. He points out from among 500 boys few care to hear even such a lecturer as Prof. Tyndall, and none would go a second time except other work was remitted in compensation. Our friend informs us that at Harrow and at some other public schools any boy at the desire of his parents can give several hours weekly to practical work in chemistry or physics. "The parents of boys in general do not care about their learning practically, and it is from them, rather than from the masters, that the difficulty arises." May we suggest that such indifference or disinclination on the part of parents springs from the fact that successful practical work in science counts for little in determining a boy's standing in the schools?

MEETINGS FOR THE WEEK.

- MONDAY, 12th.—Royal Geographical, 8.30.
Society of Arts, 8. "Recent Advances in Telegraphy," by W. H. Preece. (Cantor Lectures.)
- TUESDAY, 13th.—Civil Engineers, 8.
Royal Institution, 3. "The Intellectual Movement of Germany from the Middle of the Last to the Middle of the Present Century," Prof. Hillebrand.
Photographic, 8.
Anthropological, 8.
- WEDNESDAY, 14th.—Society of Arts, 8. "The Automatic Hydraulic Brake," Mr. E. D. Barker.
Geological, 8.
Microscopical, 8.
- THURSDAY, 15th.—Royal, 8.30.
Royal Institution, 3. "Dissociation," by Prof. Dewar.
Royal Society Club, 6.30.
Society of Arts, 8. "The History of Alizarin and Allied Colouring Matters, and their Production from Coal-Tar," by W. H. Perkin, F.R.S.
Chemical, 8. "On Nitric Acid, Part II.," Robert Warington. "On Alkaloids of the Veratrum, Part III.," Dr. Wright and Mr. Luff. "On Alkaloids of the Veratrum, Part IV.," Dr. Wright. "On Alkaloids of the Aconite, Part IV.," and on Japanese Aconite Roots, Dr. Wright and Mr. Luff. "Action of Hydrochloric Acid on Manganese Dioxide," S. Pickering. "Composition of Milk in Health and Disease," A. W. Elyth. "Notes on the Effect of Alcohol on the Chemistry of Indigestion," W. H. Watson.
- FRIDAY, 16th.—Royal Institution, 9. "Etude Optique de l'Elasticité," Prof. Cornu.
- SATURDAY, 17th.—Royal Institution, 3. "Architecture," by Mr. H. H. Statham.

Just published, with Illustrations, fcap. 8vo, cloth, 4s.

A MANUAL OF ORGANIC CHEMISTRY,
Practical and Theoretical, for Colleges and Schools, Medical and Civil Service Examinations, and for Elementary, Advanced, and Honours Students at the Classes of the Science and Art Department, South Kensington. By **HUGH CLEMENTS.**

London: BLACKIE and SON, 49 and 50, Old Bailey;
Glasgow, Edinburgh, and Dublin.

Now Ready, crown 8vo., 600 pp., with 470 Wood Engravings,
12s. 6d., cloth.

THE STUDENT'S TEXT-BOOK OF ELECTRICITY. By **HENRY M. NOAD, Ph.D., F.R.S.**, author of "A Manual of Electricity," &c. A new edition, carefully revised, with an introduction and additional chapters by **W. H. PREECE, M.I.C.E.**, Vice-President of the Society of Telegraph Engineers, &c.

Extract from Introduction by W. H. Preece, Esq.

"The original plan of this book has been carefully adhered to so as to make it a reflex of the existing state of Electrical Science adapted for Students. . . . Discovery seems to have progressed with marvellous strides; nevertheless it has now apparently ceased, and practical applications have commenced their career; and it is to give a faithful account of these that this fresh edition of Dr. Noad's valuable Text-Book is launched forth."

London: CROSBY LOCKWOOD & Co., 7, Stationers' Hall Court.

JUST PUBLISHED, 4th EDITION.
10s. 6d. cloth, Demy 8vo., pp. 420,

THE

PATENTEE'S' MANUAL.

A Treatise on the Law and Practice of Letters Patent, especially intended for the use of Patentees and Inventors.

BY

JAMES JOHNSON, ESQ.,

Of the Middle Temple, Barrister-at-Law, and

J. HENRY JOHNSON,

Solicitor and Patent Agent, Assoc. Inst. C.E. 47, Lincoln's Inn Fields, W.C., and Glasgow.

This Edition, much enlarged, gives a practical reference to every reported case of importance, and contains all the information on the law and practice of Patents Inventors and Patentees can require.

The Appendix contains the Statutes and Rules, and a summary of the Laws of all Foreign States and British Colonies.

London: LONGMANS and CO.

IMPORTANT TO SULPHURIC ACID MANUFACTURERS.

NORRINGTON'S PATENT.

In the ordinary method of Manufacture, at the time of charging the Kilns, a considerable escape of gases takes place. This is attended with proportionate loss of Sulphur, and with much inconvenience to the workmen, as well as annoyance to the vicinity of the Works. This may be entirely avoided by the adoption of C. Norrington's patented invention, which can be applied at moderate cost to existing Plant, as well as in the erection of new Works. It may be seen in full operation on extensive Plant at Messrs. C. Norrington and Co.'s Chemical and Manure Works, Cattadown, Plymouth, where the fullest information may be obtained, with terms for license.

MINERALOGY AND GEOLOGY.

NEW LIST of Collections of Minerals, Fossils, and Rocks, with prices. New List of Minerals for Chemical Purposes, Manufactures, and Research. New List of Varieties of Rocks. New List of Prices and Sizes of Cabinets for Natural History and other purposes. New Catalogue of Secondhand and New Books on Geology and Kindred Sciences. New Supplementary List of Books. New List of Sections of Rocks and Minerals for the Microscope. New List of Prices and Patterns for Geological Hammers. New List of Blowpipe Cabinets, Apparatus, and Materials. Also Implements and Appliances for practical work in Geology and Mineralogy.

Post free on application to **JAMES R. GREGORY**, Geologists and Mineralogists' Repository, 88, Charlotte Street, Fitzroy Square London.

PATENTS.—Mr. Vaughan, F.C.S., British, Foreign, and Colonial PATENT AGENT. Special attention given to Inventions relating to Chemistry, Mining, and Metallurgy "Guide to Inventors" Free by Post.—Offices, 67, Chancery Lane London, W.C., and 8, Houndgate Darlington.

Vol. XXXIX. No. 1016.

RECENT CONTRIBUTIONS TO THE HISTORY
OF DETONATING AGENTS.*

By Professor ABEL, C.B. F.R.S.

(Concluded from p. 200.)

In comparing the effects of these nitro-glycerin preparations with each other and with compressed gun-cotton and preparations of it, by detonating equal quantities quite unconfined upon iron plates, the results appear to establish great superiority, in point of violence of action, or destructive effect, of the more rigid explosive agents (the gun-cotton preparations). Thus, employing iron plates 1 inch thick (supported upon an anvil with a central cavity), and 4 ozs. of each material unconfined, the charges being all about the same diameter, exploded by detonators of equal strength, and simply resting upon the upper surface of the plate, compressed gun-cotton produced a considerable indentation of the upper surface of the plate, and long cracks in the lower surface; a species of nitrated gun-cotton, called tonite, produced a much shallower indentation, though still a very marked one, but did not crack the lower surface. Dynamite produced only a very slight impression upon the plate, and none could be detected by the eye on the plate upon which the blasting gelatin was exploded. The difficulties, brought out by past experience, which attend the contrivance of really comparative tests of the explosive power of such substances as those under discussion, is well exemplified by the foregoing results, which were influenced to the maximum extent by the physical characters of the several substances when applied, as they were upon these iron plates, in a perfectly unconfined condition, so that the particles were free to yield to the force of the initiative detonation in proportion to their mobility. But, for this very reason, these experiments afford excellent illustration of the extent to which the development of detonation and the sharpness of its transmission through the mass is influenced not only by the inherent sensitiveness of the substance to detonation (or by its chemical instability) but also by the degree of proneness of their particles to yield mechanically to the force of a blow as applied by an initiative detonation. Thus, although in comparing two substances of similar physical characters, compressed gun-cotton and compressed nitrated gun-cotton or tonite, the superiority of the pure compound over the mixture, in point of sharpness and violence of action, is well illustrated, a comparison of the result furnished by the weakest of the four explosive agents tried, viz. tonite, with that of the substance which should be superior to all the others in explosive force (*i.e.* the blasting gelatin) demonstrates the important influence which the comparatively great rigidity of the mass in the one case exerts in favouring the completeness and sharpness of its detonation in open air, and the great disadvantage under which the other explosive is applied, arising out of the plastic and therefore readily yielding nature of the material. But if, by exposure to a moderate degree of cold, this plastic nitro-glycerin preparation is made to freeze (for it partakes of the property of the liquid itself of freezing at a temperature above the freezing-point of water, and becomes thereby converted into at least as rigid a substance as the two descriptions of gun-cotton) its detonation upon an iron plate produces an indentation, as well as a destructive effect upon the lower surface of the plate, very decidedly greater than those furnished by

the corresponding amount of pure compressed gun-cotton. Similarly, the effect produced by the detonation of dynamite upon a plate of the kind used, is but little inferior to that of gun-cotton, and decidedly greater than that of tonite, if it is employed in the frozen condition.

A series of experiments has been made with cylinders of lead having a central perforation 1.3 inches in diameter extending to a depth of 7 inches and leaving solid metal beneath of a thickness ranging from 3.5 to 5.5 inches, according to the size of the cylinders used. These furnished results of considerable interest as illustrating the action of these several detonating agents. Charges of 1.25 ozs. of each explosive substance were used throughout the experiments, and were placed at the bottom of the holes. By the detonation of the charges the cylindrical holes in the lead were enlarged into cavities of a pear shape (and sometimes approaching the spherical form), of various diameters; in some instances the metal was besides partially torn open in a line from the bottom of the charge-hole to the circumference of the lower face of the cylinder; and in the case of some of the gun-cotton charges, the fissure in the metal in this direction was complete, the base of the block being separated from the remainder, in the form of a cone. In the first place the portions of the holes above the charges were simply left open; in the subsequent experiments they were filled up to a level with the upper surface, with dry, fine, loose sand, or with water. The dimensions of the cylinders were increased in successive experiments until, in the case of every one of the explosives used, the mass of metal was sufficiently great to resist actual fracture at the base of the cylinder. Under the conditions of these experiments, more or less considerable resistance being opposed to the mechanical dispersion of the plastic explosive substances, their detonation was greatly facilitated, though even then the holes in the lead blocks being left open to the air, some amount of the blasting gelatin evidently escaped detonation; the widening of the upper part of the charge-hole in experiments of this nature made with the gelatin indicated that detonation was transmitted to small portions dispersed in the first instance and in the act of escaping from the block. In all the experiments, whether the holes were left open or filled with sand or water, the effect produced upon the base of the block by the detonation of compressed gun-cotton was considerably more violent than with the other explosive agents, indicating a sharpness of action which was only shared by the blasting gelatin when used in a frozen state in one of these experiments. The dimensions of the cavities produced by the gelatin were, at the largest part, considerably greater than those produced by the dynamite and nitrated gun-cotton (tonite), and slightly greater than those of the gun-cotton charges; but in the latter, the fracture of the base of the cylinder gave rise in most of the experiments to an escape of force, so that in these cases the effects of the detonation could not be well compared by measurements of the cavities. When the gelatin was converted by freezing into a rigid mass its superiority in explosive force even over compressed gun-cotton was well illustrated; the base of the lead block was all but blown out, the cavity produced was considerably the largest, and the suddenness and violence with which motion was imparted to the water tamping caused the top of the block also to be blown off in the form of a cone. An excellent illustration was obtained by comparing this result with those furnished by the gelatin in its normal plastic state of the influence exercised by the physical condition of an explosive substance upon the rapidity and completeness with which detonation is transmitted through its mass.

The difficulties attending the application of blasting gelatin, in some directions in which explosive agents are applied, on account of the uncertainty attending the development of its explosive force, even with the use of a comparatively powerful detonator, unless it be very strongly confined, has led to attempts to reduce its non-sensitive-

* Abstract of a Paper read before the Royal Institution of Great Britain, Friday, March 21, 1899.

ness to detonation by mixing it with materials intended to operate either by virtue of their comparatively great sensitiveness, or of their property, as solids, of reducing the very yielding character of the substance, or in both ways.

Some of these attempts have been attended with considerable success. Thus the incorporation of about 10 per cent of the most explosive form of gun-cotton or trinitro-cellulose, in a very finely divided state, with the gelatin, renders it so much more sensitive that it can be detonated with certainty in the open air by means of the strongest detonating cap now used for exploding dynamite. This effect appears to be less due to the comparative sensitiveness of gun-cotton to detonation than to the modification effected in the consistency of the material, which, though still plastic, offers decidedly greater resistance to a blow than the original gummy substance. The particles of hollow fibre of the gun-cotton appear also to have the effect of absorbing small quantities of nitro-glycerin which are less perfectly united with the soluble gun-cotton than the remainder, and which, existing as they do in somewhat variable proportions in the gelatin, have occasionally an objectionable tendency to exudation, if the incorporation of the ingredients has been less perfect than usual. The substance, when modified as described, has no longer that great adhesiveness which is exhibited by it in the original state, and which renders it less easy to manipulate.

Lastly, its explosive force appears to be in no way diminished by this modification of its composition, on the contrary, its superiority in this respect to compressed gun-cotton becomes more manifest, as demonstrated by some of the experiments with lead blocks, while its action partakes of that sharpness peculiar to the detonation of the rigid gun-cotton, as indicated by the fissure of that part of the metal situated beneath the charge. Finely divided cotton fibre has a similar effect to trinitro-cellulose in modifying the physical character and increasing the sensitiveness to detonation of the blasting gelatin, but its explosive force is, of course, proportionately reduced with its dilution with an inert substance.

Nobel has made the interesting observation that an addition to the blasting gelatin of small proportions of certain substances rich in carbon and hydrogen, which are soluble in nitro-glycerin, such as benzol and nitro-benzol, increases to a remarkable extent the non-sensitiveness to detonation of the original material; and this observation has led to experiments being conducted by engineer officers in Austria, with a view of endeavouring to convert the blasting gelatin into a material which should compete, as regards some special advantages in point of safety, with wet gun-cotton in its application to military and naval purposes, and especially as regards non-liability to detonation or explosion by the impact of rifle bullets. If boxes containing dry compressed gun-cotton are fired into from small arms even at a short range, the gun-cotton is generally inflamed, but has never been known to explode; the sharpness of the blow essential to the latter result, which the bullet might otherwise give, being diminished by its penetration through the side of the box before reaching the explosive. It is scarcely necessary to state that wet gun-cotton, containing even as little as 15 per cent of water, is never inflamed under these conditions. On the other hand, dynamite is invariably detonated when struck by a bullet on passing through the side of the box, and blasting gelatin, though so much less sensitive than dynamite, behaves in the same way in its ordinary as well as in the frozen condition. The Austrian experiments indicated that the gelatin when intimately mixed with only 1 per cent of camphor, generally, though not invariably, escaped explosion by the impact of a bullet, but that when the proportion of camphor amounted to 4 per cent the material was neither exploded nor inflamed, though, in the frozen state, it was still liable to occasional explosion. These results were considered indicative of a degree of safety in regard

to service exigences, approaching that of wet compressed gun-cotton. The camphoretted gelatin still labours, however, under the disadvantage of being readily inflammable, and of burning fiercely, and consequently of giving rise, like dynamite and dry gun-cotton, to violent explosion or detonation, if burned in considerable bulk; a result which was explained by the lecturer in his discourse delivered at the Royal Institution in 1872. Moreover, the camphoretted blasting gelatin is so difficult of detonation by the means ordinarily applied, that a large initiative charge of a very violent detonating mixture consisting of pure specially prepared trinitro-cellulose and nitro-glycerin is prescribed by the Austrian experimenters as being indispensable to its proper detonation.

The action of camphor and of other substances rich in carbon and hydrogen in reducing greatly the sensitiveness to detonation of the preparation of soluble gun-cotton and nitro-glycerin, is not to be traced to any physical modification of that material produced by the addition of such substances, and no satisfactory theory can at present be advanced to account for it on chemical grounds.

The camphoretted gelatin, like Nobel's original gelatin itself, may be kept immersed in water for a considerable time without any important change; the surface of the mass thus immersed becomes white and opaque, apparently in consequence of some small absorption of water, but no nitro-glycerin is separated, and on re-exposure to the air the material gradually assumes once more its original aspect. It has consequently been proposed to render the storage of blasting gelatin comparatively safe by keeping it immersed in water till required for use, but the test of time is still needed to establish the unalterableness of the material under this condition.

There can be little question that this interesting nitro-glycerin preparation, either in its most simple form or modified in various ways by the addition of other ingredients, promises, by virtue of its great peculiarities as a detonating agent, to present means for importantly extending the application of nitro-glycerin to industrial purposes; and it is not improbable that through its agency this most violent of all explosive agents at present producible upon a large scale may also come to acquire special value for important war purposes.

It has been pointed out that the complete solidification by freezing of plastic preparations containing nitro-glycerin, such as dynamite and the blasting gelatin, has the effect of facilitating the transmission of detonation throughout the mass, and of thus developing or increasing the violence of their action, under certain conditions of their applications, *i.e.*, when they are either freely exposed to air or not very closely or rigidly confined. But while, under circumstances favourable to the detonation of these substances, when in the frozen state, their full explosive force is thus much more readily applied than when they are in their normal (thawed) condition, the frozen substances are less sensitive to detonation by a blow or an initiative detonation. On the other hand, if subjected to the rapid application of great heat (as, for example, by the burning of portions of a mass of the explosive substance itself), a detonation is much more readily brought about with the frozen material than if it be in its normal condition. Thus a package containing 50 lbs. of cartridges of plastic dynamite when surrounded by fire burned away without any indication of explosive action; on submitting 10 lbs. of frozen dynamite to the same treatment that quantity also burned without explosion, though at one time the combustion was so fierce as to indicate an approach to explosive action; but when the experiment was repeated on the same occasion with 15 lbs. frozen dynamite a very violent detonation took place after the material had been burning for a short time, a deep crater being produced in the ground beneath.

The following is offered as the most probable explanation of this result. When a mass of dynamite, as in these cartridges, is exposed to sufficient cold to cause the nitro-glycerin to freeze, it does not become uniformly

hardened throughout, partly because of slight variations in the proportion of nitro-glycerin in different portions of the mixture composing the cartridge, and partly because unless the exposure to cold be very prolonged the external portions of the cartridges will be frozen harder or more thoroughly than the interior. It may thus arise that portions of only partially frozen or still unfrozen dynamite may be more or less completely enclosed in hard crusts, or strong envelopes, of perfectly frozen and comparatively very cold dynamite. On exposure of such cartridges to a fierce heat very rapidly applied, as would result from the burning of a considerable quantity of the material, some portion of one or other of the cartridges would be likely to be much more readily raised to the igniting or exploding point than the remaining more perfectly frozen part in which it is partly or completely imbedded. If the ignition of this portion be brought about (which it will be with a rapidity proportionate to the intensity of heat to which the cartridge is exposed), the envelope of hard frozen dynamite by which it is still more or less completely surrounded and strongly confined, will operate like the metal envelope of a detonator, in developing the initial pressure essential for the sudden raising of the more readily inflammable portion of the dynamite to the temperature necessary for the sudden transformation of the nitro-glycerin into gas, and will thus bring about the detonation of a portion of the cartridge, which will act as the initiative detonator to the remainder of the dynamite. On igniting separately, at one of their extremities, some dynamite cartridges which had been buried in snow for a considerable period, the lecturer has observed that, as the frozen material gradually burned away, very slight but sharp explosions (like the snapping of a small percussion cap on a gun nipple) occurred from time to time, portions of the frozen dynamite being scattered with some violence. He did not succeed in obtaining actual detonation by thus burning frozen cartridges surrounded by others in a similar condition, but he has been informed by Mr. McRoberts, of the Ardeer Dynamite Works, that he has more than once detonated a small heap of hard-frozen cartridges, weighing altogether 1 lb., by igniting one cartridge which was surrounded by the remainder. These facts appear to substantiate the correctness of the foregoing explanation. They point to the danger of assuming that, because dynamite in the frozen state is less sensitive to the effects of a blow or initiative detonation than the thawed material, it may therefore be submitted without special care to the action of heat, for the purpose of thawing it. Instances of the detonation, with disastrous results, of even single cartridges of frozen dynamite, through the incautious application of considerable heat (as, for example, by placing them in an oven, or close to a fire), have been, and are still, of not unfrequent occurrence, even though Mr. Nobel has insisted upon the application of heat through the agency only of warm water, as the sole reliable method of safely thawing dynamite cartridges.

While the sensitiveness to detonation of air-dry gun-cotton remains unaffected by great reduction in temperature of the mass, and while in this respect it presents advantages over nitro-glycerin preparations, wet gun-cotton becomes very decidedly more susceptible to detonation when frozen. Thus the detonation of gun-cotton containing an addition of from 10 to 12 per cent of water is somewhat uncertain with the employment of 100 grs. of strongly-confined fulminate, and 200 grs. are required for the detonation of the substance when containing 15 to 17 per cent of water; but the latter in a frozen state can be detonated by means of 30 grs. of fulminate, and 15 grs. are just upon the margin of the amount requisite for detonating with certainty frozen gun-cotton containing 10 to 12 per cent of water. The deadening effect of solid water upon the sensitiveness of gun-cotton to detonation is, in fact, intermediate between those of a liquid and of inert solid substances.

The effects produced and products formed by the explo-

sion of gun-cotton in perfectly closed spaces, both in the loose and the compressed form, and by its detonation in the dry and the wet state, have been made the subject of study by Captain Noble and Mr. Abel, the method of research pursued being the same as that followed in their published researches on fired gunpowder; results of considerable interest in regard to the heat of explosion, the pressures developed, and the products of explosion of dry and wet gun-cotton have been obtained, which are about to be communicated to the Royal Society.

It may briefly be stated that the temperature of explosion of gun-cotton is more than double that of gunpowder (being about 4400° C.); that the tension of the products of explosion, assuming the material to fill entirely the space in which it is fired, is considerably more than double that of the powder-products under the same conditions; that the products obtained by the explosion of dry gun-cotton are comparatively simple and very uniform under different conditions as regards pressure; that the products of *detonation* of dry gun-cotton do not differ materially from those of its explosion in a confined space, but that those furnished by the detonation of *wet* gun-cotton present some interesting points of difference. Messrs. Noble and Abel are extending their investigations to the nitro-glycerin preparations.

The great advance which has been made within the last twelve years in our knowledge of the conditions which determine the character of the metamorphosis that explosive substances undergo, and which develop or control the violence of their action, finds its parallel in the progress which has been made in the production, perfection, and application of the two most prominent of modern explosive agents, nitro-glycerin and gun-cotton. Discovered at nearly the same time, less than forty years ago, the one speedily attained great prominence on account of the apparent ease with which it could be prepared and put to practical use; a prominence short-lived, however, because the first, and somewhat rash, attempts to utilise it preceded the acquisition of sound and sufficient knowledge of its nature and properties. Even many years afterwards, when the difficulties attending its employment appeared to have been surmounted, the confidence of its most indefatigable partisans and staunchest friends received a rude shock, from which it needed the support of much faith and some fortitude to recover.

Meanwhile, the other substance, which now shares with it the honours of important victories won over gunpowder continued to be generally regarded as a dangerous chemical curiosity, even for some time after its present position as one of the most important industrial products and useful explosive agents was being gradually but firmly secured for it, step by step, by the talent and untiring energy of a single individual.

Almost from the day of its discovery, the fortunes of gun-cotton continued to fluctuate, and much adversity marked its career, until at last its properties became well understood, and its position as a most formidable explosive agent, applicable on a large scale, with ease, great simplicity, and with a degree of safety far greater than that as yet possessed by any other substance of this class, has now become thoroughly established. Since the lecturer last discoursed on the properties of gun-cotton, seven years ago, this material has attained a firm footing as one of the most formidable agents of defence and offence. For all military engineering operations, and for employment in submarine mines and torpedoes, compressed gun-cotton, stored and used in the wet condition has become the accepted explosive agent in Great Britain; within the last five years upwards of 550 tons have been manufactured for this purpose, and are distributed over our chief naval stations at home and abroad. Germany some years since copied our system of manufacture and use of gun-cotton; France has provided itself with a large supply for the same purposes; and Austria, where the acquisition of bitter experience of the uncer-

tainty of gun-cotton in the earlier stages of history, naturally gave rise to a persistent scepticism regarding its presenting trustworthiness, appears now also about to adopt wet gun-cotton for military and naval uses.

But while the usefulness and great value of compressed gun-cotton in these important directions has been established, its technical application has made but slow progress as compared with that of the simple nitro-glycerin preparation known as dynamite, which, in point of cost of production and convenience for general blasting purposes, can claim superiority over compressed gun-cotton. Already, in 1867, a number of dynamite factories, working under Nobel's supervision, existed in different countries; in that year the total quantity manufactured amounted to 11 tons; in another year the produce had risen to 78 tons; in 1872 it had attained to 1350 tons. Two years afterwards the total production of dynamite was nearly trebled, and in 1878 it amounted to 6140 tons.

There are as many as fifteen factories in different parts of the world (including a very extensive one in Scotland) working under the supervision of Mr. Nobel, the originator of the nitro-glycerin industry, and some six or seven other establishments exist where dynamite or preparations of very similar character are also manufactured.

How far the rate of production of dynamite will be affected by the further development of the value of Nobel's new preparation, the blasting gelatin, it is difficult to foresee, but there appears great prospect of an important future for this very peculiar and interesting detonating agent.

It is hoped that the subjects dealt with in this discourse afford interesting illustration of the intimate connection of scientific research with important practical achievements.—F. A. A.

A NEW METHOD OF PRODUCING A COATING OF MAGNETIC OXIDE ON IRON SURFACES.

By GEORGE R. TWEEDIE.

It will be remembered that last May I had the pleasure of laying before the readers of the *CHEMICAL NEWS* a few details respecting Mr. Geo. Bower's process for producing a coating of magnetic oxide of iron by the action of hot air.

A continuation of the experiments has led to the patenting by Mr. Bower of a second process of considerable interest.

It was ascertained, during the time the experiments with the air process were being carried out, that the magnetic oxide was formed by the oxygen of the air combining with the carbon of the iron and forming carbon dioxide, which in presence of the heated iron was split up according to the well-known reaction—

This fact readily explained why the process was unsuitable for wrought-iron or steel.

It was then resolved to carry out a further series of experiments bearing on this fact, and the best means of applying it practically. Pure carbon dioxide prepared in the usual way was first tried. A silvery coating of magnetic oxide was formed after an exposure of about seven hours at a dull red-heat; the coating, however, was crystalline and somewhat brittle, although very hard.

Very long and tedious sets of experiments were then carried out with mixtures of carbon dioxide and air, air and carbonic oxide, and varying exposures of the three together.

The following is the method of procedure now adopted, and which answers most satisfactorily:—The articles are first of all heated, and acted on for a certain period by the products of combustion largely mixed with air from a peculiarly constructed furnace (designed by Mr. Anthony

Bower), burning slack or small coal. In this way a coating of magnetic oxide is formed close to the surface of the iron, but this is often slightly covered with red oxide, Fe_2O_3 . The admission of air to the furnace is then so arranged by a suitable apparatus that a stream of carbonic oxide is passed over the articles for a short time, and the red oxide very speedily reduced to magnetic oxide,—

It is worthy of note that although the red oxide, before reduction to magnetic oxide, is very readily detached from the iron, after the reduction the Fe_3O_4 so formed is perfectly hard and homogeneous. From all appearances it would seem as though a kind of fusion took place, but at the same time it must be recollected that the temperature used (a red-heat) is very low to favour such an adhesion.

The oxide formed by this process has been tested very thoroughly, and withstands the ordinary oxidising influences perfectly.

Mr. Bower has several contracts in hand which are to be dealt with by his processes, and will present opportunities for the practical testing of the two processes from a commercial point of view.

ON THE INFLUENCE OF VARIATIONS OF TEMPERATURE ON THE DEVIATION OF POLARISED LIGHT BY SOLUTIONS OF INVERTED SUGAR.*

By P. CASAMAJOR.

THE researches, of which I propose to give an account in this paper, were suggested by an interesting communication of Dr. Ricketts to this Society, which was presented at our last meeting.

Dr. Ricketts found that the temperature at which the deviation of a solution of inverted sugar becomes 0 is not $90^\circ \text{C}.$, as given by some authors, but 92° , or rather $91.7^\circ \text{C}.$ From this Dr. Ricketts concluded that if a solution of commercial sugar is inverted in the ordinary way, if originally the two constituents of the sugar were cane sugar and inverted sugar, after inversion there must only remain inverted sugar, and if we bring this solution in the saccharometer tube to have the temperature of $92^\circ \text{C}.$, the indication of the saccharometer scale must be 0.

As the inversion of sugar solutions in testing sugars is now almost entirely neglected, it struck me that the introduction of this subject before this Society was of great importance, as it is likely to excite inquiry in this direction, and must lead to interesting discussions which will throw much light on a ground which has not recently been explored. I hope the following remarks may be considered as a contribution to this important subject.

To enable me to present in a clear light the results I have reached, it becomes necessary to bring before you some theoretical points relating to the inversion of sugar solutions.

It is to Mitscherlich that we owe the observation that the deviating power of solutions of inverted sugar on polarised light varies with the temperature. It is, however, to Clerget that we owe a careful study of the subject. As far back as 1849 he published in the *Annales de Physique et Chimie* (vol. xxvi., 3rd series, p. 175) a process for rectifying errors in tests of commercial sugars by Soleil's saccharometer, by taking into account the deviation caused by a solution of inverted sugar, obtained by heating with hydrochloric acid a sugar solution, previously tested without inversion. In this communication, however, Clerget does not enter into theoretical considerations. He directs that sugar solutions shall be inverted by heating them with 10 per cent of their volume of concentrated hydrochloric acid up to a temperature of $68^\circ \text{C}.$,

* Read before the American Chemical Society, Feb. 6th, 1879.

taking about ten minutes in the operation. As soon as this temperature is reached, the solution is to be cooled down to some temperature between 10° and 35° C., as the table he gives for correction is calculated for temperatures between these limits, which, he says, "answer for all occasions which may present themselves in "Europe, as well as in the Colonies."

When Clerget proposed this new plan for making sugar analysis more correct, the subject of testing sugars was not a new one with him, for it is to him that we owe the idea of using Soleil's polarimeter as a special instrument for analysing sugar, and, as far back as 1845, he had published, in the *Bulletin de la Société d'Encouragement*, an account of Soleil's saccharometer. In his paper in the *Annales de Chimie et de Physique* he gives no theoretical reasons for the new process. For the theory of the correction of the direct test of the saccharometer, by taking into account the test after inversion, I am indebted to some formulas in Maudlebluh's Guide (*Leitfaden zur Untersuchung der Verschiedenen Zuckerarten*, Brunn, 1867, p. 56). This theory I will now proceed to lay before you.

You are aware that commercial sugars contain, besides pure cane sugar, a variety of substances, of which many exert deviating effects on a ray of polarised light. Among these is inverted sugar, which may be an immediate substance or a mixture of dextrose and lævulose. This latter supposition was advanced by Dubrunfaut, but has never been demonstrated in a satisfactory manner, although it would take volumes to collect what has been written about it and is being written about it every day.

The other bodies which accompany cane sugar have not been studied in such a way as to throw light on their nature, with the exception of aconitic acid, isolated by Dr. Behr, who gave an interesting account of his researches in a paper read before the Society two years ago.

A point of great importance in connection with the analysis of sugar by optical methods is that the impurities which are generally present are in such a condition that they seem to exert no effect on polarised light. The proof of this is to be found in the fact that with most sugars, particularly if the saccharometric test is above 90 per cent, the result, after the correction for inversion, is the same as given by the direct test. As many of the impurities reduce the alkaline solution of tartrate of copper, they are comprised under the head of *inactive glucose*, concerning the nature of which there are many unsatisfactory doctrines.

To explain how the direct test by the saccharometer may be corrected by subsequently inverting the solution on which this direct test was made, let us suppose that we have in the first instance a deviation, D . We may suppose that this deviation is the resultant of the following:—

- + C , deviation due to the cane sugar.
- − i " " " inverted sugar.
- + h " " " one or more substances, besides cane sugar, which turn the plane of polarisation to the right.
- − g , deviation due to one or more substances, besides inverted sugar, which turn the plane of polarisation to the left.

Then we may suppose that $C - i + h - g = D$.

In this equation the only known quantity is D , but what we want to know is C . To find this quantity we make use of this fact, that if the solution under examination is heated with 10 per cent of hydrochloric acid, the whole of the cane sugar will be converted into inverted sugar, while the other substances will not suffer any change. From some experiments which I made with artificial mixtures analogous, as far as I could judge, to those which constitute the impurities of commercial sugars, I am led to believe that by heating with concentrated acid a certain change takes place in the deviating power of the impurities of commercial sugars. This change is, however, very

slight, and as the impurities are in small quantities when compared to the cane sugar, the changes they suffer may be neglected, and we may suppose that, with the exception of the conversion of cane sugar into inverted sugar, no change takes place in the other constituents of the commercial sugar from the treatment with hydrochloric acid.

After this action of hydrochloric acid, aided by heat, has taken place, the solution is examined again in the saccharometer, and, after making a deduction for the volume of acid added, we will obtain a deviation, d . This deviation in ordinary sugars will take place on the negative side of the scale. We may suppose that it is the resultant of the same elements that made up deviation D , with the exception of the quantity C , now represented by the deviation due to the inversion of the cane sugar originally present. This quantity we will call $-I$, and we shall have $-I - i + h - g = d$. If now we wish to eliminate the quantities i , h , and g , we may easily do so by subtracting the second equation from the first, and we shall have $C + I = D - d$.

By a series of experiments Clerget established the relation between C and the corresponding value of I . This relation varies with the temperature, but we may suppose that the observation, after inversion, is taken at 28° C., at which a quantity of cane sugar which, before inversion, gives a deviation of 100 to the right, will show for the corresponding inverted sugar 30 to the left or -30 . At this temperature $C + I$ becomes $1.3 \times C = D - d$. As d is a negative quantity the algebraic subtraction is equivalent to an arithmetical addition, whence we draw the rule that at 28° C., the true quantity of sugar C is equal to the sum of the two deviations divided by 1.3, as—

$$C = \frac{D - d}{1.3}$$

This number 1.3 corresponds, as we have said, to 28° C. We may in the next place inquire: What are the corresponding numbers for other degrees of temperature? This brings us to the consideration of Clerget's table. For temperatures between 10° and 35° C., Clerget determined these numbers, and on consulting his table we find that for a quantity of cane sugar equal to 100 we must take for the quantity $D - d$ at 10° C., the sum 139, and that for every degree C. above 10° , up to 35° , the number representing the arithmetical sum of the deviations is equal to 139 minus one-half the difference between the number representing the temperature and 10° . Thus for 20, we have $20 - 10 = 10$ and $139 - \frac{10}{2} = 134$; for 28° , we have $28 - 10 = 18$ and $139 - \frac{18}{2} = 130$; for 35° , we have $35 - 10 = 25$, and $139 - \frac{25}{2} = 126.5$, &c.

If the same law should hold good below 10° , we must, to 139, add $\frac{1}{2}$ for every degree below 10° , and this leads us to establish that at 0° , the number corresponding to $D - d$ would be $139 + 5 = 144$. As this number 144 is one of great importance, allow me to recall to your attention that it means that if we have a solution of pure sugar which will produce a deviation of 100 divisions on the positive side of the saccharometer scale, if this solution is inverted by heating with 10 per cent of hydrochloric acid, this inverted solution, if tested at the temperature of 0° C., will, after making the correction for the quantity of acid added, produce a deviation of 44 on the negative side of the scale.

If now we suppose that the law which Clerget found for temperatures between 10° and 35° holds good for all other temperatures, we may easily obtain the deviation to the left of the same solution of inverted sugar at any temperature by subtracting from 44 one half the number expressing this temperature in degrees Centigrade. Thus we shall have for 10° , $d = -(44 - 5) = -39$; for 20° , $d = -(44 - 10) = -34$; for 28° , $d = -(44 - 18) = -30$, and for any temperature, t ,—

$$d = -\left(44 - \frac{t}{2}\right).$$

If now we draw a series of parallel equidistant lines, intersected by another series of lines, also parallel and equidistant, perpendicular to the first, we may take on the horizontal base line or line of the abscissas, a space between two lines corresponding to $x^{\circ}C.$, and we may suppose that the space between two lines of the other series corresponds to a division of the negative side of the saccharometer scale. If now, on every vertical line, starting from the base line, we take a length proportional to the numbers given by the equation—

$$d = -\left(44 - \frac{t}{2}\right),$$

and if we connect the extreme points of all these lengths by a line, we will find that it is a right line, because the equation—

$$d = -\left(44 - \frac{t}{2}\right) = -44 + \frac{t}{2}$$

is equivalent to the equation of the right line, $y = a + bx$, in which $d = y$, $a = -44$, $b = \frac{1}{2}$, and $x = t$.

If now we take again our equation,—

$$d = -44 + \frac{t}{2},$$

we will find that, if the law it expresses holds good to the end, the temperature at which the deviation becomes 0 is $88^{\circ}C.$

(To be continued.)

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, May 10, 1879.

Prof. W. G. ADAMS, President, in the Chair.

New member:—Mr. J. Kestrell Evans.

Mr. WOLLASTON explained the construction of Gower's improved form of Bell's speaking telephone. The older form, made of wood or ebonite, is open to the objections that it has a very weak voice, soon gets out of adjustment from changes of temperature, and requires a twisted hand wire which is liable to break. Gower's form has a comparatively loud utterance, is constant, and does not require to be held in the hand, but may be laid on a table or hung on a wall, a speaking-tube leading from it to the operator's ear or mouth. The "call" for attracting attention is also within the Gower telephone itself; whereas, in the hand telephone it is an auxiliary apparatus. Every organ of the old telephone has been modified to form the Gower. The magnet in the Gower is of a horse-shoe form, very powerful, the two poles being brought very close together, and each pole is mounted with a small coil of fine wire. The diaphragm is much thicker and larger than the Bell diaphragm. The case is of brass, to expand equably, and a speaking-tube is fitted to the front of the diaphragm. The call consists of a musical reed attached to the diaphragm, so as to be opposite a small slit in the latter. To sound the call it is only necessary to send a sharp puff of wind up the speaking-tube, and the reed gives out a note which is heard throughout a room at the distant end. Speaking and cornet music was transmitted by the instrument exhibited, between the third storey over the hall and the meeting. It was very distinct and audible several feet from the receiver. Speaking done some thirty feet from the transmitter was also sent. Conversation was likewise carried on while considerable noise was being made in the room.

Prof. McLEOD remarked that the *timbre* of this telephone was very good.

Prof. W. F. BARRETT then gave an account of some attempts which he had made to overcome the induction

clamour on telephones caused by the ordinary telegraph currents on neighbouring wires. He had tried recently the Bell telephone on a line from Dublin to Armagh, 93 miles long, but the induction noises completely stifled the speaking, whereas the Edison transmitter gave good results. The clamour could be got rid of either by neutralising the induction currents or by eliminating the noises from the speech. He had taken the second line by experiment. Since the vocal currents differ from the induction ones in potential and period, he attempted to make the latter discharge across the line to earth by fine needle points, and from a heated spiral of wire, in a vacuum, leaving the vocal currents to pass on to the receiver, but without success. Also, since the vocal currents are alternately positive and negative, whereas the induction ones are of one sign, he tried to avail himself of the difference in discharging power of positive and negative currents, but without success. He then tried to take advantage of the difference of period or duration of the currents, the induction currents being longer. He therefore tried to break up the inductions by interposing a rapidly rotating current interrupter, and to make the sections of the musical note obtained interfere with each other by means of an acoustic interference-tube, but practically failed in this also. He mentioned these facts for the benefit of others who may be going over the same ground.

Mr. WOLLASTON pointed out that a perfect cure for induction on underground wires consisted in twisting the going and returning wire of the telephone circuit round each other.

Mr. WILSON then read a paper "*On the Divisibility of the Electric Light by Incandescence.*" By Joule's law the amount of heat developed in a circuit of resistance, R , by the passage of a current, $C = C^2R$; where R is the resistance of generators and connections, r , added to the resistance of the light emitter or incandescent wire, P . Therefore, since by Ohm's law,—

$$C = \frac{E}{R}$$

we have—

$$C^2 = \frac{E^2}{(r+P)^2},$$

and—

$$C^2P = \frac{E^2P}{(r+P)^2}.$$

From this equation the value of P may also be determined. C^2P is the amount of heat developed in the incandescent wire. He infers that the smaller the mass of the wire the higher the temperature generated in it, therefore the mass of the wire should be diminished until the fusing-point of the metal is almost attained. The question of divisibility resolves itself into our being able to divide a single incandescent source into a number of smaller ones giving the same total illumination. The author concludes that this can be done by arranging the sub-divided sources in "multiple arc," or parallel circuits, provided the total mass, length, and sectional area of the united sources be the same as in the original single source. The objection that increased radiation from the various sources would diminish the first total of light and heat can be met by making the smaller wires still smaller than is theoretically required so as to generate more heat. The author regards the "voltaic arc" as probably falling under the same law, the mass, however, being smaller in this case.

Dr. COFFIN then exhibited a Trouvé Polyscope, which consists of a small hand incandescent platinum wire electric light, designed for illuminating the more inaccessible cavities of the body in surgical examinations. The current is supplied by a Planté secondary battery, and the light is half enclosed in a small silver reflector, fitted with a convenient handle. The apparatus is portable. Dr. Coffin found that it was open to several objections, which he has remedied. First, the heat generated made the lamp so hot

that it could not be held to the body for more than a very short time. He overcame this by making the reflector of double silver plates, and circulating water between by means of india-rubber pipes from a bulb which can be worked by the patient himself, thus serving to distract his attention from the operation. Secondly, the secondary battery exhausts itself in twenty minutes, and the light therefore goes out, while from twelve to twenty-four hours are required to re-charge it. Dr. Coffin has superseded it by a Leclanché battery of 8 elements, made by Messrs. Coxetter and Sons, in which the carbon pole is replaced by a copper plate faced with platinum, and no porous diaphragm is employed. This gives a constant light for hours.

NOTICES OF BOOKS.

A Manual of Practical Chemistry: the Analysis of Foods and the Detection of Poisons. By ALEXANDER WYNTAR BLYTH, M.R.C.S., F.C.S., &c. London: C. Griffin and Co.

THE first portion of the title of this book, when standing alone as it does on the back, scarcely leads the reader to expect what is accurately enough described in the second part. The work consists of two somewhat distinct sections, the one treating of the analysis of foods, with especial reference to their impurities—intentional or accidental—while the other is devoted to the detection of poisons. Thus we have before us what might be pronounced two distinct treatises, whose bond of union is mainly due to the bookbinder.

At the same time we feel perfectly free to admit that each of these parts has been compiled in a judicious and conscientious manner. In dealing with adulterations the author has selected the best and most recent methods; he has appended certain useful legal decisions, and under each chapter he has given the bibliography of the subject. We are pleased to see that Mr. Blyth does not under-rate the difficulties of food analysis and of toxicology; he addresses himself to chemists, and does not, as some earlier writers have pretended to do, seek to make every man his own analyst.

In speaking of the analysis of milk we find that he, like most practical authorities, is able to confirm the substantial invariability of the "solids not fat" as existing in unsophisticated samples. He admits that the publication of a normal standard allows a certain amount of watering to be practised, but he fears that the bulk of commercial milk in this country is below the lowest estimate of the Society of Public Analysts. We must, moreover, warn him that it is not in all cases safe to discuss and criticise, even approvingly, published analytical processes. We have heard of one case where such criticism, which necessarily involves quotation, was met with the threat of an action for infringement of copyright! The remarks on unhealthy and abnormal milks are very interesting. The author considers it demonstrated that a disease similar to, if not identical with, tuberculosis may be propagated from animal to animal by means of the milk derived from a diseased cow. He considers that phthisis is very rare among cattle, and that when so affected their milk rapidly decreases in quantity. The chemical qualities of the milk secreted during cattle plague, pleuro-pneumonia, and anthracoid affections have not been duly ascertained.

The adulteration of tea Mr. Blyth thinks is substantially effected abroad, and is decreasing.

Turning to the toxicological section, we find a remark quoted from Dr. F. Mohr, which though mainly judicious is on one point open to question. This distinguished chemist says—"What relation sal-ammoniac, saltpetre, alum, tartaric, citric, and acetic acids, &c., have to toxicology we cannot conceive." Yet, unless we are greatly mis-

taken, a fatal case of poisoning is on record from an over dose of tartaric acid, taken by mistake for Epsom salts. Poisons are conveniently classed by the author under four heads—those which cause death almost immediately, irritants, irritant-narcotics, and poisons affecting the nervous system. The fourth group is again subdivided into narcotics, delirians, convulsives, and those producing complex nervous phenomena.

We cannot but consider it singular that though chrome is mentioned among the irritant poisons no instructions are given for its detection. This is the more to be regretted, as chromium compounds are used in the arts on a vast scale, and are present in the waste-waters from dye and colour works, &c., whence they may find their way into streams, wells, &c. Potassium bichromate, even applied externally, often produces unpleasant symptoms—a fact very familiar wherever "chrome-blacks" are much dyed.

In the section on animal poisons we find a most interesting account of the secretion of the cobra, which the author has carefully examined. The active principle is not a "germ" or organised ferment, but a well-defined and stable chemical compound, which Mr. Blyth has isolated and named provisionally cobric acid.

The whole work is full of useful practical information, and as far as we have been able to perceive it may be regarded as trustworthy. An exceedingly valuable feature—we believe original—is that the various pleas which may probably be raised on behalf of a supposed adulterator or poisoner are here pointed out, and the expert is thus forewarned. We have also very full instructions as to the various channels through which different poisons may be introduced into the human system.

A defect which we hope to see remedied in a future edition is the prevalence of typographical errors. The late Professor Gorup-Besanez is converted into Gorop Besaner; Crantz, the historian of Greenland, becomes "Crzaut," &c. In a tabular view of the composition of coffees from different localities, taken from a German source, some words are left untranslated. Thus we read of Jamaica and Ceylon "Plantagen." It should be "Plantations."

CORRESPONDENCE.

THE VITRIOL MANUFACTURE,

To the Editor of the Chemical News.

SIR,—Dr. Lunge seems to have misunderstood the purport of my letter. I did not intend to prove that an appreciable loss was actually experienced in the Glover tower; I wrote to point out that all fear of appreciable loss of nitre in the Glover tower had not yet vanished. I published some figures simply to show the possibility of such a loss being quite appreciable.

It would not from my point of view be necessary to reply to Dr. Lunge at all, since his remarks flow from this misunderstanding, but as some of these remarks are directed against my ability of weighing arguments, I feel it a duty to myself to make the following statements.

Until very recently the loss of nitre was by no means generally understood to be to so large an extent due to the reduction of nitrogen compounds. For example, Lock's Treatise on the Manufacture of Sulphuric Acid, dated 1879, decidedly inclines to the belief that Mr. Davis's views on the subject are the best explanations yet given of the loss of nitre. Dr. Lunge's treatise, just published in German, lays more stress on the loss of nitre incurred by reduction to nitrous oxide in the chambers. But the whole tenor of the explanations given of the reactions causing such loss is such as to produce the impression that these reactions occur only in isolated places in the chambers, viz., near the steam-jets, and is not at all calculated to give an idea of the magnitude of this loss, which Dr. Lunge now puts down at 75 per cent of the

nitre used. An attempt to give a measure of the loss even if only approximately, I have not found in this exhaustive and very able treatise. I consider it therefore a gain to have elicited from so high an authority as Dr. Lunge the admission (even if conditionally only) that the amount of nitre lost in a manner not yet clearly understood is 75 per cent, or more, of that used.

This "big margin" of course is affected by all the errors in estimating the losses from other sources, but it is quite certain that the statements I furnished err on the right side. Dr. Lunge differs from me only in the distribution of this "big margin." Whereas I think a portion of nitre (and I have many reasons for thinking so) is decomposed in the Glover tower, Dr. Lunge considers the whole of it destroyed in the chambers. He would have been more consistent if he had used a similar phrase to one occurring in his treatise, to the effect that certainly the Glover tower is in this respect no worse than any other denitrator.

To some extent, however, Dr. Lunge seems still to think that part of the "big margin" must be accounted for by the oxidation of arsenious acid to arsenic acid in the Gay-Lussac tower, when, he remarks, that my views conflict with "very careful investigations of M. Hjelldt." But permit me to point out that these "very careful investigations" are of the same type as Mr. Davis's. Both authors discovered arsenic acid in Gay-Lussac vitriol, both came to the conclusion that it was due to oxidation by nitrous anhydride at the expense of an equivalent of nitric oxide. Neither of the two gives experimental proof of this assertion; while Mr. Davis tries to find the resulting nitric oxide in the exit gas of a number of works, M. Hjelldt is satisfied with simply calculating the probable loss of nitre due to this supposed reaction. I have attempted in more ways than one to oxidise arsenious acid by means of nitrous acid in presence of strong sulphuric acid. I have allowed the reagents to act for seventy-two hours at ordinary temperature, and for several hours at temperatures up to 230° F., without being able to obtain a single bubble of any gas, either nitrogen, nitrous oxide, or nitric oxide. I have after repeated experiments come to the conclusion that arsenious acid cannot be oxidised to arsenic acid in presence of strong sulphuric acid so easily as to constitute a source of loss in the manufacture of sulphuric acid. Thus I am convinced that the "big margin" must be accounted for otherwise. Where the whole of the nitre is introduced into the Glover tower there remain only this apparatus and the chambers for the distribution of the loss.

Dr. Lunge thinks my fallacy consists in not having brought forward one particle of proof that any part of this "big margin" must be accredited to the Glover tower, and he produced, what is no doubt meant to be an excellent proof, that the whole of it must be ascribed to the chambers.

Dr. Lunge cites the results of two French works. In one of these (Scheurer-Kestner), where no Glover tower is used, 4.7 of nitre per 100 of sulphur were consumed, and Dr. Lunge calculates that 75 per cent were decomposed inside the chambers. If that is really so, how could the other works (Maletta, of Rouen) where nearly the same amount of nitre was used per 100 of sulphur, save 35 per cent of the nitre, simply by introducing a Glover tower. There would on Scheurer-Kestner's basis be at the outside 15 per cent to be saved, and based on Dr. Lunge's calculation I should say that the introduction of a Glover tower in Scheurer-Kestner's works would, as far as denitration is concerned, be practically useless. Dr. Lunge evidently has forgotten to charge Scheurer-Kestner's denitrator with part of the loss incurred. For a saving of 35 per cent in such works is only possible if the mode of denitration formerly in use is more disastrous than that by the Glover tower.

I have no experience of any other method of denitration except that by the Glover tower, and for ought I can say to the contrary it may be the very best form of deni-

trator, but that does not imply that the Glover tower is perfect, nor exclude the possibility of improvement.

In estimating the share of loss of the chambers I made use of Mr. Davis's figures. Mr. Davis defended these very figures as those he was most sure of. I have, however, some results of daily testings extending over three months of the exit gas of a set of chambers having neither Glover nor Gay-Lussac tower attached, and these results show that the amount of nitrogen escaping in form of its acids is within a small amount (20 per cent) equivalent to the nitre potted. All the conditions which are necessary to cause a reduction of the nitrogen compounds to a lower degree of oxidation than nitric oxide I conceive to be present in the Glover tower to an equal, if not a greater, degree than in the chambers. The sulphurous anhydride here in its greatest concentration is associated with all the steam evolved in the Glover tower, to react upon nitric oxide in the nascent state at a temperature much higher on the average than that of the chambers.

I can see no valid reason in what Dr. Lunge has brought forward to arrive at the conclusion that the loss in the Glover tower has "vanished into thin air," or, as he formerly expressed himself, is as small as a "differential quotient," whatever that expression is meant to convey. Still less can I see any great wisdom in so easily acquitting the Glover tower of all share in the destruction which is evidently going on in the system, and for which, I am fully convinced, the chambers are not wholly responsible. —I am, &c.,

FERDINAND HURTER.

Laboratory, Gaskell, Deacon, and Co.
Widnes, May, 1879.

THE VITRIOL MANUFACTURE.

To the Editor of the Chemical News.

SIR,—I do not wish to take up more of your space than I am obliged, but it seems to me necessary to state that in testing vitriol exits by a continuous system a Bunsen pump and meter is not necessary. An 8-litre bottle properly arranged is more than sufficient for eighteen hours' work, and if that quantity of gas be drawn out in such a manner as to accurately sample the whole number of cubic feet of gases passing, one cubic foot, or even less, will serve every purpose. One cubic foot of the exit gases in many of my experiments has been a sample of at least 1,200,000 cubic feet passing away. But what I principally want to point out (and which I did point out in my last, only it seems to have vanished in transit) is that both Hurter's and Lunge's theory of the chemical loss of nitre in the chambers will not work. Hurter ascribes 20 per cent loss, due to the action in the chambers. Lunge says 75 per cent. Now let us examine both of these.

A works with five large chambers was making 100 tons of vitriol per week, and they were using to produce this 3 tons of nitrate of soda per week; they used no towers, made always a good production from the ore burnt, and the escaping oxygen was 6.2 per cent by volume of the exit gases. The total acidity of the exit gases was always low—about 2.3 grains of Na_2CO_3 neutralised by one cubic foot. After working in this way for some years this firm decided to erect one denitrating column and two absorbing columns: directly they started to work there took place a great reduction in the quantity of nitre used, and the normal quantity soon became 16 cwts. per week.

Now let us examine these results closely, and the amount of nitre destroyed by the chambers must be reckoned on the original quantity used before the towers were erected, as your correspondents have not inferred that the introduction of towers will cause the destruction of nitre in the chambers to be any less, and we have no published experiments which even hint that this might be the case. These chambers, then, actually used 60 cwts. of nitrate of soda per week.

Hurter states twenty per cent is destroyed in the chambers; this is equal to 12 cwts.

Lunge states 75 per cent of the loss takes place in the chambers themselves; this is equal to 45 cwts.

Now the putting up of the towers can scarcely be thought to have exerted any influence upon the nitre-decomposing power of the chambers, as the drips and acids were worked to be of the same strength as before their erection. What was then the total nitrate of soda used weekly? 16 cwts., or 29 cwts. less than Lunge says the chambers alone will decompose. Lunge's theory, then, must evidently be a false one.

Hurter states that the chambers would decompose 12 cwts., leaving 4 cwts. to be accounted for in other ways. But he has accounted for them, and let us see how his theory works:—

Decomposed by chambers; 20 per cent of the	
60 cwts. used	12 cwts.
Withdrawn from system by exit gas; 10 per	
cent of the 26 cwts. used	1.6 "
Loss by imperfect denitration; 10 per cent of	
the 16 cwts. used	1.6 "
Loss from leakage; 5 per cent of the 16 cwts.	
used	0.8 "
Total loss	16.0 "
Total used	16.0 "

So that even on Dr. Hurter's own figures there is no nitre left for his theory of destruction in the towers.

I am glad that Dr. Lunge endorses my views with regard to the escape of nitric oxide. Many chemists have found it in company with oxygen, and if they will come forward and state their views I am willing to give the experiments which I have upon the subject.—I am, &c.,

GEORGE E. DAVIS.

Heston Chapel, near Stockport,

PROBABLE BEHAVIOUR OF VARIOUS METALS AND THEIR COMPOUNDS WHEN SUBJECTED TO RAPID OXIDATION.

To the Editor of the Chemical News.

SIR,—Having received much assistance from chemists, and knowing the interest taken by them in the experiments which have been made at the works of Messrs. Charles Cammell and Co., Penistone, and at those of Messrs. John Brown and Co., Sheffield, I venture to hope that I may be favoured by the advice and assistance of some of your readers as to the probable behaviour of various metals and their compounds when subjected to rapid oxidation.

We will assume that the charges treated consist of sulphides, arsenides, &c., and contain a sufficient proportion of oxidisable materials to produce the necessary heat for their fusion, decomposition, and volatilisation of the sublimes. That iron, lead, gold, silver, copper, nickel, antimony, zinc, arsenic, and sulphur are present as well as sufficient silica to combine with the protoxide of iron produced, so as to form $2\text{FeO}, \text{SiO}_2$, and also an additional quantity of silica with the necessary lime or other bases to neutralise same so as to form a slag of specific gravity 3.4.

To avoid giving unnecessary trouble, I will briefly state my ideas as to their behaviour, and I trust your readers will kindly correct any errors I may make, as by so doing they will greatly oblige me, and thus assist me in my further experiments.

The Iron would be partially or entirely oxidised, and combine with the silica so as to form $2\text{FeO}, \text{SiO}_2$ + silicate of lime, &c.; part of the iron might remain in the regulus as FeS and Fe.

The Lead would probably distil off and be collected as PbS; but it is possible that metallic lead might be reduced by the PbO produced reacting on PbS, i.e.,—

If metallic lead is produced it would collect in the quiescent

hearth, and with it would be found the gold and silver, and probably some metallic copper.

The Nickel and Copper would be concentrated into a regulus, and would contain all the silver and gold, unless metallic copper or lead was reduced. If not too much oxidised the regulus would contain $\text{FeS} + \text{Fe}$, and if the oxidation was prolonged metallic copper would result, with which would be found all the silver, but I am not clear as to the gold. I should have supposed that the gold and silver would have gone together, but in an experiment at Penistone, July 17, 1878, a small quantity of metallic copper was produced, which Mr. Edward Riley found to contain 201 ozs. 4 dwts. 12 grs. of silver per ton, but only traces of gold, at the most 2 dwts., although the regulus from which it was produced contained 1 oz. 2 dwts. 20 grs. of gold per ton.

The Antimony and Zinc would be volatilised and collected as oxides.

The Arsenic would probably distil off as sulphide of arsenic, although part might be oxidised to arsenious acid.

The Sulphur not found in the regulus or combined with arsenic would partly distil off as sulphur, and the remainder would be oxidised and pass off as SO_2 .—I am, &c.,

JOHN HOLLOWAY.

London, E.C., May 10, 1879.

OBITUARY.

THOMAS WILLS, F.C.S.

MANY of our readers will have heard with regret of the very sudden death of Mr. Thomas Wills, who has acted as Secretary to the Chemical Section of the Society of Arts since it was first founded in 1874. From the *Journal* of the Society we learn that Mr. Wills was born in 1850, in Devonshire; he was educated at University College School and at King's College. In the early part of 1868 he became an assistant to Dr. Odling at St. Bartholomew's Hospital, and in the latter part of that year, on Dr. Odling being elected to the Fullerian professorship at the Royal Institution, Mr. Wills was appointed his official assistant. In 1873 he accepted the position of Demonstrator in Chemistry at the Royal Naval College. The subject to which he specially devoted himself was the application of chemistry to the manufacture of gas, and on questions connected with this subject he was rapidly becoming an authority. He held for some time the position of chemist to the Phoenix Gas Company. In 1873, previous to his official connection with the Society of Arts, he read a paper on "The Manufacture of Gas," and last year he gave a short course of lectures before the Society on "Explosions in Coal Mines." For several years he acted as Secretary to Section B of the British Association, and he was a member of the Association Committee for ascertaining the best methods of improving the illuminating power of coal gas. His most recent piece of work was in connection with the subject of electric lighting. Dr. Tyndall, in giving evidence upon the electric light before a Committee of the House of Commons, referred to Mr. Wills as having discovered that oxides of nitrogen were given off by the voltaic arc, thus rendering the light to that extent injurious. His death was most sudden and unexpected. He fell a victim to typhoid fever, which carried him off after an illness of less than a week. He was only twenty-eight years of age at the time of his death.

New Books.—The first volume of "A Treatise on the Manufacture of Sulphuric Acid and Alkalies," by Prof. Lunge, will, we understand, be published very shortly by Mr. Van Voorst. The work will be fully illustrated, and be complete in two volumes. The same publisher has in the press a supplement to Mr. C. Greville Williams's "Handbook of Chemical Manipulation."

MISCELLANEOUS.

South London School of Pharmacy.—The prizes for the Second B. Course were presented on Saturday, the 3rd inst., by the Secretary, Mr. W. Baxter, to the following successful competitors:—Senior Chemistry: Medal, Mr. Newbigin; Certificate, Mr. Lemmon. Junior Chemistry: Medal, Mr. Scammell; Certificate, Mr. Stevens. Botany: Medal, Mr. Betts; Certificate, Mr. Dutton. Materia Medica: Medal, Mr. Cook; Certificate, Mr. Stedman. Pharmacy and Practical Dispensing: Medal, Mr. Stevens; Certificate, Mr. Cook.

The Coal Tar Colours.—At the meeting of the Chemical Section of the Society of Arts, held on Thursday, the 8th inst., Mr. W. H. Perkin, F.R.S., read the first part of a paper on "The History of Alizarine and Allied Colouring Matters, and their Productions from Coal Tar." In this he gave a brief account of madder and its applications to calico printing, Turkey red dyeing, &c., and then proceeded to treat of alizarine and purpurin, the colouring matters of madder. He then gave a history of the discovery of their artificial production from anthracene, a hydro-carbon from coal tar, and the new processes by which it had been found possible to manufacture these bodies on the large scale, as well as the allied colouring matter, such as anthrapurpurin, &c. The subject was illustrated with experiments and specimens of the products referred to, as well as patterns dyed with the various colouring matters. The reading of the second part of the paper has been postponed from the 15th until the 22nd, when the history of the practical methods of carrying out this important manufacture will be dealt with.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 14, April 7, 1879.

Iodides of the Stannopropyls.—A. Cahours.—The author had formerly described a supposed iodide of sesquistanpropyl. He finds that it is a mixture of the diiodide of distannopropyl and of the iodide of tristannopropyl.

On Complementary Spinners.—E. Chevreul.—If a circle, one diametrical half of which is painted with any colour *a*, and the other half left white, is made to revolve at a speed between 60 and 160 turns per minute, the complementary colour of *a* appears on the white half. The author proposes these spinning disks as tests for colour blindness.

Focus of Heat Produced by Molecular Shocks.—W. Crookes. Presented by M. du Moncel.

Reply to M. Flammarion on the Declination of the Magnetic Needle.—Marié-Davy.—The author ascribes the anomalies pointed out by M. Flammarion to the methods employed in the calculation of the means in his tables.

The Gravi-volumeter.—A. Houzeau.—The gravi-volumeter is employed in a method of analysis which enables us to perform certain determinations not within the reach of ordinary volumetry. The author states that by its means he can determine with exactness and in less than twenty-five minutes the sulphates in a natural water, operating upon 10 c.c. without previous concentration. The instrument cannot be intelligibly described without the aid of the accompanying figure.

Detection of Fire-damp in the Atmosphere of Mines.—MM. Maillard and Le Chatelier.—The authors propose a lamp burning hydrogen gas, the feeble light of

which does not mask the blue flame produced by fire-damp within the gauze of safety-lamps. In this manner a proportion of hydrogen proto-carbide as low as 0.25 per cent is easily recognised.

Certain Conditions of Lactic Fermentation.—Ch. Richet.—The presence of oxygen facilitates the fermentation of milk. Up to 44° a rise of temperature intensifies fermentation. From that point up to 52° there is no modification, and above that point the fermentation slackens. Digestive juices augment the rapidity of lactic fermentation.

Amylaceous and Amyloid Granules of Eggs.—M. Dastre.—The author maintains that the amyloid bodies of M. Dareste are not starch and have not even its appearance. He remarks that micro-chemical reactions are not always trustworthy in cases of substances saturated with albumen and fat, and thus rendered impenetrable to reagents.

Determination of Sugar in the Blood.—M. d'Arsonval.—The author points out that the criticism put forward by M. Cazeneuve on methods employed by the late Claude Bernard have already been refuted. He states that greenish reductions betray either bad reagents or a defective manner of operating, and ought never to occur.

Methods Employed by Cl. Bernard in Determining Reductive Sugars in the Blood.—P. Picard.—The author admits that there exist in the organism, along with reductive sugars, other substances capable of acting upon Fehling's test, but he doubts if such can exist in the liquid obtained by the preliminary treatment adopted by Cl. Bernard? He considers that a saccharimetric examination of animal matter can lead to no accurate results as there are a great number of substances possessing a rotatory power.

Distribution of Phosphates in the Different Elements of the Blood.—L. Jolly.—The alkaline phosphates predominate in the serum, whilst phosphate of iron, though present in all the constituents of the blood, is especially accumulated in the globules.

The Formation of a Peculiar Amyloid Principle Peculiar to the Asci of Certain Pyrenomycetes.—L. Crié.—As a rule fungi possess no starch, but *Sphaeria Desmazieri* contains an amyloid mass formed in darkness by a protoplasm devoid of chlorophyll.

MEETINGS FOR THE WEEK.

- MONDAY, 19th.—Society of Arts, 8. "Recent Advances in Telegraphy," by W. H. Preece. (Cantor Lectures.)
Royal Institution, 3. "The Intellectual Movement of Germany from the Middle of the Last to the Middle of the Present Century," Prof. Hilkebrand.
- TUESDAY, 20th.—Civil Engineers, 8.
Royal Institution, 3. "Suggestions to Students and Readers of History," Prof. J. R. Seeley.
Society of Arts, 8. The Adjourned Discussion on Mr. W. Lloyd Wise's Paper on "The Government Patent Bill" will be resumed.
Zoological, 8.30.
- WEDNESDAY, 21st.—Society of Arts, 8. "Edison's New Telephone," Conrad W. Cooke.
Pharmaceutical, 8. (Anniversary.)
- THURSDAY, 22nd.—Royal Institution, 3. "Dissociation," by Prof. Dewar.
Society of Arts, 8. "The History of Alizarin and Allied Colouring Matters, and their Production from Coal-Tar," by W. H. Perkin, F.R.S.
Zoological, 4.
- FRIDAY, 23rd.—Royal Institution, 9. "Multiple Telegraphy, or Duplex and Quadruplex Telegraphy," Mr. W. H. Preece.
Society of Arts, 8. "The Harbour of Kurachee," W. J. Price, M.L.C.E.
- SATURDAY, 24th.—Royal Institution, 3. "On Swift," Prof. H. Morley.
Physical, 3.

TO CORRESPONDENTS.

ERRATUM.—Vol. XXXIX., p. 190, line 37, read "the former together with the H₂S set free," &c.

H. Allen.—The paragraphs were quoted from foreign journals, and it is impossible always to trace them to their proper source.

THE CHEMICAL NEWS.

Vol. XXXIX. No. 1017.

ON THE ELIMINATION OF PHOSPHORUS IN THE BESSEMER CONVERTER.*

By SIDNEY G. THOMAS, F.C.S., and
PERCY C. GILCHRIST, Associate Royal School of Mines, F.O.S.

THE non-removal of the phosphorus in the Bessemer converter, owing to which the great bulk not only of British, but of French, German, and Belgian ores, are still unavailable for steel-making, is a fact too familiar to metallurgists to need insisting on. The inquiry whether this unfortunate circumstance is due to causes absolutely inseparable from the conduct of the Bessemer process, or to others which are merely the accidents of a particular mode of constructing the apparatus, is obviously of vital importance. If the non-elimination be due to the intensity of the temperature, or to the short duration of the operation, or to both these causes combined, it is almost hopeless to expect that we shall ever be able to use ordinary unpurified pig-iron in the converter.

That it is to these essential accompaniments of the process that the phenomenon of the retention of phosphorus by Bessemer metal is to be ascribed is, it is believed, the generally received opinion, and one which has comparatively recently received the sanction of the weighty authority of such eminent metallurgists as Mr. Lowthian Bell, Dr. Wedding, Prof. Kerl, and M. Euverte.

An examination of the general condition attending the removal of phosphorus in puddling and refining operations, taken in connexion with the well-known action of silica on phosphate of iron at high temperatures, and the fact that in many other processes in which the temperature is very high the elimination of phosphorus is not apparently effected, seems, however, to justify the belief, which has doubtless suggested itself to other members of this Institute, that it is to the siliceous lining of the ordinary converter, and to the consequent necessarily siliceous character of the slag, that one defect of the Bessemer process is due. Under this conviction, at all events, experiments were commenced by the authors about three years ago on the effect of basic lining and basic additions in the several steel-making processes. Unfortunately the appliances at command were of a very imperfect character, and the results obtained, though highly encouraging, were, owing to defects in the miniature converter employed, which prevented our ever completely finishing a blow, not entirely conclusive as to commercially complete purification being possible.

While waiting the completion of an improved converter, which was unavoidably delayed for some time, we were encouraged by finding that M. Grüner, the distinguished professor at the Ecole des Mines, of Paris, in his "Treatise on Steel," published in 1867, laid great stress on the injurious influence of the siliceous character of the cinder and lining in the converter. M. Grüner, however, seems at that time to have regarded this as one only of three causes which prevent elimination of phosphorus, and proposes as a remedy the preliminary refining of phosphoretic pig before it is attempted to convert it.

With a new converter, a large number of experiments were made in the autumn of last year, which gave much more definite results. The lining used in these experiments consisted of limestone and silicate of soda, a mixture which had been found to answer well in earlier trials.

On laying some of the first of the results obtained from

* A Paper read before the Iron and Steel Institute. (Condensed.)

this six-pound converter before Mr. Martin, of Blaenavon, he at once recognised their importance, and from that time we have been deeply indebted to him for his unflinching and consistent support, and much valuable advice and assistance. The Blaenavon Company, also, without hesitation, undertook to put up apparatus to carry the experiments further, and has with great spirit fulfilled its promise to give every facility to test the value of the theory thoroughly.

In a vertical converter, taking from 3 cwts. to 4 cwts. of metal, results entirely confirmatory of those previously observed were obtained. In the six-pound converter liquid decarbonised iron could not be obtained; but in the new vertical converter this was readily done.

Some fifty or more blows were made in this vertical converter, and the products analysed; and it was found that, using a basic lining, it was generally necessary to continue the blow for over forty seconds after the flame dropped in order to bring the phosphorus down very low. With this proviso the elimination of phosphorus could be secured with absolute certainty. With a siliceous lining the retention of all the phosphorus in the metal was, as usual, equally invariable, even when, as in Mr. Bell's experiments, the blow was continued till a considerable proportion of the iron was oxidised. At the same time, more phosphorus and less silica would be found in the slag obtained under these conditions than appears to be the case when large quantities of metal are treated under similar circumstances.

Using a lining consisting of one part fire-clay and two of ganister, and a pig containing 1.44 per cent of phosphorus, the blown metal contained 1.63 per cent of phosphorus and the slag 32.5 per cent of silica, and 0.85 per cent of phosphorus. When, however, with the same lining, 40 lbs. of lime was placed in the converter before the pig was run in, though the lining wore away very much (as might be expected, there was a decided decrease of phosphorus in the blown metal, as shown below:—

P.	P.	P.	SiO ₂ .	CaO.
Pig used, 1.44	Blown metal, 1.23	Slag, 0.99	30.7	18.8
" —	" 1.07	" 1.81	31.0	25.1

It would seem that the presence of a considerable amount of lime in a not too siliceous slag is highly favourable, and on a large scale essential, to the removal of phosphorus. As it was manifest that phosphorus was not removed until the slag was sufficiently basic, the effect of large basic additions in combination with a basic lining was tried, with the object not only of obtaining a highly basic slag at an early stage of the blow but of rendering the operation independent of the wear of the lining by which alone the basic character of the slag is otherwise obtained and maintained. Advantage was taken of the fact that lime and oxide of iron are fusible in many proportions. The mixture generally used consisted roughly of one part by weight of "Blue Billy" and two of lime; this will melt in an iron crucible, and may be readily added in a molten condition. It was found that by throwing into the converter cheap basic materials consisting mainly of lime, even without previous heating, before the pig was introduced, very satisfactory results were obtained without over-blowing.

By using these basic additions, a large proportion of the phosphorus is eliminated while yet a considerable proportion of the carbon remains, a result which had otherwise only been obtained when there was a very considerable waste of lining.

With a 12-cwt. converter of the ordinary pattern, expressly put up by the Blaenavon Company, only a limited number of casts were made, owing to a deficiency of blast.

By the kindness of Mr. Menelaus, for whose kindly assistance we have to tender our sincerest thanks, we were enabled to try, at the old No. 3 pit at Dowlais, if the superior intensity of heat which might be expected from

the conversion of 5 or 6 tons of metal at a time affected the conclusions to which smaller experiments pointed. It was intended to line this converter with highly burnt basic bricks. The bricks intended for this purpose were, however, accidentally under-burnt, and so spoilt; hence recourse was had to a rammed lining of limestone and silicate of soda. This lining, which consisted of a siliceous limestone mixed with 9 per cent of a solution of silicate of soda, would, after the carbonic acid was driven off, contain nearly 20 per cent of silica. This, by greatly diminishing the effect of the ordinary wear of the lining in making the slag basic, rendered larger basic additions necessary than it was deemed prudent to make in the first two blows. In the first blow about 2 cwts. of lime were added cold, and in the second nearly 2 cwts. of lime and 1 of Bona ore. The slag was decidedly siliceous in both cases, and, of course, only a minute quantity of phosphorus was removed.

Blows.	Pig Used.		Blown Metal.		Steel.

P ..	1'21	1'21	1'21	1'19 under	1'11	1'11
C ..	—	—	none	0'10	0'54	0'42
S ..	0'06	0'10	0'50	0'10	0'05	0'09

Mr. Jenkins, of Dowlais, has kindly furnished us with his analyses of the same blows. He finds 1'08 in the steel from the first blow, and 1'03 in the steel from the second blow.

The cinder with the steel contained in the first blow 38·8 per cent of silica, and in the second blow 36'8. The pig used was too high in silicon for phosphorus to be readily removed, without very large additions of lime.

In the third blow $3\frac{1}{2}$ cwts. of a mixture of two parts of lime to one of roll scale were thrown into the converter before the metal was run in. The metal was blown for eight or nine minutes and turned down (before the flame dropped). Nearly another $3\frac{1}{2}$ cwts. of the same mixture was then thrown in, and the vessel again turned up, when the flame dropped almost immediately. After being turned down for some fifty seconds, it was (at Mr. Martin's suggestion) again blown for nearly a minute. Though it appeared that the metal was overblown, the action, on adding spiegel, was not violent. A large skull was, however, left in the converter and ladle, and much slag was produced. The blow lasted ten and a half minutes. A rail made from one of the ingots deflected 98 inches with the blow of 1-ton ball falling 24 feet, the bearings being $3\frac{1}{2}$ feet apart. It was considered much too soft for rails.

The skull left in the converter was got out by blowing a charge of very siliceous non-phosphoretic pig. In the next (fifth) blow, 1 cwt. of a mixture of two of limestone and one of Elba ore was thrown cold into the converter before the metal was run in; rather over 3 cwts. of heated roll-scale was added subsequently, before the completion of the blow. During this blow the lining had to be patched at the breast.

The results appear to confirm the conclusion that, for the process to be of technical value, waste of lining and metal must be avoided by making large basic additions, so as to secure a highly basic calcareous slag at an early stage of the blow. In these trials, however, it was thought prudent to feel the way, and not add at once the very large amount of base which our theory demanded, the more so as we were not able to add the bases in the molten state. It is also made clear that a slag containing under 24 per cent of iron may be very effective in removing phosphorus.

After the five blows described the lining was found to be much worn, and not in a condition to admit of satisfactory repairs. Two tuyeres had to be renewed in the fourth blow; the rest stood well.

It is obvious that without a sufficiently durable, as well as refractory, basic lining, the simultaneous dephosphor-

isation and conversion of cheap pig in the Bessemer vessel cannot rank as a commercial process. Our early experiments rendered it clear that ordinary non-siliceous lime and limestone did not constitute by themselves a satisfactory lining material; nor were renewed trials, made after becoming acquainted with a patent dealing with their application, more successful. Magnesia, the use of which as a furnace lining has been suggested by M. Caron and others, is at once very expensive and—when used by itself—very tender. Nor did we, after repeated attempts, find it at all practicable on the large scale to use oxide of iron linings in any of the forms in which they have been used in puddling furnaces. After a very extended series of trials* it was, however, found that, by firing bricks made of an aluminosiliceous limestone at a very intense white heat, a hard and compact basic brick is formed. These bricks unfortunately labour under the defect of a liability to disintegration when exposed to the action of steam. By the use of certain aluminous magnesian limestones and equivalent combinations, and an otherwise similar mode of manufacture, this difficulty has been overcome. For certain purposes magnesian limestone, mixed with silicate of soda solution, forms an excellent material. To enter fully into the important subject of the precise conditions necessary for obtaining a satisfactory basic lining would exceed our limits, and the consideration of this, as of many other interesting points, must be reserved. The question of how far the heat due to the oxidation of phosphorus may replace that due to the combustion of silicon, the possibility of using in the converter low phosphoretic pig low in silicon, and the influence of silicon on the removal of phosphorus, are some of the subjects on which much remains to be said.

In advancing the proposition that the technical removal of phosphorus in the Bessemer converter is simply and entirely a question of cheaply producing a highly basic slag, containing under 20 per cent silica and over 30 per cent of lime and magnesia, and indicating the means by which this may be secured, we are not aware that we can shelter ourselves under any very distinct authority, though surmises as to the hypothetical advantages that might be expected, were the Bessemer slag less siliceous, have not been wanting. It is, however, only proper that we should remind the Institute that Mr. Snelus stated at its March meeting simultaneously with ourselves that he had removed phosphorus in a Bessemer converter lined with limestone. Of the circumstances of this experiment we are in ignorance. It is on the production of a basic earthy slag, by the addition of large quantities of calcareous bases, and without excessive waste of lining and metal, and the construction of a durable basic lining, that we venture to think the economic solution of the phosphorus problem depends.

It need hardly be said that the theory here advanced as to the practicability of commercially removing phosphorus in the converter extends, *mutatis mutandis*, to the Siemens and other open-hearth processes, where, in fact, many difficulties that are met with in the converter are absent. Dr. Siemens has indeed suggested the use of a lime lining in one of his furnaces, though he has since, with his customary candour, informed us that he has failed to devise means for its successful application. The present paper will have fulfilled its purpose if it induces metallurgists to reconsider the verdict, so fatal to the hopes of steel-makers, that "oxygen, whether in its free state or as oxide of iron, is almost entirely inert as regards phosphorus at the intense temperature which accompanies the Bessemer process."

In the nine months that have elapsed since our paper on the "Elimination of Phosphorus," &c., was prepared, the vigorous co-operation of Mr. Windsor Richards and

* For most valuable assistance in these, as at every period of this investigation, we are especially indebted to Mr. Thomas Griffiths, engineer at Blaenavon. We take the opportunity of at the same time thanking Mr. Gill, assistant in the Blaenavon laboratory, for his aid in the many hundreds of analyses made in the course of our inquiry.

Messrs. Bolckow Vaughan has enabled the authors to submit to the Institute further evidence in support of the views then put forward. That intensity of temperature is no obstacle to the removal of phosphorus, but, under proper conditions, highly favourable to this end, has been abundantly demonstrated by the results of the working at Middlesborough. It is indeed found that, other things being equal, the hotter the blow the better is the result. As regards the necessity for large additions of bases consisting mainly of lime, the experience afforded by some seventy or eighty operations is equally conclusive.

In continuation of some smaller experiments carried out in 1877 at Blaenavon, trials have been made of the effect of largely increasing the amount of oxide of iron added at the commencement of the blow, and diminishing the lime so as in a measure to assimilate the cylinder to that of a puddling furnace. As was anticipated, it was found that this could not be done successfully. In the first place, the loss from excessive boiling was very great; in the second, the phosphorus is only very imperfectly removed. A very considerable amount of ore may, however, be added after the greater part of the silicon is removed. The amount of bases which it is necessary to add with Cleveland pig generally exceeds considerably 2 cwts. per ton of pig treated, the exact amount being dependent on the wear of the bottom, and the percentage of silicon and phosphorus in the pig. The presence of an excess of earthy base in the slag seems an essential condition of success. The formation of a very fluid basic slag at an early stage of the operation is also of great importance, as it enables the phosphorus and carbon to be oxidised *pari passu*, or nearly so. It will be borne in mind that the basic addition has a double function; in the first place, to preserve the lining; in the second, to form a highly basic earthy slag, so as to afford a strong base with which the phosphoric acid may unite at the moment of its formation. On several occasions the experiment has been made of blowing in a basic brick lining without, or with very small, addition. The result is always excessive damage to the lining and a trifling removal of phosphorus. The density and compactness of the present lining material prevents it from playing the important part in the actual formation of the basic slag which was fulfilled by the softer and less durable linings first experimented on. The highly-fired magnesian lime bricks have, we venture to think, more than fulfilled all the expectations which were entertained as to their probable value.

It has also been ascertained that, providing a highly earthy basic slag is present, the removal of almost the last traces of phosphorus may be secured by continuing the blow for some time after the drop of the flame. The phosphorus in the presence of a strong base seems to protect the metal much in the same way as carbon and silicon, so long as there is present an excess of a strong base with which the phosphoric acid can unite at the moment of its formation. When, however, the phosphorus is reduced very low, the iron begins to oxidise as in an ordinary case of over-blow.

The question of the elimination of phosphorus being the primary matter with steel-makers, it is not proposed to do more than to mention that, under the circumstances which have been described as essential to the removal of phosphorus, a considerable proportion—viz., from 30 to 70 per cent—of the sulphur is also removed. Certain experiments made by the authors in conjunction with M. Ponsard, in November last, with a Ponsard furnace,—in the first of which over 80 per cent of the phosphorus and 50 per cent of the sulphur were removed under very unfavourable conditions,—quite confirm the opinion formed from smaller experiments, that the system described is as applicable to the open-hearth as to the Bessemer furnace. Those open-hearth furnaces which are provided with removal hearths offer peculiar facilities for the adoption of brick hearth or lining.

PEROXIDE OF HYDROGEN.*

By GEORGE E. DAVIS.

Most books tell us that H_2O_2 is made by a roundabout process with BaO_2 and HCl ; this might have been in days gone by, but now it is made principally by means of barium peroxide and hydrofluoric or fluosilicic acids. An insoluble fluoride of barium or fluosilicate is formed which separates at once and peroxide of hydrogen remains.

Now, if hydrofluoric or hydro-fluosilicic acids have been used, we need not expect to find hydrochloric, as this latter can only be present when impure fluoride is used, impure acids, or impure water. Of course it is absolutely necessary to examine carefully every sample of peroxide of hydrogen which may be purchased, for many statements have been made at various times respecting the purity of the bought article. One chemist assured me that the first lot he purchased was full of hydrochloric acid, whilst another chemist actually assured me that peroxide of hydrogen would not oxidise sulphide of sodium in vat liquors. More statements than these have been made respecting the efficiency of this reagent, but in each and every case it would have been more creditable to the author of the statement had he examined thoroughly the facts of the case before making complaint against one of the most useful articles used in chemical analysis.

Now, the first thing which requires to be estimated is the active oxygen, and this may be seen when I state that the sample which would not oxidise sulphide of sodium contained only a trace of active oxygen. Many methods may be devised for estimating the strength of this article. I have used the following three methods with satisfactory results:—

1 c.c. was put into Crum's tube over mercury and run underneath the tap; then 5 c.c. of a saturated solution of bichromate of potash, the whole gently agitated, the liberated oxygen measured and corrected for temperature and pressure. In working on a certain sample as a mean of several experiments, 1 c.c. gave 8.2 c.c. of oxygen at $0^\circ C.$ and 760 m.m.

By a second method 10 c.c. of the peroxide were boiled with 20 c.c. of sulphurous acid, and the sulphuric acid which was formed precipitated as barium salt and weighed; the sulphuric acid existing as such in the sulphurous acid being deducted from the precipitate. 10 c.c. oxidised 0.46 grm. SO_2 , or 7.08 grs.

By a third method 10 c.c. of the peroxide oxidised 146 c.c. $\frac{N}{10}$ protosulphate of iron. Now, if we calculate these we shall find that our first method gives the strength of the solution as 8.2 volumes, and they all, when expressed as in grammes of oxygen per litre, show:—

- a. 11.72
- b. 11.53
- c. 11.68

For general work the bichromate method is preferable, though when extreme accuracy is required the iron method may be employed if conducted in a stream of carbonic acid.

Now, as to the stability of peroxide of hydrogen. It has been stated quite recently, and by one of the members of this Club, that it is so unstable that simply drawing air through a solution of it will abstract the whole of its active oxygen. I don't know what amount of air is considered necessary, but I should say a great deal, and neither do I know what tests he used to ascertain that there was no peroxide left undecomposed. An alkaline solution of peroxide is partly decomposed by agitation only, but an acid or neutral solution is very stable. An alkaline solution of peroxide has been used over a very long time in connection with a continuous aspirator, 10 c.c. of peroxide and the necessary quantity of water

* A Paper read before the Faraday Club.

aspirated through at a speed of 15 cubic feet per twenty-four hours has shown an excess of peroxide at the finish of the experiment, even when caustic soda was present in excess also. I have evaporated a 10-volume solution of peroxide to half its bulk without driving off more than two-thirds of its active oxygen, but when reduced to that bulk caustic soda was added, the elimination of oxygen was so violent as to amount almost to explosion. When kept in solution in the laboratory a 10-volume solution of peroxide is moderately stable. During 1878 the following tests were made of a sample by the bichromate method over mercury:—

August 2	9'0
" 9	8'4
" 24	8'0
September 1	7'9
" 24	7'8
October 24	7'2

A few drops of ether were now added to 250 c.c. of that sample of October 24, and the following tests continued:—

November 7	7'2
" 24	7'2
December 1	7'2
" 24	7'2

Ether seems to preserve it, a fact which has been known for some time. This was also mentioned to me by Dr. Messel, of Silvertown, in August, 1878, a method I have used ever since. It is stated in all our text-books that peroxide of hydrogen is neutral to test-papers. Now, all commercial peroxide is faintly acid with the excess of hydrofluoric or hydrofluosilicic which is added and which should be estimated in each sample before using it.

I have used peroxide of hydrogen since 1873, and latterly in comparatively large quantities, and I have made it a rule to examine each purchase as follows:—100 c.c. of the peroxide was evaporated to dryness with 10 c.c. N soda, ignited, and taken up again with water. N acid was then added to neutrality, chromate of potash, and finally titrated with $\frac{N}{10}$ nitrate of silver. The results of many experiments upon this one sample showed that 100 c.c. of peroxide neutralised 0'2 c.c. of N soda and consumed 3'4 c.c. of $\frac{N}{10}$ nitrate of silver. On the evapora-

tion to dryness of the peroxide by itself a very pungent acid is liberated, and which can be easily told is not hydrochloric. In order to show the moderate stability of peroxide of hydrogen, I have lately had a sample sent me of commercial peroxide which was at least fifteen months old. When treated with bichromate over mercury it gave 7 volumes of oxygen, and I know that no special care, or indeed care of any kind, was bestowed upon the sample.

Having, then, a ready method of testing its contained amount of active material, it remains only for me to show that peroxide of hydrogen is an exceedingly useful oxidising agent, for it oxidises by reason of its loosely combined oxygen, and when an excess is added to any substance or to any solution, that excess is readily eliminated, leaving only as a residue that most neutral substance water.

There are many substances often seen in the laboratories of alkali works that cannot be readily and accurately examined except by its use; such as the total alkali and crude soda liquors or in black-ash, and certain qualities of soda-ash which contain sulphides or sulphites. In the testing of chamber exits it is extremely useful, inasmuch as sulphurous acid is not an acid easily titrated, for the normal sulphite of an alkali is not neutral to test-paper, and therefore on titrating a sulphite with a standard acid the point of neutrality is not clearly defined and distinct. This want of clearness in the ending has been stated by some chemists to be due to the carbonic and nitrous acids

present in chamber exits, but add peroxide of hydrogen to the solution and all difficulty vanishes, the sulphurous acid is oxidised to sulphuric, which acid is easily titrated.

I will now proceed to give examples of its use in various methods of analysis. Some samples of soda-ash contain so much sulphite of soda that it is impossible to estimate the amount of alkali accurately by means of standard acid. As an example of this kind of ash I give the following analysis of a sample of ash made from caustic salts, which contained by the acid test in the ordinary way 30 per cent of alkali without peroxide of hydrogen, whilst the addition of a few c.c. brought down the actual percentage to 21. The escaping carbonic acid carries away a great deal of sulphurous acid, but it does not do this if peroxide of hydrogen is present.

Sodium sulphide	0'098
" sulphite	22'982
" sulphate	2'207
" chloride	33'048
" silicate	1'214
" carbonate	18'704
" hydrate	12'800
Water	8'747

99'800

Peroxide of hydrogen is very useful in the analysis of black-ash; a few c.c. added to the liquor under examination gives at once the total alkali, which number needs no correction for sulphides, hyposulphites, &c.

This reagent is very useful for many laboratory oxidations, such as the oxidation of iron salts, colouring matters, experiments on bleaching, &c., &c. In fact the applications of this useful substance are legion. I first commenced to use this reagent for testing vitriol exits in 1873; but its application then was very limited as I had to make my own, and a perfectly pure peroxide of barium is not a very easy thing to make. In those days peroxide of hydrogen was looked upon as a sort of *rara avis*, to be found only in the laboratories of schools of chemistry, and its use was not much extended until a pure peroxide of hydrogen entered the market as a commercial article, to be bought and sold in the same way as other reagents.

Heaton Chapel, May 12, 1879.

EXPLOSIONS IN FLOUR-MILLS AND COAL-MINES.

By WATSON SMITH, F.C.S., F.I.C.

I BELIEVE it was about the year 1871 that the great explosion took place at the Tradeston Flour Mills, near Glasgow, but not having any particulars with me here, I cannot speak with absolute certainty as to exact date. As this was a catastrophe attended with loss of life and great damage to property, a searching investigation was made into its causes. Several theories were propounded, but none appeared to be satisfactory or to meet the circumstances but the one which I was enabled to give. This explanation was suggested to me on reading a short note in *Dingler's Polytechnisches Journal*, of which an abstract appeared under the head of "Technical Chemistry" in the *Journal of the Chemical Society*. The author, who wrote from Austro-Hungary I believe, had noticed how artificial lightning was made in theatres by blowing lycopodium seed through a flame, and he found that dry flour would also do for the purpose. Then he argued that flour dust in quantity might also be caused to flash off, given a due admixture of air and the introduction of a spark or flame. In this way he sought to account for sundry explosions in flour-mills in his part of the world. The sparks might be struck by the stones coming into slight collision, or incautious approach with a naked flame might fire the

mixed atmosphere of the stove-room in a flour-mill. The explanation I gave, which appeared in the *Glasgow Herald*, was based on this, and, so far as I know, I think I may claim priority as to the bringing forward of this view, as far as either Great Britain or America are concerned; at least I understood the Scottish Royal Society's Commission of Inquiry on the subject gave me at the time the credit of it. The drift of my explanation was the following:—"If the grinding-stones be supposed to get slightly out of gear at any time, as they quite possibly may, they may come in contact with each other so as to strike sparks amongst the fine flour-dust suspended cloud-like in the atmosphere immediately in the neighbourhood of the stones. Such an attenuated combustible mixture as flour-dust suspended in air approaches the condition of a mixed gas, and, the proportions being favourable, an explosive mixture. The whole atmosphere of the stove-room is often laden with this dust. Now, imagine a single grain of flour-dust inflamed by contact with a spark from the stones, or by a naked flame brought into the room, what is to hinder this inflammation from passing instantly, and like a flash, from grain to grain, the atmospheric oxygen supplying a common means of combustion? quite analogously to the case of an explosive gaseous mixture. Carbonic acid and steam are thus generated suddenly, and at an elevated temperature, and the sudden expansion in a closed space, like the interior of a mill, produces the pressure resulting in disastrous explosive effects."

Berthelot has calculated that the sudden increase of volume which may take place is amply sufficient to account for explosions. Under certain normal condition, in which great rapidity in the revolution of the stones is attained, and the grain is unusually dry, one can even, with Mr. L. Smith, conceive that sufficient heat may be developed to cause ignition, especially if some hard foreign body—such as a piece of wood, for instance—by any accident should get in with the grain in grinding. Its attrition and pulverisation might, perhaps, cause ignition of the dust produced. Still, an abnormal rapidity of revolution would also, in case of slight collisions of the stones, cause showers of sparks to fly, or an ordinary lantern or bare flame might be brought into the room, and these would be quite sufficient to inflame the atmosphere, given favourable proportions of flour-dust and air existent at the time. This it seems to me is an explanation nearer at hand, and also more probable than the other.

Mr. Langbeck in his paper (*CHEMICAL NEWS*, vol. xxxix., p. 191), though thinking himself justified "in opposing these explanations and substituting another one," neither, in point of fact, does practically oppose them, nor does he offer anything in substitution but an unlikely surmise—a mere "smell of impure hydrogen," on which opinions again might differ. This surmise he tries to support by experiments, which, however, on the whole, go more to second the explanations already given above than his own. The experiment with the coal-gas, as recorded, is abortive to prove anything on the subject; and, finally, his opposition to the explanation given, and his substitution of another one is a complete fiasco, for he winds up asking the way to the source of his own surmise. Having attained this, but failing to find his way out of it again, he puts it to the reader to find the way out for him in a couple of questions further. And this is opposing an explanation and finding a substitute! To both questions I for one would reply "Certainly, No!" as far as the case in point is concerned. If one of them were admissible it might surely be expected that explosions should occasionally be heard of in our bakers' ovens. Perhaps Mr. Langbeck is not aware that a well authenticated explosion is on record caused by the falling of the contents of a flour-sack. The cloud of flour-dust came in contact with a gas-flame, and a very considerable explosion occurred. The *Journal of the Chemical Society* of London for this month contains a brief account of Berthelot's views on the subject.

It is now a pretty well ascertained fact that some

otherwise slight coal-mine explosions may be expanded into great disasters, owing to the clouds of coal-dust raised into and diffused through the atmosphere of the workings; such an atmosphere, especially in presence of traces of fire-damp, being thus suddenly converted into an explosive mixture. This view, too, explains the frequently observed fact that an explosion in a coal-mine often sweeps over very considerable tracts of the workings. I am told that Prof. Marreco, of Newcastle, has investigated and experimented on this subject.

It has occurred to me that in view of these similar causes of, and liability to, explosions, both in flour-mills and in coal-mines, the electric lamp would be the best and safest means of illumination that could be employed. Such a light could be confined in a glass globe, hermetically sealed, and would be a fixture of course. Means of signalling could also be adjusted in coal-mines. Thus most stringent and rigorous measures would be rendered feasible to prevent the introduction of matches, lights, or lamps and lanterns of any kind into the workings. At the present cost of the electric lamp it might also with advantage be used in the stove-room of flour-mills, and others where clouds of flour-dust may be raised at any time. This recommendation may of course have been already made; if so I have not observed it, and on this ground may plead excuse for failing to acknowledge prior claims.

Zürich, May 9, 1879.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, May 15, 1879.

Dr. WARREN DE LA RUE, President, in the Chair.

THE minutes of the previous meeting were read and confirmed. The following certificates were read for the first time:—C. J. Wilson, G. S. V. Wills, W. H. Kerr, G. R. Tweedie.

THE PRESIDENT then called on Mr. WAREINGTON to read a paper "On Nitrification (Part II.)." A. Müller was the first to advance the opinion (*Chem. Soc. Journ.*, 1873, 1267) that nitrification is due to the action of a ferment. Schloësing and Müntz proved this to be the case (see Part I. of the author's paper), and from recent experiments show that soils which induce nitrification have this power destroyed by exposure for one hour to 100° C., and that ordinary moulds and mycodermis injure rather than promote nitrification. The author also mentioned that the above experimenters were at present engaged in an attempt to isolate and cultivate the organism, which promised good results. The objects of the author were to ascertain the influence of light, temperature, variations in the composition, and concentration of the solutions on the process of nitrification, the rate at which it progresses, and the relation of the nitric acid produced to the ammonia consumed. In nearly every case exposure to light prevents nitrification, and in all cases the exposure hindered the process to a marked extent. The mould which develops in a solution containing tartrates is incapable of effecting nitrification. The presence of carbonate of calcium seems to be indispensable to the growth of the ferment. The author pointed out the significance of this fact as explaining the absence of nitrites and nitrates in soft peaty waters, and as bearing on the utility of applying lime, &c., to peaty soils rich in nitrogen, in a form unfavourable for absorption by plants. A very small amount of organic carbon is requisite. An extensive series of quantitative experiments is given as to the effect of temperature. The upper limit of temperature at which nitrification takes place has not been determined. 40° C. is,

however, fatal to the process, which can proceed at 10°, and probably at still lower temperatures. In all cases there is a period after the addition of the ferment during which no appreciable effect is produced. This period the author terms the period of incubation. This period is considerably shortened by increasing the temperature. Thus, in a solution containing 640 milligrams. AmCl per litre the period was at 10° 78 days; at 30°, 19 days. As the solutions become stronger the period increases. Thus, a solution containing 80 milligrams. the period was only 31 days at 10°, or 12 at 30°, instead of as above 78° and 19°. The presence of bacteria does not promote nitrification. The author discusses the interesting question why in some cases nitrites, and in others nitrates, are produced. When the ammonia disappears before the nitrous acid is converted into nitric acid, the nitrites left in solution are very stable: if, however, the oxidation of nitrites sets in before the ammonia has been consumed nitrates are formed with great rapidity. In no case is the whole of the ammonia obtained as nitric acid. Some experiments were made as to the part played by the heating effect of the sun's rays in preventing nitrification, as a temperature of 40° proved to be fatal. It was found that a solution sheltered partially from the heat, by a screen of alum solution, but fully exposed to the light, of the sun, nitrified sooner than a similar solution exposed to the heat and light. In both cases nitrites were formed which were very permanent. The paper concludes with some interesting experiments on the conversion of nitrites into nitrates by the ferment. This change apparently takes place only in the dark, and a ferment which is quite competent to convert ammonia salts into nitrites is apparently not necessarily competent to convert the nitrites into nitrates. Some solutions, however, which are nitrifying seem to possess this power in a high degree. The progress of nitrification is not uniform; it begins slowly, increases in rapidity, and after reaching a maximum again diminishes. The strongest solutions nitrified by the author contained 180 parts of nitrogen per million.

The PRESIDENT said the author had investigated the subject with great acumen. It was interesting to observe that the process might produce either nitrites or nitrates.

Dr. WRIGHT then read a paper "On the Alkaloids of the *Veratrum* Family (Part III.)," by C. R. A. WRIGHT and A. P. LUFF. Alkaloids of *Veratrum album*.—The authors have examined the alkaloids extracted from 12 kilos. of dried roots by percolating with alcohol acidified by tartaric acid (1 part per 200 of roots), evaporating to a small bulk, addition of water, filtration from resin, and treating with a slight excess of caustic soda and ether. After repeated washing with ether an insoluble precipitate was left, which seemed to consist principally of a base hitherto undescribed, which the authors name pseudo-jervine, $C_{29}H_{43}NO_7$. It is snow-white, and melts at 299°, crystallising anhydrous from alcohol; with sulphuric acid it gives a yellow solution, gradually turning green. The ethereal solution contains, besides small quantities of pseudo-jervine, several other alkaloids, which can be separated by shaking the crude ethereal solution with aqueous tartaric acid, and treating the mixed tartrates with soda and a smaller bulk of ether: a residue is left, containing pseudo-jervine, an amorphous alkaloid named by the authors Veratralbine, and Jervine. Jervine, $C_{26}H_{37}NO_3$, forms a sulphate almost insoluble in hot and cold water. It crystallises with two molecules of water, melts at 239°, and gives with sulphuric acid the same colours as pseudo-jervine; the sulphate of pseudo-jervine is, however, tolerably soluble in water. The second ethereal solution deposits on spontaneous evaporation crystals of jervine mixed with another base, which forms a readily soluble sulphate. This base gives with sulphuric acid a red colouration, hence the authors suggest the name Rubijervine. It melts at 237°, and resembles in many respects pseudo-jervine; forms with crystallised salts, and crystallises anhydrous as $C_{26}H_{43}NO_2$. The ethereal mother-liquor of these crystals dries up to a varnish consisting

chiefly of veratralbine, $C_{28}H_{43}NO_5$. A small quantity of another base is present, yielding veratric acid on saponification. The mixture of veratralbine and this base is powerfully sternutatory, but this property is lost by boiling with alcoholic potash. Hence it is probable that the sternutatory constituent is veratrine (Couerbe). Neither jervine, pseudo-jervine, rubi-jervine, nor veratralbine excite sneezing. Veratralbine gives with sulphuric acid a red colouration resembling that given by cevadin and veratrine. No evidence of saponification or other decompositions was obtained on boiling these bases with alcoholic potash, the minute quantity of supposed veratrine excepted.

Dr. WRIGHT then read a paper "On the Alkaloids of the *Veratrum* (Part IV.)." Alkaloids of *Veratrum viride*.—On treating about 18 kilos. of dried roots precisely as described in the foregoing paper, the first treatment with ether left undissolved some pseudo-jervine, the tartrates obtained from the ethereal solution yielded no veratralbine, but jervine crystallised out from the second ethereal solution on standing. Traces of rubijervine were observed. The ethereal mother-liquors dried up to a powerfully sternutatory amorphous mass, closely resembling the "veratralbine" similarly obtained from *V. album* roots. It gave on analysis, however, $C_{32}H_{49}NO_9$, the formula of cevadin, and on saponification it yielded about the theoretical quantity of cevadic acid with a trace of veratric acid. The following table represents the approximate yield of the different bases from the two roots per kilo.:-

	<i>V. album</i> .	<i>V. viride</i> .
Jervine	1.30	0.20
Pseudojervine	0.40	0.15
Rubijervine	0.25	0.02
Veratralbine	2.20	trace
Veratrine	9.05	less than 0.004
Cevadine	apparently absent	0.43
	4.20	0.80

The jervine and pseudo-jervine from *V. viride* agreed in melting-point, properties, analytical numbers, &c., with the specimens obtained from *V. Album*.

Dr. WRIGHT then read a third paper "On the Alkaloids of the Aconites (Part IV.)." by C. R. A. WRIGHT and A. P. LUFF. Japanese aconite roots.—The authors have examined two different batches of roots, treating them with alcohol acidulated with tartaric acid, evaporating, adding water, making alkaline with sodium carbonate, and then shaking with ether. Repeated treatments with ether failed to dissolve all the alkaloid present, some being obstinately retained by the alkaline fluid; this appeared to be ac-crystalline. The ethereal extract, after purification by shaking with aqueous tartaric acid and treatment of the crude tartrate solution with soda and fresh ether, gave by spontaneous evaporation crops of crystals. These crops were fractionated and re-crystallised; all gave numbers indicating the formula $C_{56}H_{88}N_2O_{21}$. Treatment with hot concentrated tartaric acid failed to produce any change in the analytical numbers, whence the authors conclude that the substance is not a mixture of two bases, $C_{33}H_{45}NO_{11}$ and $C_{33}H_{43}NO_{10}$. The authors have named this base Japaconitine. It melts at 185° to 186°, and closely resembles aconitine. On saponification it splits up into benzoic acid and a new base, Japaconin. Japaconin closely resembles aconin, but on treatment with benzoic anhydride it forms a tetrabenzoylated instead of a dibenzoylated derivative. A tetrabenzoylated body is also formed by heating japaconitine with benzoic anhydride, aconitine giving a dibenzoylated body. The authors adopt the following view as to the constitution of japaconitine, admitting the existence of a base—

$$\begin{array}{c} (\text{C}_{26}\text{H}_{39}\text{NO}_2) - \text{O} \text{C}_7\text{H}_5\text{O} \\ | \qquad \qquad \qquad // \qquad \qquad \qquad \text{O} \\ | \qquad \qquad \qquad \text{O} \\ | \qquad \qquad \qquad // \qquad \qquad \qquad \text{O} \\ \text{C}_{26}\text{H}_{39}\text{NO}_2 - \text{O} \text{C}_7\text{H}_5\text{O} \end{array}$$
$$(\text{C}_{26}\text{H}_{39}\text{NO}_7) \begin{array}{c} \diagup \text{OH} \\ = \text{O} \\ \diagdown \text{OH} \end{array} .$$

Dr. WRIGHT, in reply, said that he was not convinced as to the identity or otherwise of his alkaloid and the one obtained by Paul and Kingzett. From the data given by the above authors he had stated that the properties, &c., of their alkaloid agreed with those of pseudoacotin, and he still held to this statement. He had only withdrawn it as far as his own alkaloid was concerned, which was certainly not pseudoacotin. He did not dispute the accuracy of nitrogen determinations by volume, but if only a per

The SECRETARY then read a "*Preliminary Note on some Reactions of the Ammonio-chloride of Magnesium known as Magnesia Mixture*," by H. D'ANCY POWER. The author has observed that most potassium and some sodium salts precipitate magnesium hydrate from a solution of ammonio-chloride of magnesium. Potassium iodide possesses this property in a marked degree. Thus the addition of 15 c.c. of a 10 per cent solution of potassium iodide with 10 c.c. of ammonia to 5 c.c. of magnesia mixture (prepared by dissolving 5 grms. of magnesium oxide in 40 c.c. of hydrochloric acid, and then adding 60 c.c. of ammonia and filtering), after standing twenty-four hours gave a precipitate which, when washed and ignited, weighed 0.046 grm.; it was pure MgO, so that 46 per cent of the total MgO was precipitated. Potassium bromide gave under similar circumstances a precipitate weighing 0.002 grm. Further results are promised.

The two following papers were taken as read:—

"*The Composition of Cows' Milk in Health and Disease*," by A. WYNTER BLYTH. The results of this research are the separation of two alkaloidal bodies as normal constituents of milk; the separation of a substance, probably a glucoside, derived from plants, &c., eaten by the cow; a quantitative estimation of the different constituents of milk; analyses of samples of milk derived from cattle in an unhealthy state. The separation of the milk alkaloids:—A litre of milk is divided into three equal parts, to one of which a litre of water is added, the casein is precipitated in a flocculent condition by the cautious addition of acetic acid, and, finally, by passing carbonic acid, a clear yellow whey is obtained, which is separated by decantation and filtration and used to precipitate the second portion; the whey from this is similarly used to precipitate the third portion of milk. The yellow whey is boiled and filtered to get rid of albumen, and to the filtrate an excess of the solution of nitrate of mercury used for urea estimation is added. The precipitate which falls contains the two alkaloids, any albumen, and urea as mercury compounds. It is washed and decomposed with sulphuretted hydrogen, &c. The first alkaloid, which the author proposes to call Galactine, is thrown down by acetate of lead; the lead salt has the composition $(\text{PbO})_{23}\text{C}_{54}\text{H}_{78}\text{N}_4\text{O}_{45}$. Galactine is a white, brittle, neutral, tasteless, non-crystalline mass, soluble in water, insoluble in alcohol; it is precipitated by Sonnenschein's and Scheibler's reagents. Excess of lead used to precipitate the galactine is removed and nitrate of mercury added, which throws down an alkaloidal colouring matter. Lactochrome, the empirical formula of the mercury salt, $\text{HgOC}_6\text{H}_{18}\text{NO}_6$. Lactochrome is a bright red-orange resinous body, softening at 100° , soluble in water and hot alcohol. In addition to these alkaloids the author has separated two substances, CH_3O_3 and $\text{C}_3\text{H}_3\text{O}_4$, reducing copper solution, which he regards as decomposition products of one substance, and as derived from food eaten by the cow. They are obtained by precipitation with ammonia and tannin, after separating the above alkaloids. The author gives the following as the average composition of healthy cow's milk:—Milk-fat, 3.50 per cent (oleine, 1.477; stearin and palmitin, 1.75; butyrin, 0.270; caproin, caprylin, and rutin, 0.003); casein, 3.93; albumen, 0.77; milk-sugar, 4.00; galactine, 0.17; lactochrome, not determined; bitter principle, 0.01; urea, trace; ash, 0.70 (K_2O , 0.1228; Na_2O , 0.0868; CaO , 0.1608; Fe_2O_3 , 0.0005; P_2O_5 , 0.1922; Cl , 0.1146; MgO , 0.0243); water, 86.87. As regards milk from diseased cows the author concludes that a cow suffering from even very acute disease may give milk differing in no essential feature from normal milk, whilst local affections of the udder may often be easily recognised. Analyses of milk from cows suffering from mammitis, pneumonia, phthisis, &c., are given.

"*Notes on the Effect of Alcohol on Saliva and on the Chemistry of Digestion*," by W. H. WATSON. The author finds that ptyalin is more rapidly or effectually precipitated from simple aqueous solutions than from saliva. The separation is aided by heating to 100°F . 18 grs. of absolute alcohol added to 200 grs. of saliva and 10 grs. of starch produced in an hour less extractive matter by about one-quarter than a similar mixture containing no alcohol; a similar reduction in the quantity of sugar produced was also effected by the addition of alcohol. The author made some experiments as to the effect of slightly acidulating the mixture of starch and saliva with hydrochloric acid. He arrived at the following conclusions:—By the addition of a small amount of acid the action of the saliva is decidedly increased, while the retarding influence of alcohol is not lessened by the presence of the acid. He also points out the bearing of these experiments on the process of digestion in the stomach, where the starchy matters and saliva are mixed with the gastric juice.

During the reading of the last three papers Dr. GILBERT took the Chair.

The Society adjourned to June 5, when the following papers will be read:—"On Gardenip," by Dr. Stenhouse and Mr. Groves; "On the Theory of the Fractional Distillation," by F. D. Brown; "On the Action of Organo-zinc Compounds on Quinones," by F. R. Japp; "On Chlorotannic Acid," by J. W. Mallet; "On Indigo-purpurin and Indirubin," by E. Schunck; "Third Report to the Chemical Society on some Points in Chemical Dynamics," by Dr. Wright and Messrs. Luff and Reanie.

CORRESPONDENCE

DETERMINATION OF NITRIC AND NITROUS ACID.

To the Editor of the Chemical News.

SIR,—In the *CHEMICAL NEWS*, vol. xxxix., p. 205, Mr. Davis quotes a remark of mine on Crum's mercury method (which Mr. Davis calls *his* method, although it was published many years ago, and used by several chemists previously), as if I had not rendered justice to him. I had certainly pointed out that the correction for temperature and pressure is required for something less than "extreme accuracy," as Mr. Davis has put it, considering that it amounts sometimes to more than 10 per cent, and I do not see that I can retract that. I have lately published tables which allow these corrections to be made by a simple reading off, without any calculation (*Dingler's Journal*, vol. cxxxi., p. 522).

With reference to Mr. Warington's paper, read before the Chemical Society at its last meeting, I beg to point out that in the *Berliner Berichte*, vol. xi., p. 439, I have described a number of tests, proving the accuracy of Crum's mercury method for nitrous and nitric acid, for a mixture of both, and for mixtures with arsenious acid and with glucose. In the just-quoted paper in *Dingler's Journal* I have described some precautions required for correctly working the process with my "Nitrometer."

Although Mr. Davis cannot in any sense claim the process as his, yet I have to thank him for bringing it forward again, as I had entirely overlooked it before, and I believe alkali works' chemists were generally in the same situation, and are equally indebted to Mr. Davis.

Would you kindly allow me on this occasion to correct an omission of a few words in my letter, printed in your issue of the 2nd inst., which obscures the meaning of the passage. On p. 194, col. 2, line 5, it should stand—"The total loss of nitre, *apart from that in the chambers themselves*." That this is the meaning of the passage is proved by the sequel.—I am, &c.,

GEORGE LUNGE.

Technical Laboratory of the Federal
Polytechnic Schools, Zürich.

PREVENTION OF ESCAPE OF SULPHUR-GASES DURING THE CHARGING OF PYRITES FURNACES.

To the Editor of the Chemical News.

SIR,—Having erected a set of new furnaces and acid plant seven years ago in the neighbourhood of a town where some of the local authorities were hostile to the manufacture, it was therefore of the greatest importance to prevent any escape of sulphur-gases. I was led to study the best means of preventing the escape during the time of charging. I hit upon a very simple and efficient plan, which had the recommendation of costing nothing. It was simply to close all the ash-pit doors before the door of the furnace to be charged was opened. The necessary draught being forced to enter through the only open door entirely prevents the escape of gas, and the workman

has only to open the ash-pit doors again the requisite distance to admit the proper amount of draught to each furnace. This plan I found to have the advantage of making the fires burn more regularly, as the fireman, from having to open and close the ash-pit doors oftener, had his attention directed to them, and so the draught was better regulated.—I am, &c.,

E. H.

May 20, 1879.
PS.—I may say that the furnaces and ash-pits were furnished with closely-fitting doors.

WASH-BOTTLES WITH CONTINUOUS JET.

To the Editor of the Chemical News.

SIR,—In the *CHEMICAL NEWS*, vol. xxxix., p. 19, Mr. Foye called attention to a wash-bottle giving a continuous jet of water, and Mr. Mallet, in your issue of May 2, has described a more complete but complicated form of the same. In both these cases the essential feature is a piece of caoutchouc tubing, so arranged as to permit the air inside the bottle being cut off from the external air by pressure with the finger. Will you kindly permit me to say that I described a bottle having this arrangement, and also the Bunsen valve, in a paper read before the Chemical Society in March, 1877. A short abstract appeared in your journal. The following is an illustrated description of the wash-bottle:—

It has two tubes fused into it at right angles, which are bent round upon the top of the cork, and connected by a piece of good caoutchouc tubing (*b*). The tube (*a*) is stopped between the two junctions of the side tubes by a piece of cork (*d*), or by being fused up. When the operator wishes to use the bottle he holds it as usual, placing his forefinger upon the caoutchouc (*b*), so as to prevent air passing through it, and blows through the mouthpiece into the bottle. After this the jet of water continues to issue with almost undiminished force for about three-quarters of a minute, while it may be stopped at any time by releasing the pressure upon the caoutchouc tube (*b*). Water may be poured out through the new tube (*a*) as usual. It is convenient to bend the lower end of the tube dipping into the water; this enables the operator to blow out the last portions of water. The advantages of the bottle are as follows:—The jet will issue for some time after the operator has blown into the bottle, and can be directed upwards into a beaker by inclining the bottle. The jet can be stopped at pleasure. The water passing through the new tube when the bottle is inverted can be regulated to a drop by pressing upon the rubber. The mouthpiece never gets hot, nor does gas or steam pass through it into the mouth. When the water is boiling, if the bottle be occasionally

gently shaken, enough steam is liberated to impel the jet. Lastly, the bottle can be used as an ordinary one by blowing into the new tube without pressing the caoutchouc. After the tube (*a*) is made or purchased there is no extra trouble in making the bottle. A caoutchouc stopper is the best to use, but a good cork answers perfectly well. Messrs. Jackson, of the Barbican, at my request have kindly consented to keep a few of these tubes in stock. Several of these bottles have been in constant use for two or three years in the Chemical Laboratory of the Royal College of Science, Dublin, and have given great satisfaction.—I am, &c.,

THOMAS BAYLEY.

14, Mincing Lane, London,
May 5, 1879.

THE VITRIOL MANUFACTURE,

To the Editor of the Chemical News.

SIR,—In the *CHEMICAL NEWS* (vol. xxxix., p. 205) Mr. G. E. Davis has referred to a statement I made to him regarding the loss of nitre. What I said then—I was speaking from memory—was perhaps scarcely justified by the facts; still, the quantity of nitre unaccounted for in our case is very much less than that mentioned by Dr. Hurter. The quantity of nitre used during the six months was 1·66 per cent on the stone burnt, equal to 37·18 lbs. to the ton. If we assume the real nitrate of soda present to be equal to 95 per cent, this would be equal to 35·31 lbs. There was found in the outlets nitrous gases equivalent to 15 lbs. nitrate of soda for each ton of stone burnt, which would give 42·5 per cent on the quantity used, or four times that mentioned by Dr. Hurter. If we add to this 10 per cent for imperfect denitration, and 5 per cent for mechanical losses, we get a total of 57·5 per cent unaccounted for. During the six months these trials were made much acid was drawn from the chambers for manure making, and this acid always contained a quantity of nitre; indeed, so much was this the case on some occasions as to interfere with the workmen while mixing in the vat. It is impossible to say how much was lost in this way, but it will be readily seen that much more than 45 per cent of the nitre is thus accounted for, without putting down 20 per cent as reduced to nitrous oxide, as is done by Dr. Hurter. I may say that we are still finding in the outlets between 40 and 50 per cent of the nitre used. But is it not probable that the different results obtained are due in a great measure to the different way in which the chambers are worked? This we know from experience—that where the chambers are worked with the acid strongly impregnated with nitrous gases much less nitre is required than where the acid in the chambers stinks of sulphurous acid.

Much has been said regarding the state of oxidation of the nitrous gases found in the outlets, but no one seems to have made any direct attempt to ascertain what that state of oxidation is. Directly after Mr. Davis published his observations on the reducing action of As_2O_3 in the absorber, I commenced a series of experiments to settle the question, at least as far as these works were concerned. In all fifty-five tests were made, and out of these in forty-three cases the gases existed as N_2O_3 and N_2O_4 , while in the other twelve the gases existed as N_2O_2 and N_2O_3 . It was necessary in making these experiments to assume that the nitrous gases were present in only three forms of oxidation, viz., as N_2O_2 , N_2O_3 , and N_2O_4 , and that only two of these, either $N_2O_2 + N_2O_3$ or $N_2O_3 + N_2O_4$, were present at the same time. This assumption is, I think, warranted by the properties of the gases, for we should scarcely expect N_2O_2 and N_2O_4 to exist together side by side without reacting upon each other.

Mr. Davis has attributed the presence of N_2O_2 in the outlets to the reducing action of As_2O_3 exerted while the acid is passing down the absorber. Now I have reason to believe that under certain conditions sulphurous acid is competent to reduce the nitrous acids. I give below two

instances, copied from my note-book, which will tend to support this belief:—"The chambers had been working with very great regularity for a length of time, the quantity of nitre used being equal to about 1 per cent on the stone burnt, and the quantity found in the outlets equal to about 12 lbs. on the ton of stone. On the 16th the chambers were looking badly, and I examined the pipe between the absorber and the last chamber when the gases smelt quite sharp. Accordingly, I expected to find a large quantity of SO_2 present (in the test solutions) this morning. I was surprised to find only a trace as usual, while that of nitre had more than trebled, viz., 43·31 lbs. to the ton of stone."

The next case is still more conclusive:—"Two days ago the acid from the absorber contained nitrous acids equivalent to 2·45 per cent of nitre; this morning it contained 1·07 per cent. During this time, the Glover tower being out of repair, has not been working, and it was thought advisable to put the same acid over and over again through the absorber. While this was going on the chambers have been stinking, and it was inferred that a large quantity of SO_2 would be found going away. This has not proved to be the case, as only a trace has been found in the test-bath yesterday and to-day, although 6 cubic feet of the gases have been tested on each occasion. The nitre found in the outlets has been very large, viz., 102·8 lbs. per ton of stone yesterday and 120·7 lbs. per ton of stone to-day."

Now these two cases would point to the fact that SO_2 is capable of reducing the N_2O_3 , in solution in the acid, to N_2O_2 ; thus, $\text{N}_2\text{O}_3 + \text{SO}_2 = \text{N}_2\text{O}_2 + \text{SO}_3$, and that this reaction may take place in the absorber.—I am, &c.,

E. JACKSON.

Laboratory of Messrs. T. Adkins and Co.,
Smethwick, near Birmingham.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 15, April 14, 1879.

Anomaly in Magnetic Observations at Paris.—C. Flammarion.—The author contends that the explanations of these anomalies put forward by M. Marié-Davy are not satisfactory.

Bulletin de la Société Chimique de Paris,
No. 5, March 5, 1879.

Recent Paper by M. B. Aronheim.—P. Schützenberger.—M. Aronheim having stated in the *Berichte der Deutsch. Chem. Gesell.* that on attempting to prepare the acetates of chlorine and iodine he had obtained mere mixtures of acetic and hypochlorous acids, or of chloride of iodine and iodic acid, M. Schützenberger refers to numerous chemists who have seen and examined, or have themselves prepared, the products in question.

Chloro-stannates of the Rare Earths.—P. T. Cléve.—The composition of the lanthanic, ceric, didymic, and yttric chloro-stannates is quite analogous to that of the corresponding chloro-platinates. The author has verified the researches of M. Marignac on the earths of the gadolinite. No doubt can exist concerning terbia. He has obtained a small quantity of ytterbia, but his researches are not completed.

Russian Chemical Society, December 7/19, 1878.—M. Beketoff communicated a paper on the determination of the atomic heat of hydrogen in its combination with platinum. M. Andrianowsky has examined the action of

aluminic chloride upon acetic and sulphuric anhydrid MM. Riordinine and Saytzeff describe diallyl-isopropyl carbinol as a colourless liquid, of sp. gr. 0·8512, boiling-point 182° to 185° . MM. Semianitzine and Saytzeff have investigated the oxy-valerianic acid obtained the oxidation of allyl-dimethyl-carbinol. MM. Beilstein and Kourbatoff have obtained nitro-phthalic acid oxidising nitro-naphthalin by means of chromic anhydrid

Researches on Sulphates.—A. Etard.—The sulphates of the magnesian series, or of the alum series, are from representing all the combinations which sulphuric acid forms with the metals. Many of these salts may be represented by the general formula $\text{M}_2(\text{SO}_4)_6\text{N}_2$. He examined the double sesqui-sulphate of iron and alum (acid); that of iron and chrome (acid); the corresponding neutral salt, &c. The sesquisulphate of aluminium and manganese is a powder of a beautiful sky-blue.

Relations between the Chemical Composition and the Mechanical Properties of Steels.—V. Deshay.—Carbon renders steels rigid and elastic, increasing the elastic tension, but their resistance to rupture diminishes if 0·500 is exceeded. Manganese renders steels rigid and elastic and increases their elastic tension, but the elongation and contraction remain considerable, which give good resistance to a shock. Silicon plays the same part as carbon, rendering steels hard, and slightly diminishes elongation. Sulphur decreases the breaking strain; the resistance to a shock. Phosphorus renders steels deficient in body, and, if its proportion exceeds 0·250 per cent, fragile on receiving a shock. Chrome adds to manganese but more energetically.

Thermic Formation of the Compounds of Carbonic Oxide with the other Elements.—M. Berthelot.—Already noticed.

Specific Heats and Melting Heat of Gallium.—Berthelot.—The specific heat of liquid gallium is 0·08 that of solid gallium 0·079. The melting heat is +19°. The specific atomic heat in the liquid state is 5·59; in solid 5·52.

Reciprocal Displacements of Weak Acids.—Berthelot.

Rotatory Power of Styrolen.—M. Berthelot.—The two papers have been already noticed.

Justus Liebig's Annalen der Chemie,
Band 195, Heft 3.

Products of the Action of Caustic Potassa upon Sulpho-mesitylenate of Potassium.—Oscar Jacobs.—An extensive paper in which the results obtained by Fittig, Hoogewerff, and others are critically examined. Among the products of the reaction are mesitol, oxy-mesitylenic acid, oxy-trimesinic acid, and oxy-uvitic acid. These compounds with a number of their derivatives are described at length.

Analysis of Organic Bodies Containing Halogens or Nitrogen.—Hugo Schiff.—The author describes with slight modifications the method proposed by Piria thirty years ago. The substance is weighed in a small platinum crucible, and in case of chlorine or bromine fills up with mixture of 1 part anhydrous carbonate of soda and 4·5 parts of lime, the whole being thoroughly mixed together by means of a platinum wire. The whole is then covered with a larger platinum crucible and the pair are inverted so that the bottom of the larger crucible is turned downwards. The space between the two crucibles is filled with the same mixture of lime and soda, the lid is put on, and the whole heated to redness over a strong Bunsen burner. The reaction is completed in about 10 minutes. In case of an iodine compound carbonate of soda is used without lime. The arrangements for the determination of nitrogen cannot be intelligibly described without the aid of the accompanying plate.

The Molecular Magnitude of Indigo.—Dr. E. v. Sommaruga.—The author finds the vapour-density of indigo = 9.45, and concludes that the formula for indigo must be $C_{16}H_{10}N_2O_2$ and not the half of these numbers.

Communications from the Laboratory of Applied Chemistry of the University of Erlangen.—These communications embrace the following papers:—Detection of Ethyl-diacetic Acid in Urine, by A. Hilger; on Solanin and its Decomposition Products, by A. Hilger; and, Certain New Salts of Uranyl, by Dr. R. Sendtner.

Influence of the Isomerism of the Alcohols and Acids on the Formation of Compound Ethers.—N. Menschutkin.—An important paper which does not admit of useful abstraction.

Contribution to a Knowledge of Polyporic Acid.—C. Stahlschmidt.—The author obtains hydropolyporic acid by treatment with caustic alkali, examines the salts of the new acid, obtains nitropolyporic acid by treating polyporic acid with concentrated nitric acid and certain chlorine compounds by the action of potassic chlorate and hydrochloric acid.

Contributions to a Knowledge of Ammoniacal Mercury Compounds.—H. Gerresheim.—An examination of Millon's base. The author announces an intention of shortly making known an application of this compound in water-analysis.

Moniteur Scientifique, Quasneville.
April, 1879.

Researches Conducted in the Laboratory of MM. P. Monnet and Co. at La Plaine.—P. Monnet, F. Reverdin, and E. Noelting.

Presence of Meta-nitro-toluol in Nitro-toluol.—The authors, in experimenting upon the acetylic derivative of a commercial toluoydin free from aniline, were led to suppose that in addition to the ortho- and para-derivatives it contained a little of the third isomer or meta-compound. To decide this question they have studied the nitro-toluol used in the manufacture of the toluoydin in question, and found their suspicions confirmed.

The Part of Meta-toluydin in the Manufacture of Aniline-Red.—The function of ortho- and of para-toluydin in the preparation of magenta has been studied by M. Rosenstiehl and other chemists; it seemed to the authors interesting to complete these observations by oxidising meta-toluydin either alone or mixed with aniline and the two other toluydins, especially as the presence of this base in a small extent had been traced in commercial toluoydin. They have heated various mixtures containing meta-toluydin with arsenic acid under the usual conditions for the manufacture of magenta and have extracted the colouring matter produced, and tested it by dyeing comparative samples:—

Base or Mixture of Bases in Equal Molecules.	Shade of the Product of Oxidation.
1. Aniline	Violet (violanilin).
2. Ortho-toluydin	Red.
3. Para-toluydin	Yellowish brown.
4. Meta-toluydin	Brown.
5. Aniline and ortho-toluydin	Red.
6. Aniline and para-toluydin	Red (para-rosanilin).
7. Aniline and meta-toluydin	Violet.
8. Aniline, ortho- and meta-toluydin	Yellowish and greyish red.
9. Aniline, para- and meta-toluydin	Red, slightly violet, and greyish.
10. Aniline, ortho- and para-toluydin	Red (ortho-para-rosanilin).
11. Ortho- and para-toluydin	Red.
12. Ortho- and meta-toluydin	Red, violet, and greyish.
13. Para- and meta-toluydin	Brown.
14. Ortho-, para-, and meta-toluydin	Red, violet, and greyish.

Artificial Alizarin.—C. Græbe and C. Liebermann.—The first part of this bulky treatise deals with the chemistry of artificial alizarin as understood down to 1874. Of the second part, which gives an account of subsequent improvements as far as the end of 1877, we shall shortly give an abridgment.

Contributions to the History of Benzol-green and Malachite-green.—This paper consists of certain memoirs by O. Dœbner and by O. and E. Fischer, taken from the *Berichte der Deutschen Chemischen Gesellschaft*.

Industrial Society of Mulhouse.—Proceedings of the Sessions of the Chemical Committee, December 11, 1878, and January 15, 1879.—Nothing is here described which has not been already noticed. The particulars of M. Kopp's process for the spectral analysis of dye-ware are not yet made known.

On Amber.—M. Helm.—Amber in entire fragments is permeable to water. It contains as much as 4 per cent of sulphur in the state of organic combination. This sulphur has probably been absorbed by the fossil resin in the state of hydrogen sulphide subsequent to its formation. The author describes another fossil resin, gedanite, which differs from amber by containing a smaller proportion of oxygen, and is softer, more fusible, and more soluble in ether. It is free from succinic acid.

Verhandlungen des Vereins zur Beförderung des Gewerbflusses. February, 1879.

The Manufacture of Magenta by Coupier's Process.—Dr. C. Häussermann.—The author remarks that Coupier's process has hitherto been adopted in but few establishments, and although the magenta thus produced is often preferred, especially as a raw material for the preparation of superior blues, it is not yet finally decided which of the two methods is preferable. For Coupier's process it is essential to use an aniline oil of sp. gr. 1.006 to 1.007 at 15°. It is converted into hydrochlorate with the presence of as little water as possible. To prevent the aniline hydrochlorate when dehydrated by a temperature of 140° from adhering too firmly to the sides of the vessel, two-thirds of the aniline to be used is slightly supersaturated with hydrochloric acid, concentrated till the temperature rises to 140°, and the remaining one-third of the aniline is then poured into the melted cooling mass. This operation is conducted in enamelled pans provided with a condensation apparatus. The mixture of aniline and aniline hydrochlorate is then introduced into the melting pans, adding to 100 parts of aniline about 50 parts of pure nitro-benzol, and by degrees 3 to 5 parts of iron filings.

March, 1879.

Ammonia Soda and the Production of Ammonia in Coke-burning.—Dr. Frank.—The author points out that the weak point of the Solvay process is its dependence on the supply and consequent price of ammoniacal salts. He insists upon the importance of utilising the volatile products—ammonia, tar, &c.—from coke works, which he considers would effect a revolution in all trades based upon the destructive distillation of coal.

Test for Mercurial Vapours.—At a recent meeting of the Society of the Physical and Natural Sciences of Bourdeaux M. Merget recommended paper steeped in the ammoniacal solution of nitrate of silver, or in chloride of palladium, as reagents for mercurial vapours much more sensitive than gold foil. This test-paper is very sensitive; a slip of sheet-copper plunged into a liquid containing 1 part of mercury in 10,000 remained bright after immersion, but if exposed to the ammoniacal nitrate of silver paper it occasioned a characteristic black spot. He finds that even when solidified mercury emits vapours in appreciable quantity.

MEETINGS FOR THE WEEK.

TO BE SOLD BY AUCTION pursuant to an Order of the High Court of Justice Chancery Division made in the Cause of Hutchinson v. Norwood 1878 H. No. 14 with the approbation of the Vice-Chancellor Sir Richard Malins the Judge to whose Court the Cause is attached by Mr. Thomas Colclough Leete (of the firm of Messrs. Branch and Leete) the person appointed by the said Judge at the Law Association Rooms Cooke Street Liverpool on Thursday the 29th day of May next at 3 o'clock in the afternoon.

The Valuable and Extensive Chemical Works situate at Widnes in the County of Lancaster known as Messrs. John Hutchinson and Co.'s No. 1 and 2 Works established by the late Mr. John Hutchinson and carried on by his executors since his death. The property comprises a superficial area of 71,385 square yards of land of which 16,859 square yards are freehold and 54,526 square yards are leasehold principally held for long terms of years at low ground rents 221½ square yards of the leasehold land have been sublet and chief rents amounting to £30 6s. 7d. will be included in the sale.

The situation of the works is exceptionally favourable for communication both by Railway and water they are divided by the St. Helen's Canal which affords a convenient means of access on peculiarly advantageous terms and they immediately adjoin the River Mersey fronting which there is a pierhead in connection with No. 2 Works where goods can be loaded and discharged free from toll.

The Works have Railway communication with each other and are also immediately connected by means of sidings with the London and North Western the Sheffield and Midland and Great Northern Railways and with the Widnes Dock in which as well as in the Canal there are rights of berthage connected with the works. They also possess ample facilities for drainage and for the disposal of alkali waste on favourable terms.

The buildings plant machinery and apparatus are on a very extensive scale the greater part being of the most approved construction they are now in first rate condition and are capable of producing weekly 500 tons of salt-cake 225 tons soda-ash 75 tons caustic soda 30 tons soda crystals 25 tons bicarbonate soda and 20 tons recovered sulphur for all of which productions these works bear a most favoured character in the market. There is also plant almost ready for working designed for the manufacture of about 50 tons per week of bleaching-powder by Deacon's process.

No. 1 Works consist of the necessary buildings machinery and plant for the manufacture of vitriol salt-cake soda-ash soda-crystals bicarbonate soda and sulphur with Smith's filters and joiner's workshops a well yielding weekly about 500,000 gallons Railway weighing machine Railway sidings and tramways throughout and loading and discharging berths on the Canal and Widnes Dock.

No. 2 Works consist of the necessary buildings machinery and plant for the manufacture of vitriol salt-cake soda-ash caustic soda bleaching-powder and sulphur with Offices and Lavatory Coach-house Stabling and Out-buildings Cooperage and Cooperage Store Locomotive Shed Smith's filters and joiner's workshops and railway wagon repairing shop railway weighing machine saw-mill mortar-mill and engine a well (weekly capacity 500,000 gallons) railways and tramways throughout and a pierhead and wharfage on the River Mersey.

The Works will be sold in One Lot as a Going Concern and the purchaser will be required to take the stock stores implements and utensils at a valuation.

The premises may be viewed on application to Major Cross at Widnes and particulars and conditions of sale may be had of Messrs. Gregory Rowcliffe and Rawle Solicitors 1 Bedford Row Messrs. G. S. and H. Brandon Solicitors 15 Essex Street Strand London of Messrs. Part Woodcock and Co. Solicitors Wigan and of Messrs. Branch and Leete Auctioneers Hanover Street Liverpool.

SOAPERY.—To be Let, on advantageous terms, the ALBERT SOAP-WORKS, Sheffield; the only Soapery situated in the midst of a very large and increasing population. It contains five pans—one to cleanse 9 tons, two 6 tons, one 4 tons, and one 3 tons; Ley Vats; Hot Room; Steam-Engine; Circular-saw Room; and all suitable apparatus. Tenant may enter on very favourable terms, and at a moderate rental.—May be seen working at any time, by applying at 69, Broad Street, Sheffield.

A Chemist, trained at Royal School of Mines, with Eight Years' practical experience, desires an Engagement. Excellent references.—Apply F. L. C., CHEMICAL NEWS Office Boy Court, Ludgate Hill, London, E.C.

A German Chemist (Ph.D.), holding Diplomas from University and Polytechnicum, who has already had experience in a Manufactory, seeks a Situation in a Chemical Manufactory in England. Good references.—Address, K. D., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Advertiser, with Six Years' Experience in Analytical Chemistry, desires an Engagement as Assistant or as Chemist in Works. No objection to go abroad.—Apply, H. H., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted an Intelligent Workman who thoroughly understands the manufacture of Acetic Acid and other Wood-products.—Apply to "Wood," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

FOR SALE.

A Quantity of Kelp at a Low Price.—For samples, &c., address JOHN G. HARVEY, 31, Old George's Street, Cork.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and Co., Clayton, near Manchester.

SULPHO-CYANIDE of LIME.—A Supply of this article wanted.—Apply to B 18, CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

IMPORTANT TO SU PHURIC ACID MANUFACTURERS. NORRINGTON'S PATENT.

In the ordinary method of Manufacture, at the time of charging the Kilns, a considerable escape of gases takes place. This is attended with proportionate loss of Sulphur, and with much inconvenience to the workmen, as well as annoyance to the vicinity of the Works. This may be entirely avoided by the adoption of C. Norrington's patented invention, which can be applied at moderate cost to existing Plant, as well as in the erection of new Works. It may be seen in full operation on extensive Plant at Messrs. C. Norrington and Co.'s Chemical and Manure Works, Cattedown, Plymouth, where the fullest information may be obtained, with terms for license.

MINERALOGY AND GEOLOGY.

NEW LIST of Collections of Minerals, Fossils, and Rocks, with prices. New List of Minerals for Chemical Purposes, Manufactures, and Research. New List of Varieties of Rocks. New List of Prices and Sizes of Cabinets for Natural History and other purposes. New Catalogue of Secondhand and New Books on Geology and Kindred Sciences. New Supplementary List of Books. THE CHEMICAL NEWS.

VOL. XXXIX. No. 1018.

ON ELECTRIC DISCHARGES IN ATTENUATED GASES, AND ON CERTAIN PHENOMENA IN GEISSLER'S TUBES.*

By H. EUGEN GOLDSTEIN.

IN H. Goldstein's memoir, communicated to the Berlin Royal Academy of Sciences, May 4, 1876, we find the following results:—

The existence of a twofold conduction in attenuated gases, hitherto assumed, and corresponding to the so-called positive and negative light, cannot be retained. With the exception of the peculiar stratification of the negative (cathodic) light the author has succeeded in imparting all its supposed distinctive properties to the positive light.

If the calibre of the tube widens in the direction of the current, the discharge appears as a positive light. Under reversed conditions it is negative. In a number of experiments the cathodic discharge behaves as if taking place through a number of fine pores. By means of great rarefaction or, by increasing the intensity of the discharge, H. Goldstein succeeded in converting the spectrum of the positive light in tubes filled with air, nitrogen, or hydrogen into a spectrum of the cathode light. The phenomena observed by Reitlinger and Kuhn (*Pogg. Ann.*, 141) are explained by the fact that these experimentalists made use of a tube whose gaseous contents were absorbed by the electrodes during the passage of the current. The author has repeatedly met with such tubes. Under the influence of a magnet positive light behaves exactly like the negative, and is even affected by a smaller magnetic force. If the anode is in an axial position it is surrounded by a luminous cylinder, which again is separated by a dark space from the metallic surface. The form which the electric light of the total discharge assumes under the influence of the magnet depends on the quantity of electricity passing at once. The author has specially examined the green light which appears in tubes of common glass at certain degrees of pressure and intensity of the discharge. The luminosity of the sides of the tube is not a phenomenon of fluorescence but of phosphorescence, and can change from green to orange.

§11. The cathodic light which produces this phosphorescence is, as was already assumed by Hittorf, a rectilinear radiation, which extends from the cathode into surrounding space. Still there are essential differences between the diffusion of this remarkable motion and the likewise rectilinear movement of the light, some of which differences are here brought forward.

Hittorf observed that a body placed between the side of the glass and a point-like cathode, throws a shadow in the phosphorescent light of the latter.

Well defined, though not very sharp shadows of small objects, may be obtained not merely from a point-like or linear cathode, but also from extended negative surfaces placed at a small distance from the opaque object.

A surface which merely radiates light, *e.g.*, an ignited body, under similar conditions throws a scarcely visible expanded penumbra.

* The Editor takes the earliest opportunity of bringing before his readers a notice of certain researches due to H. Eugen Goldstein which have hitherto escaped his notice, and which, to a certain extent, anticipate some of the results announced in his papers, "On the Illumination of Lines of Molecular Pressure," read before the Royal Society, December 5, 1878, and "Contributions to Molecular Physics in High Vacuum," read before the Royal Society, April 3, 1879.

The negative light is therefore a rectilinear radiation, which is propagated preferably in a manner almost normal to the producing surface.

§12. Suppose the density of the gas and the intensity of the current in a Geissler's tube so regulated that the side of the tube shows a phosphorescent light round the cathode.

If we introduce along side of and parallel to the cathode a wire not connected with any source of electricity, according to what has preceded, the luminous wire will throw a narrow sharply-defined shadow of the non-luminous wire. As soon, however, as both wires are connected together, and thus converted into cathodes, we perceive on the side of the tube, in the middle of the light-green light, two large, dark, sharply-defined surfaces, which are bisected by a plane passing through both wires. If the wires are straight and not too short their form is oblong, with the longer sides parallel to the wires.

The explanation of these phenomena is:—

The negative electrode is the seat of a repulsive force, which causes every discharge-ray passing near the cathode to turn away.

The figures of the phosphorescent light produced by the cathode-rays are determined by the form of the negative surface. The head of a coin used as a cathode is reproduced in this manner with the accuracy of a portrait in the phosphorescence on the glass.

The author has also studied the stratification of the light. This phenomenon, as regards the positive light, appears in a continuous series of forms, whose ultimate members have little resemblance. The brightness of the successive strata is neither equal nor symmetrical in the direction of the discharge. Each stratum has its maximum brightness near its negative border. Different portions of one and the same stratum differ also in colour.

If we call the "ordinal number" of a stratum the number which shows its successive place, counting from the negative light, the character of every stratum may be pronounced a function of its ordinal number. In all gases the stratification is sharper and more distinct the nearer we approach the negative end of the positive light. This proposition applies not merely to any gas, but to tubes of any, and even compound, form. If we divide a cylinder into a section for the cathode, and into several other sections communicating only by narrow apertures, we find that each stratum of each section has in each other section a stratum corresponding to it in colour, brightness, &c., namely, the stratum having an equal ordinal number. Each single stratum of positive light is an image corresponding to the formerly so-called negative or cathodic light, and the stratified positive light consists of a succession of complexes of negative light.

From the demonstrated identity of positive and negative light, and from the transformation of a negative "bush" into a single positive stratum, we are inversely entitled to regard every complex of negative light essentially as a stratum of positive light.

The boundary of the positive light is independent of the position of the positive pole, and also of the length of the whole discharge.

A displacement of the negative pole in the direction of the discharge effects a displacement of all the positive strata in the same direction. Tubes can be constructed which contain no positive light. With decreasing density all the strata are moved towards the positive pole, while their number decreases.

In a second memoir presented to the Berlin Academy by H. Goldstein, November 23, 1876, the author finds that a portion of the side of the tube, touched internally by a conductor, behaves exactly like a cathode, and emits light possessing all the properties of the cathodic light. The phenomena observed by H. H. Reitlinger and V. Urbanitzky, *i.e.*, a green light opposite a conductor approximated to the tube, are hence merely the excitements which the cathodic rays proceeding from the point of contact must occasion as soon as they, in highly rarefied

gases, extend to the opposite side of the tube. Hittorf has made known in what manner a magnet acts upon the rays of cathodic light. If the results which he has established are applied to the movements of the rays of negative light, there follow, as necessary consequences, all the movements which are observed in the green light under the influence of the magnet. The form of the luminous surface is quite independent of the form of the side touched by a conductor. It can be directly shown with gas-densities somewhat greater than correspond to the production of the green light that the spot touched by the conductor emits a cathodic light. Over the spot in question are seen spheroidal tufts of blue light. The luminous green surface is merely the basis of these blue rays. The author has shown that the positive and negative light can perfectly interpenetrate each other for spaces of any length.

The intensity of the green light emitted from a point of the side of the tube, if the intensity of the exciting radiation is constant, decreases with the continuance of the excitement. This decrease is the greater the stronger the intensity of the exciting rays and the original brightness of the luminous point.

"If between the cathode and the green luminous side of the tube there is introduced a solid body, its shadow is thrown upon the side, since it excludes such rays of the cathode as impinge upon it from reaching the side. If the solid body after some time is removed, the shadow disappears, but an image of the body remains, distinguished from the surrounding luminous surface by its greater brightness, and exactly reproducing the shape of the former shadow."

LOSS OF NITRE IN THE VITRIOL MANUFACTURE.

By JAMES MACTEAR.

THE letters which have been published in recent issues of the CHEMICAL NEWS have thrown considerable light on the above subject, but much still remains uncertain. It seems to me that it is the duty of those who have studied this subject to make public whatever facts they may have ascertained, so that sound conclusions may ultimately be drawn from a careful comparison and consideration of these facts. With this view I beg indulgence and space for some details of the work I myself have done in this direction, and trust it may also induce others to publish the result of their researches.

Shortly speaking, the losses in the case of good plant might be stated as occurring in two ways:—

1. As lost by escaping with the exit gases into the atmosphere.
2. As lost in the acid in the chambers for use (which may or may not have passed through Glovers).

If, however, the amount of nitrous compounds in the escaping gases capable of absorption by caustic soda, and the amount of nitrous compounds in the acid used, be estimated, it will be found that these two sources of loss are very far from accounting for the amount used.

In my researches the estimation of the nitrous compounds in the escaping gases was made by taking average samples over twenty-four hours, the aspiration being at a constant rate (a very necessary precaution); and the determining the nitrogen present in the absorbing solution by means of the zinc and iron distillation with caustic soda process—which I showed in a paper read before the Newcastle-on-Tyne Chemical Society, January 24th, 1878—gives most accurate results when properly carried out.

These daily average samples were checked by an average for the week, and only in very rare cases was there an appreciable difference from the average of the daily tests.

The amount of work involved in these experiments is

very great, but in my opinion it is only possible to arrive at just conclusions by a long series of such tests. The arrangement of these results weekly was as follows:—

Week ending 187

pyrites used.

nitre "

O. V. "

arg. oxygen in exit gases.

" grains NaNO_3 per cubic foot.

vol. per cent NaNO_3 in acid used.

calculated as NaNO_3 on $100\text{H}_2\text{SO}_4$.

NaNO_3 lost.	Tons.	Per cent.	On 100 Sulphur.
In acid used ..	0.228	5.36	0.170
" exit gases ..	0.783	18.36	0.582
As unaccounted for	3.247	76.28	2.418
Total ..	4.258	100.00	3.170

The figures obtained are embodied in the following table, and represent the results of seven series of large chambers, all worked with Gay-Lussac towers, and all but one with Glover towers, the one exception denitrating its acid by hot water in a long tunnel. (See Table on next page.)

It will be seen that the unaccounted for loss has never been under 50 per cent of the nitre used, and in one case has reached 90 per cent, which is not explained by the percentage of nitre used on sulphur, as we have—

Week No. 13, 52.6 per cent of nitre = 2.683 on sulphur.

" No. 23, 90.43 " " = 3.831 "

The total nitre used being—

Week No. 13, 5.10

" No. 23, 4.236.

It would seem that the unaccounted for loss is intimately connected with the working of the chambers, as in most cases it is found that where the percentage of nitre used on sulphur is high, so also is the loss of nitre unaccounted for calculated on sulphur.

As yet no one seems to have hit the blot—Where does the loss take place, and under what conditions? Did we know this we should be able to manufacture our acid at a much reduced cost, were we able to avoid this unaccounted for loss, which is at least 2 to 3 per cent on the sulphur.

The directions in which I have looked for a solution of the problem are—

- A. Decomposition of the nitrous gases in contact with hot kiln gas before entering the Glover towers or chambers.
- B. In their passage through the Glover tower.
- C. In their passage through the series of condensing apparatus generally known as vitriol chambers.

Hitherto my results have been much more of a negative character than otherwise; but a record of failures is of great use, and often leads to a right way out of a difficulty.

I made a number of experiments on a series of vitriol chambers which had no Glover tower, and where during the continuance of the experiments all the nitre was potted in a large pot placed at the end of the row of kilns, all the sulphurous gas passing over it.

The data used in calculating out these experiments in No. 6 series of chambers were—

No. of experiment	hours.
tons pyrites =	sulphur.
lbs. NaNO_3 =	per cent on sulphur.
per cent oxygen in exit gas from Gay-Lussac.	
grains NaNO_3 per cubic foot in inlet gas to Gay-Lussac.	
cubic feet of exit gas calculated from oxygen.	
grains NaNO_3 per cubic foot calculated.	
" " actually found.	
unaccounted for or loss.	
= per cent of NaNO_3 charged =	per cent on sulphur.

LOSSES OF NITRE.

The following are the results obtained:—

Loss of Nitre in No. 6 Chambers, working large pot (A).

1st expt., 24 hours, 31 per cent of nitre used.
2nd " 60 " 43 " "
3rd " 53 " 68 " "
4th " 43 " 68 " "

Actual average of 7½ days, 60.4 per cent of nitre used.

The average NaNO₃ used during this time was 9 per cent on sulphur and 60.4 per cent of total, or 5.44 per cent on sulphur has disappeared.

During the same time the gases entering Gay-Lussac contained on an average 3.71 grains NaNO₃ per cubic foot, while the amount in the exit gas was 0.30 grain, which shows an absorption of 92 per cent. The gases entering Gay-Lussac were aspirated at a regular continuous rate of 0.5 cubic foot per hour. The pyrites was charged at the rate of 8 cwts. per hour, and the nitre charged varied from 30 to 40 lbs. per hour.

The method of working was now changed, small pots being used for the decomposition of the nitre, and these were placed actually on the burning mass of pyrites in the kilns. The following are the results:—

Loss of Nitre in No. 6 Chambers, working small pots (B).

1st expt., 48 hours, 45.3 per cent of nitre used.
2nd " 48 " 55.4 " " "
3rd " 48 " 42.6 " " "
4th " 24 " 53.7 " " "

Actual average of 7 days 48.6 " " "

Average NaNO₃ used during above time 11.6 on 100 sulphur, 48.6 per cent of which has disappeared, or 5.63 per cent on sulphur.

The gases entering Gay-Lussac contained on an average 4.85 grains NaNO₃, and the amount leaving was 0.058 grain, showing an absorption of 98.8 per cent.

It would appear, then, that as far as these experiments go we have lost in the case where the nitre was decomposed in the large pot in the colder portion of the flue 5.44 parts of nitre for 100 of sulphur, and in the case where the nitre was decomposed in the small pots in the

kilns where the heat was highest 5.63 parts. The difference, 0.23 part, is very small and is not more than the error which might be expected in such experiments, so that in this case I do not think we have proof of a greater loss of nitre by the decomposition of the nitre at a higher temperature, at least not to the extent that might be expected.

On the other hand, there has been required to keep the chambers in as nearly as possible the same condition, in the case of—

Large pot	9.0 per cent of nitre
Small "	11.6 " "

The fact that when using small pots in the part of the flues or in the kilns that more nitre is used is one that is quite beyond doubt and well known to all experienced vitriol manufacturers. It seems to me to depend somewhat on the fact that at the high temperatures the nitrous compounds are driven off much more rapidly, and sent into the chambers, as it were, in "whiffs" or "guats" instead of in an equally distributed manner; it is more difficult to keep the chambers in good condition, and the amount of nitre used is therefore increased.

If we assume that the absorption in the Gay-Lussac be equal in both cases to, say, 95 per cent of the nitrous compounds entering, then the two cases above detailed would show:—

A. 9.0 per cent nitre used—5.44 lost=3.56 entering tower.
B. 11.6 " " "—5.63 " " " =5.97 " "

The loss in exit gases would then be—

A. 0.178 per cent on sulphur.
B. 0.298 " " "

And if we take the exit loss in "A" as 100, the loss in "B" would be 167, or the loss by the method of working as in "B" required 67 per cent more nitre than that in "A," which is sufficiently convincing as to the inadvisability upon this system.

The above experiments, although numerous and interesting, are by no means complete, and more light is greatly wanted.

It is pretty clear that there is a very large loss between the Burners and the Gay-Lussac towers; the experiments in No. 6 series of chambers show that the loss was not very greatly increased by the greater heat at which the nitre was decomposed, and at which consequently the nitrous compounds and sulphurous acid began to react upon each other. We are thus shut up to admit a large loss or reduction of nitrous compounds in the chambers themselves, or no doubt where Glover towers are in use, in the Glovers and chambers combined. So far as my results go there is no proof that the loss is greater where Glover towers are in use; it is, in fact, more the other way, for while the loss where no Glover is used amounts to in—

Case A, 5.44 per cent NaNO_3 on sulphur,

" B, 5.63 " " "

the whole series of experiments extending over more than a year of weekly testings, the loss when Glovers are used is not more than about 3.5 per cent on sulphur. My own opinion is that the greater regularity with which the nitrous compounds are supplied to the chambers has a great deal to do with the question of loss; but this is a point not yet worked out, so far as I am aware, by any one.

The varying statements that one hears made are so contradictory that it were well that those who have trustworthy experiments should publish them, so that by a careful digest and comparison we might come to some valid conclusion. As for myself, I may say that at present I am halting between two opinions, but I trust that experiments now in progress may enable me to decide either for one or the other.

Mr. Davis, in his letter in the *CHEMICAL NEWS*, vol. xxxix., p. 216, refers to the escape of nitric oxide and invites chemists to state their views, after which he will give the experiments which he has made on the subject. As a chemist who has failed completely in obtaining reliable means of determining the amount (if any) of nitric oxide in exit gases, permit me to appeal to Mr. Davis as to whether he should not give us these results at once. As one of the Alkali Act Inspectors, Mr. Davis ought I think to give us any information which may enable us to keep down the escape of noxious vapours, to say nothing of the economy of nitre.

I notice from the correspondence generally that the amount of nitrous compounds present in the actual acid run off for use is not well known. It varies a good deal, but the tests in the table show what it has been in my own case, and the following gives details of a number of tests of the works of my firm at Newcastle:—

Week No.	Vol.	p.c. NaNO_3	in acid	Per cent of Nitre used.

St. Rollox, May 20, 1879.

Experiments on Alpine Dairy Farming.—Dr. W. Engling and Dr. v. Klenze.—The vaunted alpine milk differs from other good milk merely by a high percentage of milk-sugar and by the aroma derived from certain odoriferous plants. The influence of manured pastures as compared with unmanured has not been satisfactorily determined, and the authors purpose renewing their experiments. Butter seems to remain free from rancidity the longer the freer the air from ozone.—*Biedermann's Central-blatt.*

ON THE INFLUENCE OF VARIATIONS OF TEMPERATURE ON THE DEVIATION OF POLARISED LIGHT BY SOLUTIONS OF INVERTED SUGAR.*

By P. CASAMAJOR.

(Concluded from p. 214.)

THE announcement that it was at 92° that d became equal to 0, led me to think, that, possibly, the law that I had deduced from Clerget's table was not correct. It is true that the temperatures given by Clerget only extend from 10° to 35°C. , but, between these limits the law which governs the deviations of inverted sugar as affected by temperature, as deduced from his table, is represented by a right line. This I considered as an important fact, because I do not remember a single instance in which a law is expressed by a rigorous right line, between limits that are sufficiently distant, in which this right line is not continued throughout. Having, then, very serious doubts about the accuracy of Clerget's table, I started to discover what the true law was.

For this purpose I prepared pure sugar, by taking the best cut loaf sugar and soaking it in 95 per cent. alcohol for several hours, taking the sugar out, letting the pieces drain, and drying them by hot air.

This sugar, tested before inversion, gave exactly 100 by the saccharometer. The solution, after the direct test, was inverted and tried again in the saccharometer at several degrees of temperature. After making a great many tests at various temperatures, I was forced to the conclusion that not only is Clerget's table correct for temperatures between 10° and 35°C. , but that the law represented by—

$$d = -44 + \frac{t}{2}$$

held good even beyond 88°C. , at which temperature the deviation is equal to 0.

To enable an observer to seize at a glance the results I have obtained, I took a large sheet of cross-section paper divided very accurately into inches and tenths of an inch. On the line of the abscissas I took for every degree Centigrade a space equal to two-tenths of an inch, and, on the line of the ordinates, I took for every division on the negative scale of the saccharometer, four-tenths of an inch. I then drew a right line, connecting the point representing -44 of the saccharometer scale with the point representing 88°C. This right line represents the law expressed by the formula—

$$d = -44 + \frac{t}{2}$$

Afterwards I plotted on this sheet 68 observations made at temperatures varying from 14° to 92°C. The result of this operation was that, out of 68 dots, 10 were entirely erratic, 18 were exactly on the line, and the remaining dots were so close that their distance from the line could be explained by an error of $\frac{1}{4}$ of a division in the observation of the saccharometer. In explanation of these results, I may state that the dots which I have called erratic were due to observations made on turbid solutions, or while the temperature was fluctuating. Observations made under such circumstances cannot be expected to be accurate. The other observations were made under conditions infinitely more trying to the eyes than those under which ordinary saccharometric tests are made. When the temperature fluctuates in the least during an observation, the disk of double quartz becomes distinctly elliptical, and, at times, the line of separation between the two quartz plates swerves alternately to the right and to the left.†

* Read before the American Chemical Society, Feb. 6th, 1879.

† The sheet on which these dots are plotted was shown to the American Chemical Society. I have not thought it necessary to have it engraved, as the explanation given in the text makes the subject sufficiently clear.

To obtain the different temperatures required for these experiments, I had to alter a saccharometer so as to interpose a water-bath between the two optical portions in a manner similar to that adopted by Dr. Ricketts. At the bottom of this water-bath is an opening, communicating with the interior of a closed tube, three inches long, projecting at a right angle. To the closed end of this tube a Bunsen burner was applied when the water-bath was to be heated. In this water-bath I placed the tube containing the solution of inverted sugar. This tube is made of thin brass, and is closed at each end by a glass plate, held by a screw cap in the ordinary way. In the middle of this tube a portion was cut off, two inches long, and as wide as the diameter of the tube. Over the opening thus formed was soldered a projection, as shown in figures 1 and 2 at A. At first I used a tube with a cylindrical projection, of the same diameter as the tube itself, for the introduction of a thermometer to ascertain the temperature of the liquid in the tube, in the manner adopted for Clerget's thick glass tube. I think that the plan represented in fig. 1 and fig. 2 is preferable, as it allows the operator to agitate the solution by moving the thermometer backwards and forwards in the tube. A great advantage obtained by having a projection of this shape is that the

the tube was different from that of the water bath, and that the difference between the two temperatures must depend on the rate of heating the water-bath, *i.e.*, on the size of the flame.

I have mentioned that a thermometer with a long bulb may be the cause of serious errors; so may a thermometer whose movements are too sluggish. In the thermometer that I have used, the bulb was very short; the mercury column was very fine, so as to respond very quickly to slight variations of temperature. These thermometers have 40° C. on a scale six inches long. One goes from 0, to 40°, the next from 30° to 70°, and the third from 60° to 100°. Particular attention was paid in these experiments to keeping the water-bath in continued agitation immediately before taking an optical observation, and while the observation was being made. The thermometer in the brass tube was also kept moving backwards and forwards for some time before looking through the tube. Unless these things are done, there is no certainty that the temperature observed is that of the liquid in the tube.

If, as I am convinced in this case, from the numerous experiments I have made, observations on solutions of inverted sugar, taken at any temperature, are as reliable as those made at any other temperature, there can be no

FIG. 1

FIG. 2

liquid in the projection does not rise or fall perceptibly when the thermometer is taken in or out. If the vertical projection has a small section, whenever a thermometer is placed in it the liquid rises in this projection, and a portion may be high enough to stand above the level of the water bath. Under these circumstances, this portion of the liquid gets cooler than the portion in the horizontal tube, and, if the bulb of the thermometer is longer than the diameter of the horizontal tube, the temperature indicated will be too low. Too much care cannot be taken in observing these minutiae, as otherwise accurate results cannot be obtained. Even with the greatest care, it is impossible to avoid errors in the observation of solutions whose temperature does not remain constant. In this connection I may be allowed to express the opinion that it was due to the want of a tube like the one represented in fig. 1 and fig. 2 that Dr. Ricketts was led to take 92° as the temperature at which d becomes equal to 0. I have repeatedly found at 92° that the deviation is on the positive side of the scale, ranging from 1.4 to 2, according as the observation was more or less accurately made. In his experiments, Dr. Ricketts did not take the temperature of the liquid in his tube, but that of his water-bath. As his tube was made of glass, about one-eighth of an inch thick, we must suppose that temperature of the liquid in

utility in heating the solution by the interposition of a water-bath. Taking observations at the temperature at which the deviation is equal to 0, merely saves the trouble of dividing—

$$D - d \text{ by } 144 - \frac{t}{2},$$

and it is not certainly worth while to go out of our way for this purpose. The most convenient plan for making observations on solutions of inverted sugar is to follow the directions of Clerget, which are the following:—

A sugar solution is placed in the ordinary way in the saccharometer, and the saccharometric test, D , is noted down. To a portion of this solution, say 50 c.c., are added 5 c.c. of concentrated hydrochloric acid. These are mixed by shaking up the graduated flask, and the flask is placed in a water-bath and heated to 68° C., taking about 10 minutes in raising the temperature. This solution is afterwards immediately cooled to a temperature between 10° and 35° C. We then placed it in a thick glass tube, provided with a vertical tubulure for the insertion of a thermometer to show the temperature of the liquid at the moment of observation. This tube is made 22 centimetres long, instead of 20 centimetres, so as to compensate for the addition of one-tenth of hydrochloric acid. If th

temperature, at the time of observation, is t , and the deviation to the negative side is d , we take the algebraic difference of the two readings, $D-d$, which is the arithmetical sum. To find the correct quantity of cane sugar C , from these observations, we must remember that for 100 per cent. of sugar,—

$$D-d = 144 - \frac{t}{2},$$

therefore,—

$$\frac{C}{D-d} = \frac{100}{144 - \frac{t}{2}} \text{ and } C = \frac{(D-d) \times 100}{144 - \frac{t}{2}}.$$

If we have Clerget's table, we may, instead of making this calculation, follow the practical directions at the head of the table.

Instead of inverting by heating to 68° C., and then cooling down rapidly, it is advised by some authors that the solution be maintained at 70° for at least 15 minutes. I can say, after doing both things repeatedly, that, in the second case, the solution is no better inverted than in the first. Some persons think it necessary to heat at 70° for an hour. This I did not try, as I had found no advantage in heating 20 minutes longer than Clerget directs.

For solutions that are to be heated above 68° for experimental purposes, it is necessary to neutralise the hydrochloric acid by a base, as otherwise the solution becomes very red. For this purpose the preference should be given to carbonate of soda, which gives the best results. I put enough of carbonate of soda to make the solution slightly alkaline, and afterwards make it acid with a slight excess of acetic acid. In this condition the solution may very conveniently be placed in a brass tube. For some reason which I have not been able to discover, when the hydrochloric used in inversion is neutralised by magnesia, the indications of the saccharometer are always too low.

When Venteke's saccharometer is used for testing inverted sugar we are obliged to operate on solutions of greater dilution than the normal solution containing 26.048 grs. of sugar for 100 c.c., because the negative side of the scale is very limited, reaching only to -16 on some instruments. A solution holding 26.048 grs. of sugar in 100 c.c. is tested directly. Then 50 c.c. of this are transferred to the beaker; the 50 c.c. flask is washed out, and the wash water is added to contents of beaker, and also 10 c.c. of hydrochloric acid. After the solution has been inverted and saturated with carbonate of soda, if necessary, the whole is put in a 100 c.c. flask, and enough water is added so that the whole solution at 15° C. shall occupy 100 c.c. The result of the test, after inversion, has then to be multiplied by 2.

I will conclude by giving from my books a series, 28 consecutive tests of raw and refined sugars. In the second column I give the direct test, before inversion; in the third column, the correct test, as afforded by inversion. In a fourth column I have given the copper test for glucose, when I happened to have it. These glucose tests show that the substances which reduce the alkaline tartrate of copper are, for the most part, without action on polarised light.

* Since this paper was read before the American Chemical Society, Dr. Behr has kindly called my attention to a paper of Dr. Tuchschnid in Scheibler's *Zeitschrift* for 1870, p. 649. After a series of elaborate experiments, Dr. Tuchschnid concluded that Clerget's table was very reliable. He investigated the law of this table between 4° and 41.8° C. Instead of the formula given above, he found—

$$R = \frac{100 S}{144.16035 - 0.50578 T}; \quad R \text{ corresponds to } C, S \text{ to } D-d.$$

This formula leads to 87.3° C. as the temperature at which the deviation becomes 0. The law of $d = -44.16035 + 0.50578 T$ is also represented by a right line. As to the results given by this formula, as compared with the one I have given, they may be judged by the following:—

Degrees C.	Tuchschnid.	Clerget.
10°	139.1	139
25°	131.747	131.5
35°	125.458	126.5
4°	123.875	124

Designation of Sugar.	Saccharometric Test (before Inversion).	Corrected by Inversion.	Glucose, Copper Test.
Raw	86½	87	
"	85	86	
Refined—B	91½	92	
" —C	83	83	
Raw	77	80	
"	90½	90½	
"	91	90½	3.57
"	80	84	11.5
"	84	86½	
"	84	89	
"	75½	79	
"	79	81	
"	90	90	4.30
"	95	94½	
Refined	78	78	8.2
"	81	82	7
Raw	92	92	2.5
"	91	91	2.5
"	87	88	5
"	90½	91	2.5
"	88	87	
Manilla	82	81	7.25
"	84	82	7.92
"	83½	81	7.5
Melado	73½	74	7.5
Domestic	82½	81½	
"	85	86	
"	78½	76½	

In the case in which the test before inversion is lower than when corrected after inversion, the presence of an excess of lævo-rotatory substance is indicated. When, on the contrary, the test, before inversion, is higher than after inversion, as in the case of the Manilla sugar, an excess of dextro-rotatory substance is indicated. If these sugars are inverted, and the solutions of inverted sugar are tested in the saccharometer at 85° C., they would show deviations on the positive side of the scale. This, however, does not enable us to decide to what particular dextro-rotatory substance the deviation is due.

COMPOSITION OF A BOILER INCRUSTATION

By ALFRED SMETHAM, F.C.S., A.I.C.

ON analysing a boiler incrustation which was lately submitted to me for examination I found it, after drying at 100° C., to have the following somewhat unusual composition:—

Oxide of iron..	24.72
Oxide of lead ..	8.41
Oxide of zinc..	44.39
Lime ..	0.99
Magnesia ..	0.77
Sulphuric acid ..	1.22
Carbonic acid ..	3.34
Insoluble matter in aqua regia..	5.60
Water of combination, organic matter, and undetermined ..	10.56

100.00

Before committing myself to an opinion as to its cause, I wrote to my clients asking them for particulars of construction of the boiler, and learnt in answer that it was a "hot-water circulating boiler for domestic use," and, further, that the boiler and cylinder were constructed of "galvanised" iron, and communicated the one with the other by means of leaden pipes.

The explanation which I gave of the cause was briefly this:—The town water, with which the boiler was fed, and which is soft to commence with, would, on boiling, be rendered still softer, and by constantly circulating

through the leaden pipes would dissolve a small quantity of the lead. This, passing either into the cylinder or boiler, would be reduced to the metallic state by the zinc with which the iron is "galvanised," and a voltaic action would be induced, the zinc acting as the positive and the lead as the negative metal. By this means a rapid and increasing action would be set up, which after dissolving the zinc would act upon the iron in precisely the same way as the bottom of iron railings, fixed into stone by means of lead, are corroded at their lower ends.

It is thus easy to see how the deposit, which was of a foxy-brown colour and friable, would soon be formed, and the small amount of lime and magnesia salts which are mixed with it prove that the action must have been rapid.

If, as seems probable, there was any metallic lead in the deposit when first removed, this had become oxidised by exposure to the air, to which it was exposed for some time previous to analysis. From a rough sketch of the boiler and fittings which I received, it seems probable that the lead pipes were in metallic communication with the galvanised iron, and if so a much more general action, as well as the local one before indicated, would take place, and destruction would occur at a proportionately greater rate.

CORRESPONDENCE.

ENAMELLED IRON COOKING-VESSELS.

To the Editor of the Chemical News.

SIR,—I had an opportunity some weeks ago to examine several enamelled iron cooking-pans which were submitted to my approval. By heating the pans two hours on a water-bath, with diluted (7 to 8 per cent) acetic acid and some common salt, and by analysing the solution thus obtained, I found a considerable quantity of oxide of zinc; and as the combinations of zinc are considered to be very injurious to health, and sauces, &c., very often contain mixtures of salt and vinegar, I think it useful to call the public attention to this examination. A family here of seven persons were poisoned by using these pans. The pans were of German and Belgian origin.—I am, &c.,

P. F. VAN HAMEL-ROOS.

Analytical Laboratory, City of Amsterdam,
May 19, 1879.

THE VITRIOL MANUFACTURE.

To the Editor of the Chemical News.

SIR,—Permit me a few lines to point out an error which has crept into Mr. Davis's calculations (CHEMICAL NEWS, vol. xxxix., p. 216).

The error consists in Mr. Davis applying my 20 per cent allowance for chambers working with Gay-Lussac to a system having no such apparatus. When I assumed the loss at 20 per cent I did so fully alive to the fact that the introduction of the Gay-Lussac causes a difference not in the absolute quantity of nitre destroyed per 100 of sulphur, but in the relative quantity, as expressed on the nitre used. In works without Gay-Lussac tower the working nitre and the nitre used are the same quantity, and the loss expressed as percentage on either is identically the same. But in works with Gay-Lussac the working nitre is double and more of the nitre used; hence the same absolute loss will yield in this case two different ratios, depending upon the unit chosen being either the working nitre or the nitre used,—i.e., added to cover losses. When I used the latter quantity as unit for comparison, and admitted 20 per cent of loss in chambers working

with Gay-Lussac, it was equivalent to an admission of a loss of from 5 to 10 per cent in chambers not connected with Gay-Lussac columns.

Thus Mr. Davis's figures would, when in strict accordance with my statement, be as follows:—

	Cwts.
Nitre used	16.0
20 per cent decomposed in chambers, or	
5.3 per cent on the 60 cwts.	3.2
10 per cent loss with exit gas	1.6
10 per cent loss with vitriol	1.6
5 per cent leakage	0.8
Total loss accounted for	7.2
„ not accounted for	8.8

Mr. Davis's own calculation would be more in accordance with Dr. Lunge's statement, since he puts the loss in systems connected with Gay-Lussac towers at 12 cwts. out of 16 cwts. used = 75 per cent of the nitre used.—I am, &c.,

FERDINAND HURTER.

Laboratory, Gaskell, Deacon, and Co.
Widnes, May, 1879.

THE VITRIOL MANUFACTURE.

To the Editor of the Chemical News.

SIR,—Against my wish I must again trouble you, but I hope for the last time on the present question, to afford me some space for replying to Dr. Hurter's and Mr. Davis's letters (CHEMICAL NEWS, vol. xxxix., pp. 215 and 216). So far as the question is concerned in which I took up my pen before, a reply would not be called for; for Dr. Hurter adduces no proof of an appreciable loss of nitre in the Glover tower, merely stating that "he has many reasons for thinking so." I am content to leave that question where it stands, and I refer again to my former letter and to our lengthy discussion in the pages of *Dingler's Journal*. I do not think that there is any inconsistency between my opinion as stated before and that expressed in my treatise, viz., "that certainly the Glover tower is in this respect no worse than any other denitrator," for hitherto, as far as I know, nobody has contended that in the steam columns, &c., any loss of nitrogen takes place by reduction to N_2O or N . Since then, in a paper about to be published, I have proved that denitration by hot water or steam is insufficient when the nitrous vitriol, by faulty work, contains nitric acid.

As I do not wish to extend this letter to an undue length I refrain from going into some fresh matters raised in Dr. Hurter's letter, which are only slightly connected with this issue, much as I could say about them. But I cannot allow myself to be saddled, both by Dr. Hurter and Mr. Davis, with a statement which I entirely repudiate, viz., that the quantity of nitre lost in the chambers, or "in a manner not yet clearly understood" (as Dr. Hurter puts it), is 75 per cent of the total consumption, *whatever that may amount to*. In truth I am not guilty of such an assertion, which, as exemplified by Mr. Davis, involves a downright absurdity. At some factories only 2½ parts, at others—not fitted with recovery apparatus—up to 13 or 14 parts of nitre are used for 100 sulphur; and I am made to say that in either case the loss in the chambers is three-fourths of the total loss! In my letter I had, for the sake of argument, adopted Dr. Hurter's calculation, starting from a loss of 4 parts of nitre on 100 sulphur; and I had proved that, upon his own showing, coupled with evidence referring to the only point in which the two cases differ, the "chemical loss" at works denitrating by steam should be 75 per cent of the above, i.e., 3 parts of nitre to 100 sulphur. Mr. Davis applies that 75 per cent to works where the nitre was not recovered, and where 3 parts were consumed for 100 vitriol, or, say, 9 parts for 100 sulphur, so that my alleged 75 per cent would come to 6.75 parts instead of *three parts*. Dr. Hurter puts the

chemical loss of nitre at works having no recovery apparatus, which notoriously consume 10 to 12 parts of nitre to 100 sulphur, at 20 per cent,—i.e., 2 to 2.4 parts, which is not so very far from my 3 parts. Dr. Affleck, by increasing the absorbing space, has brought down the loss of nitre from 1.45 to 1.05 upon 100 pyrites, or, say, from 3.2 to 2.5 upon 100 sulphur, and he expects ultimately to come down to 0.75 nitre on 100 pyrites,—i.e., 1.67 on 100 sulphur. Even then there might be some loss of nitre in the exit gas as NO. But if we confine ourselves to the consumption of 2.5 parts of nitre, realised by Dr. Affleck as well as by some continental manufacturers (the instance quoted by Mr. Davis, 16 cwts. nitre to 100 tons of vitriol, comes to even less than that), and if we subtract from it the 0.6 part allowed by Dr. Hurter (as 15 per cent of 4 parts) for "mechanical losses" in other ways, the maximum of possible "chemical loss" is reduced to 1.9 parts of nitre to 100 sulphur. But that is only a maximum figure; the real figure, if the exit gas was treated more thoroughly, according to Dr. Affleck might be 1.67, less 0.6 for other mechanical losses, or merely 1 part of nitre to 100 sulphur—not 3 parts, as I had temporarily admitted entirely for argument's sake. In short, it is quite impossible to make even an approximately definite statement of the "chemical loss," and just for that reason I refrained from doing so in my treatise.

I hope that enough mere arguments have been exchanged now. Let us rather try to approach the solution of the difficulty in an experimental way. This I, for my part, have commenced to do in the investigation which I mentioned as being about to appear, and I am continuing my labours in this field.—I am, &c.,

GEORGE LUNGE.

Technical Laboratory of the Federal
Polytechnic Schools, Zürich.

THE CHEMICAL REACTIONS OF THE HOLLWAY PROCESS.

To the Editor of the Chemical News.

SIR,—The reactions which take place in the Hollway process of rapid oxidation must appear to chemists who have had the privilege of studying the matter to be very interesting (some of those reactions being entirely new), and to be well worth studying.

It is well known, of course, that if iron pyrites is heated in a neutral atmosphere, the result is ferrous sulphide and free sulphur (or something approaching it); but it is not so well known that when ferrous sulphide is heated at a higher temperature, it splits up into a lower sulphide and free sulphur ($2\text{FeS} = \text{Fe}_2\text{S}_3 + \text{S}$). At all events, on blowing through the molten sulphides in a Bessemer converter, sulphur was seen burning abundantly at the mouth, and condensed in the tubes for collecting the gases.

Moreover, as I pointed out at the adjourned meeting of the Society of Arts, the regulus of at least two of the experiments contain sulphur in the proportion to form Cu_2S and Fe_2S_3 .

I.		II.	
Iron ..	57.10	Iron ..	56.05
Copper ..	15.85	Copper ..	16.59
Sulphur ..	21.96	Sulphur ..	23.47

I believe it to be the accepted explanation of the production of moss copper in blue and white metal (at least it is the one given by Percy as the most reasonable) that the subsulphide of iron might be formed, which in presence of subsulphide of copper would form ferrous sulphide and metallic copper ($\text{Fe}_2\text{S}_3 + \text{Cu}_2\text{S} = 2(\text{FeS}) + 2\text{Cu}$); and in connection with this Mr. Schweder finds that by melting subsulphide of copper and metallic iron together the result is ferrous sulphide and metallic copper,—

He also failed to produce subsulphide of iron, and declares that it does not exist.

Of course these results of Mr. Schweder's confirm, to a large extent, what was known or believed by metallur-

gists, but in the Hollway process we find both the subsulphides of iron and copper existing together. It contains no metallic copper, and I have failed to find metallic iron in a similar regulus produced by the same process. Moreover, I consider it extremely improbable, in taking into consideration Mr. Schweder's experiments, that there should be metallic iron and no metallic copper, or so long as subsulphide of copper is present.

It is evident, of course, that the high temperature of the Hollway experiments might be the means of producing the subsulphide of iron, but one would naturally expect that, in cooling, metallic copper and ferrous sulphide would be formed.—I am, &c.,

WM. GALBRAITH.

Sheffield, May 19, 1879.

EXPLOSIONS IN FLOUR-MILLS.

To the Editor of the Chemical News.

SIR,—I noticed with interest the communication of Mr. Watson Smith in the CHEMICAL NEWS (vol. xxxix., p. 222), on the subject of explosions in flour-mills, and as few chemists have had practical experience (as I have had during the last fourteen years) in flour-mills, my observations might not be without interest. I have no doubt from all I have seen that Mr. Smith's explanation of the cause of the explosions is the true one, but I was not aware that he was the first to give it, being under the impression that Dr. Stevenson Macadam had made a very complete investigation immediately after the Glasgow explosion, and arrived at the same conclusions as those now given by Mr. Smith. The remedies Mr. Smith suggests are very difficult to carry into practical operation, as millers require a number of small lights disposed over the mill, and at present the electric light does not conveniently give these. The best plan is to dispense with the stove-rooms altogether, and to filter the air through flannel cloth as it leaves the stone case. This can be done to great advantage by the use of Messrs. Seck's automatic apparatus, which has proved here a perfect success, as not a particle of flour leaves the stone case as dust, mixed with the exhaust air, and the exhaust is greater than without its use could be allowed. There is another source of danger besides that from the stone exhaust, and which it is supposed caused the immense explosion in four mills at St. Louis, U.S.; that is, the exhaust from the middle purifiers, in which the dust carried forward by the air is much drier than that from the stones, and therefore much more easily ignited. In this case also I recommend the filtration of the air immediately it leaves the purifiers. By these means the chance of an explosion is very much less, and should it occur will be much less powerful, as the volume of dust-laden air will be but a small fraction of what it would otherwise be without the filtration process.—I am, &c.,

ARTHUR McDUGALL, B.Sc.

City Corn Mills Manchester, May 26, 1879.

PS.—Mr. Smith suggests the use of an electric lamp in the stove-room. No light is required in that room, with such, if of sufficient volume, need only be entered once per week to be cleared out, and that can be done during the day.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 16, April 21, 1879.

Complementary Researches on the Products of the Distillation of the Alcohols.—I. Pierre and E. Puchot.—The title of this paper is misleading; the

authors treat of the distillation of various commercial forms of ethylic alcohol, and not of the alcohols as a generic group of compounds.

Artificial Preparation of Manganic Peroxide.—A. Gorgeu.—The author produces this compound by heating nitrate of manganese in a glass phial, placed in an oil or paraffin bath, to 155° to 162°. He supposes that in the natural formation of polianite and pyrolute iron suspended in the very fluid mass of nitrate of manganese has been first drawn off, the decomposition of the manganous nitrate taking place subsequently.

On the Tri-tungstates.—J. Lefort.—The author treats of the salts which result from the decomposition of the best known earthy and metallic acetates by sodic tri-tungstate. Equivalent proportions of the two salts are dissolved in a minimum of water. The tri-tungstates are generally instable, and if dried in the water-bath and treated with water they are more or less completely resolved into insoluble bitungstates and soluble quad-tungstates.

Letter to M. Dumas Concerning the Apparatus of Lavoisier.—P. Truchot.—Lavoisier's chemical laboratory and physical cabinet have been reverently preserved by his family, and are now in the possession of M. E. de Chazelles, at Canière, near Aigueperse, Puy de Dome, where the author has seen them. The smallest of the three balances is sensitive to $\frac{1}{10}$ grain. The weights belonging to these balances are wanting, but the kilogramme and its subdivisions as established by Fortin are present, recalling the fact that Lavoisier made all the determinations needful for fixing the weight of the kilogramme. There is a small model of an apparatus for the distillation of sea-water. There are a considerable number of precious stones, some of which have undergone the action of fire. Lavoisier is known to have made an experimental comparison of the heat produced by converging lenses with that of the blowpipe fed with oxygen.

Chemical Function of Anhydrous Acetic Acid.—M. Loir.—Anhydrous acetic acid yields alcohol when treated with a hydrogenising agent. When combined with sodic bisulphite it produces a crystalline compound. With ammonia it forms a crystalline compound insoluble in ether. Finally, acetic anhydride is greedy of oxygen.

On Nitroso-guanidin.—L. Jousselin.—The author prepares this compound by stirring up dry nitrate of guanidin in fuming nitric acid and passing a current of nitrous acid through the mixture. He examines its behaviour with acids, alkalies, and reducing agents.

Value of Certain Chemical Agents Employed in Printing Aniline-blacks.—G. Witz.—The vanadic compounds have been employed for several years in printing textiles. On adding them in extremely minute quantities to thickened mixtures of aniline salts and of chlorates the generation of aniline-black is produced with a rapidity proportional to the doses of vanadium employed. In a letter, published in the *Comptes Rendus* for the session November 25, 1878, M. S. Grawitz has held up chromic compounds as possessing a greater energy than those of vanadium. He founds this opinion upon an experiment in which $\frac{1}{4}$ milligram. bichromate of potassa to a litre of a mixed solution of aniline hypochlorate and of chlorates is said to have produced a colour intense enough to form a kind of ink upon paper. M. Witz has shown that a result such as described, and with such a proportion of chromate was inaccurate (*Comptes Rendus*, December 30, lxxvii.), and subsequently, M. Grawitz, in a further communication, by his silence on this point, seems not to contest the refutation of his original experiment. The modifications introduced by M. Grawitz at the same time, both in the proportions announced and in the nature of the chromates which he now selects in a neutral state (session of February 24, 1879), have given no better results in the check experiments undertaken. It cannot be otherwise, since chrome in its various conditions—and especially

as the chromates of potash, soda, or ammonia—is essentially inert as regards the mixtures of chlorates at the temperature at which the operation is conducted. Here M. Witz considers is the capital error of his opponent, whilst a trace of vanadium acts upon the chlorates in an indefinite manner. The chromates, when in contact with salts of aniline and in a suitable state of concentration, are reduced as soon as the reaction commences, and in proportion as they act they pass into that state of chromic sesquioxide, which remains insoluble and inactive in spite of the presence of the chromates. It is therefore necessary to use quantities of the chromates relatively considerable, because their action takes place only in equivalent quantities. Thickened mixtures containing chromates coagulate rapidly, and to obviate in part this inconvenience M. Grawitz adds ammonia, a device introduced by M. Witz to get rid of any excess of free acid retained among the crystals of aniline hydrochlorate, and which has been well-known and generally used for three years. With this addition, though the development of the colour is slightly retarded, the doctors are completely preserved from corrosion and the design remains clear. When, however, ammonia is used along with the chromates the black is developed suddenly but too much on the surface of the cloth; a certain part of the thickening remains coagulated upon the fibre, and the shade produced has not the intense clear black tone produced with copper or vanadium; it is brownish, imperfect, and much more readily attacked by chlorine. Thus the addition of the chromates to an ordinary colour is distinctly injurious. Even if ammonium vanadate costs 1 franc per gramme it is twelve times less expensive than copper sulphide paste, and certainly much less than the chromates, which act only in equivalent quantities.

Moniteur Scientifique, Quesneville.
May, 1879.

Industrial Society of Mulhouse: Sessions of the Chemical Committee (February 12).—M. Prud'homme described a new colouring matter recently introduced into commerce by A. Bayer under the name of anthracen violet. The author considers that it has no connection with anthracen, but is a substitution-product of gallein, with which it agrees in its reactions, its spectrum, and in the shades produced with different mordants. March 12. —M. Kallab in a note addressed to the Committee admits that his new process for bleaching animal fibres does not yield a white equal in beauty to that produced by the old method, but thinks that the new white, being more permanent, should be preferred where a greenish shade is not objected to. MM. Schmidt and Baldensperger communicated a description of their new processes for the manufacture of magenta by means of vanadium chloride and of certain nitro derivatives, such as nitro-naphthalin. Both yield magenta of excellent quality. Vanadium chloride is allowed to act at 200° upon a mixture of nitrobenzol and commercial aniline, or of pure aniline and nitro-toluol.

The remaining papers in this issue are already familiar to our readers, one dating back as far as 1865.

Biedermann's Central-blatt.
Heft 2, February, 1879.

Belgian Phosphorites.—Prof. Petermann, Crispo, and Mercier.—The enormous phosphatic deposits of Ciply consist of four beds with the following average proportions of phosphoric acid:—

Tuffeau	0.11 per cent
Pierres dures	5.98 "
Craie grise	11.25 "
Poudingue de la Malogne ..	19.75 "

The last mentioned occurs very irregularly and in thin layers, which in many places are already exhausted. The

available quantity of the Craie grise is calculated at 14½ millions cubic metres. Many attempts have been made to render this mineral soluble by steeping in water containing carbonic acid, in solutions of alkaline and ammoniacal nitrates, sulphates, &c., and in the drainage of dung-hills, but the results have been negative. In case of dung-hill liquor the phosphates already existing in solution have been precipitated. The Craie grise has also been applied to soils in the raw state, but without any appreciable effect upon the crops.

Action of Gypsum upon the Quality and Quantity of Clover Crops.—Prof. A. Pasqualini.—In the experiments described the yield of clover was increased, but its nutritive value underwent no improvement.

Excretion of Phosphoric Acid in the Herbivora.—Dr. J. Bertram.—In the carnivora the phosphoric acid introduced into the system is almost exclusively excreted in the urine, whilst in herbivorous animals, under normal circumstances, it appears in the solid excrements, and is not to be detected in the urine unless the lime present in the food is not sufficient for its neutralisation.

Influence of Food on the Quality and Quantity of the Fat of Milk.—Both the percentage and the absolute quantity of fat in milk may vary considerably, even when the diet is unchanged. An addition of protein to the food increases the proportion of fat, but not so much as an addition of oil or stearic acid. The fat of cream melts about 2° lower than the fat remaining in skimmed milk.

Researches on the Ripening of Grapes and other Fruits.—C. Portele.—The ripening of stone fruit after being gathered consists in a decided decrease in acids and in cellulose, whilst the total proportion of sugars is lessened slightly, and in the dextrose is converted into levulose, which is sweeter. There is also under the same circumstances an increase of levulose in grapes, though to a less extent.

Purification of Saccharine Juices with Hydrate of Alumina.—Dr. O. Kohlrausch.—This process, introduced by Prof. Löwig, dispenses with animal charcoal and with the production of treacle. The author finds, however, that a certain quantity of alumina dissolves in the juices, so that the mineral acids present and also the colour are not entirely removed. Hence it is very doubtful whether the filtration over animal charcoal could be omitted. The production of treacle is also not obviated in Löwig's process. The elutriation of the hydrate of alumina requires

such quantities of liquid that the boilers and presses would require to be enlarged, and the consumption of fuel would be increased.

Foreign Colouring Matters in Red Wines.—Prof. J. Nessler.—The author considers that we are not yet able to distinguish the red colouring matters of mallows and bilberries from that of grapes. It is very probable that they do not essentially differ.

On Casein.—Prof. O. Hemmarsten.—The author prepares casein by precipitation with acetic acid, avoiding excess, re-solution of the washed precipitate in a minimum of alkali, so that the liquid retains a faint acid reaction, filtration to remove fat, re-precipitation with acetic acid, and after several repetitions of the above-described process washing with alcohol and ether. Pure casein possesses the characters of an acid; if dissolved in a minimum of caustic alkali it has an acid reaction; it dissolves the carbonates of lime and baryta with liberation of carbonic acid, and even phosphate of lime.

Heft 3, March, 1879.

Temperature of the Soil in a Compact and a Loose Condition.—Prof. E. Wollny.—In summer and in warm weather compact soils are on the average warmer than loose ones, but in winter, and on a fall of temperature in summer, they are colder. In warm weather compact soils are warmer by day and colder by night than loose ones, and are subject to greater fluctuations of temperature.

Composition of the Milk of Cows of Different Breeds.—E. Marchand.—The author finds free lactic acid, a constituent hitherto invariably overlooked, present to the average amount of 2 grms. per litre. The relative proportions of albumen and casein fluctuate much, but their joint weight is little affected. If the cow has eaten cruciferous plants the milk is rendered poor in casein and rich in albumen, thus effecting the production of cheese.

Composition of Clover-hay Rapidly Dried or Exposed to Rain.—Dr. C. Brimmer.—The quantity of protein is reduced 0·7 per cent, but the non-nitrogenous extractive matters are diminished by 7·1 per cent.

Artificial Horse-dung.—Prof. Mayer.—A manure is said to be exported from England to Holland which has the outward appearance of stable manure, but on examination proved to be a mixture of straw and decayed leaves.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATER.

APRIL, 1879.

THE following are the returns of the Society of Medical Officers of Health:—

Appearance in a foot Tube.	Ammonia.		Nitrogen as Ni- trates, &c.	Oxygen used to Oxidise Organic Matter.	Total Solids.	Lime.	Magnesia	Chlorine	Sulphuric An- hydride.	Hardness on Clark's Scale.

The quantities of the several constituents are stated in grains per imperial gallon.

NOTE.—The amount of oxygen required to oxidise the organic matter, nitrites, &c., is determined by a standard solution of permanganate of potash acting for three hours.

C. MEYNOTT TIDY, M.B.

NOTES AND QUERIES.

Manufacture of Sulphuric Acid.—Has it ever been suggested that the pot containing nitre or nitrate of soda and sulphuric acid be replaced by one containing sulphur and nitric acid, so that the manufacture of a by-product, and the heat, time, and labour consequent thereon be avoided. Of course this plan would not be so suitable for stone acid manufacturers. The principal objection would seem to be the greater cost of the nitric acid, but when the densities of the former and sulphuric acid are taken into account, the cost is considerably lessened.—**SULPHURIC ACID, Swansea.**

Mineralising Flannel.—Can you or any of your readers inform me of a process by which flannel may be mineralised or preserved from the action of a continuous flow of water at a high pressure in which it is immersed, as I find that after a few months use the flannel loses its nature, the threads being partially decomposed? Would water have the same effect upon silk?—**ANDREW BELL.**

Blue Manifold Paper.—Will you kindly favour by answering, through the columns of your valuable paper, a recipe for making blue manifold paper.—**B. M. P.**

MEETINGS FOR THE WEEK.

- MONDAY, 2nd.**—Royal Institution, 3. "The Intellectual Movement of Germany from the Middle of the Last to the Middle of the Present Century," Prof. Hillebrand.
General Monthly Meeting, 5.

UNIVERSITY OF LONDON.
NOTICE IS HEREBY GIVEN, That the next Half-yearly Examination for **MATRICULATION** in this University will commence on **MONDAY, the 30th of June, 1879.** In addition to the Metropolitan Examination, Provincial Examinations will be held at Owens College, Manchester; Queen's College, Liverpool; Queen's College, Birmingham; St. Cuthbert's College, Ushaw; Stonyhurst College; St. Patrick's College, Carlisle; St. Stanislaus College, Tullamore; University College, Bristol; and (for Ladies only) at the Ladies' College, Cheltenham.
Every Candidate is required to transmit his Certificate of Age to the Registrar (University of London, Burlington Gardens, London, W.) at least Fourteen Days before the commencement of the Examination.

WILLIAM B. CARPENTER, M.D.,
Registrar.

DR. LUNGE'S NITROMETER.

This Apparatus, for the Determination of Nitrous and Nitric Acids, as described in **CHEMICAL NEWS** of July 12th, can now be supplied. Absorption Apparatus for Oxygen Estimation now ready. Particulars on application.

MAWSON and SWAN Newcastle-on-Tyne.

With 94 Engravings, crown 8vo., 12s. 6d.

SANITARY EXAMINATIONS of WATER, AIR, and FOOD. A Vade-Mecum for the Medical Officer of Health. By CORNELIUS B. FOX, M.D., Lond., Medical Officer of Health of East, Central, and South Essex.

"His clear, practical, and common-sense manual."—*Chem. Rev.*
"Eminently practical, yet scientific. . . One of the best contributions to the literature of hygiene which has been made within the last few years."—*Dub. Med. Jour.*

"In the execution of his task the author has wisely adopted a style as free from technicalities as possible, so that one who possesses only the average chemical knowledge of a qualified medical practitioner may, by the aid of the handbook, instruct himself in the methods of sanitary examination."—*Med. Times and Gaz.*

By the same Author, Second Edition, with 9 Engravings, crown 8vo., 1s. 6d.

THE DISPOSAL of the SLOP-WATER of VILLAGES.

London: J. and A. CHURCHILL.

Now ready, fcap. 8vo., 2s. 6d.

SKELETON NOTES on ANALYTICAL CHEMISTRY for STUDENTS in MEDICINE.

By **ALBERT J. BERNAYS**,
Professor of Chemistry at St. Thomas's Hospital Medical College;
Examiner in Chemistry at the Royal College of Physicians.

By the same Author, Sixth Edition, fcap. 8vo., 3s. 6d.

NOTES for STUDENTS in CHEMISTRY:

A Syllabus.

London: J. and A. CHURCHILL.

NEW EDITION of MUTER'S CHEMISTRY.

Just published in two Vols. as follows:—

Vol. I.—AN INTRODUCTION TO CHEMISTRY (Theoretical and Descriptive). Second Edition. 400 pp., royal 8vo., price 10s. 6d.

Vol. II.—AN INTRODUCTION TO ANALYTICAL CHEMISTRY. Second Edition. 216 pp., royal 8vo., with copious tables and concise instructions for the qualitative and quantitative analysis of metallic salts, alkaloids, water, &c., price 7s. 6d.

This well-known work, although specially designed for pharmaceutical and medical students, will be found very useful to all commencing the study of general chemistry, the novel principle on which they are arranged ensuring a rapid and comprehensive grasp of the subject by the learner.

London: Published by **W. BAXTER** at the Office of the South London School of Pharmacy, Kennington Cross, and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox, and at all booksellers.

INSTITUTE OF CHEMISTRY.

The President has offered Two Prizes of £50

each for the two best original investigations involving Gas Analysis. These Prizes will be open to Associates, and to all persons (except Fellows of the Institute) who shall before the 31st December next have qualified for the Associateship in all respects short of passing the prescribed practical examination, and successful competition for these prizes will be accepted in lieu of such practical examination.—Further information may be obtained on application to the Secretary, Mr. C. E. GROVES, Somerset House Terrace, W.C.

Advertiser (22), trained in the Science Schools, South Kensington, seeks an Engagement in Chemical or other Scientific Laboratory.—Address, G.C., 59, Robert Street, Chelsea, S.W.

A Young Man (19), who has had two years experience as Assistant in the Laboratory of a Chemical Works, seeks a similar position. Highest references.—Address, J. R. W., 91, Belmont Row, Birmingham.

A Chemist, trained at Royal School of Mines, with Eight Years' practical experience, desires an Engagement. Excellent references.—Apply F. I. C., **CHEMICAL NEWS** Office Boy Court, Ludgate Hill, London, E.C.

Advertiser, with Six Years' Experience in Analytical Chemistry, desires an Engagement as Assistant or as Chemist in Works. No objection to go abroad.—Apply, H.H., **CHEMICAL NEWS** Office, Boy Court, Ludgate Hill, London, E.C.

Wanted an Intelligent Workman who thoroughly understands the manufacture of Acetic Acid and other Wood-products.—Apply to "Wood," **CHEMICAL NEWS** Office, Boy Court, Ludgate Hill, London, E.C.

Wholesale and Export Dealers and Manufacturers of
CHEMICAL & SCIENTIFIC APPARATUS
PURE CHEMICALS, &c.,

For Analysis and the general Laboratory Use of Manufacturers and Professors of Universities, Schools, Mines, &c.

Now ready,

TOWNSON & MERCER'S COMPLETE CATALOGUE of Chemical and Scientific Instruments, Pure Chemicals &c. Demy 8vo. Illustrated with upwards of 800 Woodcuts. Price 2s. 6d. post free.

PATENTS.—Mr. Vaughan, F.C.S., British, Foreign, and Colonial PATENT AGENT. Special attention given to Inventions relating to Chemistry, Mining, and Metallurgy "Guide to Inventors" Free by Post.—Offices, 67, Chancery Lane London, W.C., and 8, Houndgate Darlington.

MINERALOGY AND GEOLOGY.

NEW LIST of Collections of Minerals, Fossils, and Rocks, with prices. New List of Minerals for Chemical Purposes, Manufactures, and Research. New List of Varieties of Rocks. New List of Prices and Sizes of Cabinets for Natural History and other purposes. New Catalogue of Secondhand and New Books on Geology and Kindred Sciences. New Supplementary List of Books. New List of Sections of Rocks and Minerals for the Microscope. New List of Prices and Patterns for Geological Hammers. New List of Blowpipe Cabinets, Apparatus, and Materials. Also Implements and Appliances for practical work in Geology and Mineralogy.

Post free on application to JAMES R. GREGORY, Geologist and Mineralogist's Repository, 88, Charlotte Street, Fitzroy Square, London.

Water-Glass, or Soluble Silicates of Soda and Potash, in large or small quantities, and either solid or in solution, at ROBERT RUMNEY'S, Ardwick Chemical Works, Manchester.

ORGANIC MATERIA MEDICA.
By DR. MUTER.

Analytical Chemists will find this a concise and yet complete book of reference for the isolation and examination of the active principles of drugs. Special appendix on the microscopic characters of the starches in food and drugs. Copious index and qualitative courses or resins, &c.

Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, S.E., and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox.

IMPORTANT TO SULPHURIC ACID MANUFACTURERS.
NORRINGTON'S PATENT.

In the ordinary method of Manufacture, at the time of charging the Kilns, a considerable escape of gases takes place. This is attended with proportionate loss of Sulphur, and with much inconvenience to the workmen, as well as annoyance to the vicinity of the Works. This may be entirely avoided by the adoption of C. Norrington's patented invention, which can be applied at moderate cost to existing Plant, as well as in the erection of new Works. It may be seen in full operation on extensive Plant at Messrs. C. Norrington and Co.'s Chemical and Manure Works, Cattedown, Plymouth, where the fullest information may be obtained, with terms for license.

CHEMICALS.—Complete Fittings for an Amateur Laboratory. Open Cabinet, eight feet and a half high by nine feet long; Quantity of Chemicals in stoppered bottles; Apparatus, including two large Bunsen burners and stoves, with blue pipes. Price as they stand in Plumstead £15; can be seen by appointment.—Address, P. L. 40, Deacon's Advertisement Offices, Leadenhall Street, E.C.

TO CHEMISTS AND DRUGGISTS.

The Shop, 140, Leadenhall Street (in which a Chemist's Business has been successfully carried on for nearly 180 years), to be Let on 21 years Lease (in consequence of existing Tenants retiring from business), with possession on July 10, 1879. For further particulars apply to Messrs. Jones, Lang, and Co., 5, King Street, Cheapside, E.C.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and Co., Clayton, near Manchester.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1019.

9 JUN 79

NOTE ON THE SPECTRUM OF SODIUM.

BY J. N. LOCKYER, F.R.S.

I HAVE lately been engaged in studying the spectrum of sodium under new experimental conditions. In anticipation of a detailed communication I take leave to state that the vapour given off from the metal after slow distillation in a vacuum for some time shows the red and green lines without any trace whatever of the yellow one. Hydrogen is given off in large quantities, and at times the C line and the red "structure" are seen alone. After this treatment the metal, even when red hot, volatilises with great difficulty.

PRELIMINARY NOTE ON THE ABSORPTION OF SELENIUM BY PLANTS.*

By CHARLES A. CAMERON, M.D.,
Professor of Chemistry and Hygiene, R.C.S.I.

The subject of the possibility of replacing some of the elements found in plants by other elements of the same atomicity has not engaged the attention of British chemists; but on the Continent a few attempts in this direction have been made, generally with but little success. For example, Berner and Lucanus vainly attempted to replace ferric oxide (Fe_2O_3) in plants by the manganese analogue of that compound (Mn_2O_3). Experiments made with the view of substituting sodium for potassium in plants have invariably given negative results. The possibility of completely replacing an element in plants by another was, however, proved by me in a paper read before this Society in 1863. I found that rubidium was capable of taking the place of potassium. It may be that certain bodies, though not capable of completely replacing other substances in vegetables, may be partially substituted therefor. The varying proportions of sodium and potassium found in the ashes of plants would seem to indicate such a partial replacement. As a rule, whenever potassium is sparsely present in the ashes of a plant, sodium abounds therein, and *vice versa*.

The analogy between sulphur and selenium suggests the possibility of the latter wholly or partly replacing the former as a constituent of vegetables. Sulphur exists in plants on two conditions, namely, as a constituent of sulphuric acid, and as an ingredient of albuminous and certain oily bodies. Sulphur is only taken up into the mechanism of plants in the form of sulphates, such as, for example, calcium and sodium sulphates. By the partial deoxidation of these sulphates, sulphur is procured by the plant and employed in the elaboration of its albumen, casein, and other albuminoids. The results of the interesting experiments of Arendt render it probable that sulphur is both oxidised and deoxidised in the plant at different periods of its development. Thus, after blossoming the oat was found to contain more sulphur trioxide than before the ears of the plant had formed; and whilst the sulphur trioxide disappeared altogether from the lower part of the stem, it increased largely in the leaves and in the plant at large.

Now, there are two problems to be solved in relation to the substitution of selenium for sulphur in plants. First, can selenium in the form of selenic acid replace sulphuric

acid? Second, can selenium replace sulphur as a constituent of albuminous bodies? If it were possible through the agency of the organs of plants to effect the replacement of an element not merely in an organic, but in an organised body, the achievement would be one of the greatest importance. Absolutely nothing has been done in the way of effecting the synthesis of new bodies by means of the wonderful combining powers which are exerted in the vegetable mechanism.

The difficulty with which compounds of selenium analogous to the organic bodies containing sulphur are prepared, and the instability of so many of them, are facts which deter one from feeling sanguine as to the possibility of effecting the synthesis of organised selenium bodies by means of plants; still the attempt is worth making. Much more hopeful is the chance of replacing sulphuric acid by selenic acid. I am of this opinion from the results of an experiment which I made several years ago upon a very small scale, and which I never published up to the present, every year intending to repeat it upon a larger scale. The experiment was as follows:—A sod was taken from a field in which a crop of the so-called artificial grasses (which are chiefly leguminous plants, and not grasses at all) was just peeping over ground. The sod was 2 feet in depth, 3 feet in length, and 1 foot wide. It was placed in a box, and one-half of the plants were watered twice a week with a weak solution of potassium selenate (K_2SeO_4). During four weeks the total quantity of potassium selenate applied to the plants amounted to 20 grms., which comprised my whole stock of the article.

Now, this experiment was merely a tentative one. First, to ascertain whether or not selenic acid would act injuriously upon plants. Secondly, to discover whether or not the selenic acid could partly replace the sulphuric acid, or rather could be taken up into and permanently retained by the plant. With respect to the action of the selenate, I could not perceive any difference between the plants to which the salt had been applied and those to which it had not. I came to the conclusion, therefore, that selenic acid applied at least in small quantities did not injure plants.

The next step was to ascertain whether or not the selenic acid had been partially absorbed. The plants were accordingly partially dried, and boiled in strong nitric acid until thoroughly destroyed. The solution was evaporated to dryness, and the residue was treated with dilute hydrochloric acid, which dissolved it nearly completely. The solution was concentrated and mixed with a saturated solution of sulphurous acid, whereupon the liquid assumed at once a deep blood-red colour, from the separation of selenium.

Before the plants were partially dried they were carefully washed, in order to separate any traces of selenate which might have adhered to their surface. The application of the selenate solution was discontinued for a fortnight before the plants were taken up.

I think this experiment proves that selenic acid is not injurious to plants when used in small quantity, and that the acid is taken up and retained by plants, or at least of certain varieties of plants. The experiment, however, did not prove whether or not there was a partial replacement of sulphur trioxide by selenium trioxide or of sulphur by selenium. Having lately become possessed of large quantities of selenium compounds, I proposed to grow plants in soil or water free from sulphur in any form, but supplied with potassium and ammonia selenates. Should the results of this proposed experiment prove interesting I shall do myself the honour of submitting them to the Society.

Proportion of Carbonic Acid in the Atmosphere.—J. Reiset.—The air contains in 10,000 parts 2.942 parts of carbonic acid by volume. The most extreme variations have not exceeded 3 parts in 10,000.—*Comptes Rendus*.

* Paper read before the Royal Dublin Society, May 19, 1879.

ON AURIN.* PART II.

By R. S. DALE, B.A., and C. SCHORLEMMER, F.R.S.

SOME time ago we read a paper before this Society, in which we stated that on heating aurin, $C_{19}H_{14}O_3$, with an excess of aqueous ammonia, it is converted into parosanilin, $C_{19}H_{17}N_3$.† There ought to exist two compounds standing intermediate between aurin and rosanilin, viz., $C_{19}H_{15}NO_2$ and $C_{19}H_{16}N_2O$, as the action of ammonia probably proceeds in three stages:—

We have made a very large number of experiments for the purpose to get hold of one of these intermediate products, and have at last succeeded in obtaining one, probably the first, in beautiful crystals; it dyes on silk and wool a rich red, and as the commercial red aurin, which is obtained by the action of ammonia on common or yellow aurin, has also been called *peonin*, we will retain this name for our compound. It is formed by heating aurin with dilute ammonia to $100^\circ C$. for some weeks. A body dyeing exactly the same shade, and therefore undoubtedly the same compound, is obtained by passing for a few hours ammonia gas into a solution of aurin in boiling amyl alcohol.

As we encountered many difficulties in the preparation of peonin, we thought more definite results might be obtained by using a compound ammonia, and therefore tried the action of methylamin on aurin. Methylamin is now a commercial article, being obtained from beetroot-molasses by M. Vincent's method, which Dr. Roscoe described to this Society some weeks ago; he was kind enough to present it with the methylamin required for our experiments.

On heating the two bodies together for a few hours, the deep red colour of the liquid became much paler, and a brown deposit was formed in the tubes, which on examination was found to be *trimethyl-para-rostanilin*, which is formed according to the equation—

We have dyed with it, as well as with the other bodies mentioned in this paper, silk, wool, and mordanted cotton, and beg to submit these samples to your inspection.

We have already proved that by acting on aurin with aniline the final product consists of triphenyl-parosanilin, and thus shown that the whole host of bodies known as the aniline colours can be obtained from phenol.

ON THE COMPOSITION OF THE ASHES OF WHEAT- BRAN, BURNED UNDER A STEAM-BOILER.

By S. F. PECKHAM.

SOME time ago, at a meeting of the Minnesota Academy of Natural Sciences, a substance was handed me by someone present with the remark that it was the fused ashes of wheat-bran, burned under a steam-boiler. The material was nearly pure white in colour and vesicular in structure, resembling more nearly some specimens of Cooper River phosphate than anything else that I remember. Wishing to learn its composition I submitted it for analysis to Miss Cora J. Brown, then a student in the University Laboratory. Miss Brown had already proved herself a very careful and skilful manipulator, and she conducted the analysis with exquisite neatness and patience, and with the most gratifying results.

The material had the appearance of having been completely fused, and was very free from even minute specks of either charcoal or sand. It had a specific gravity of 2.34, and a hardness of 3.5 to 4.

The analysis gave the following results:—

	Per cent.
Chlorine	0.612
Sulphuric oxide (SO_3)	0.151
Silicic " (SiO_2)	0.627
Phosphoric " (P_2O_5)	48.328
Potassium " (K_2O)	6.659
Sodium " (Na_2O)	6.664
Calcium " (CaO)	10.615
Magnesium " (MgO)	18.980
Ferric " (Fe_2O_3)	2.015
Water	0.438
Sand	3.170
	98.259

Which may be interpreted as indicating the following composition for the ash:—

	Per cent.
Potassium chloride (KCl)	1.2887
" silicate (K_4SiO_4)	2.5936
" phosphate (K_3PO_4)	5.8337
Sodium phosphate (Na_3PO_4)	11.7370
Hydrogen phosphate (H_3PO_4)	9.3721
Calcium sulphate ($CaSO_4$)	1.9567
" phosphate ($Ca_3(PO_4)_2$)	18.2342
Magnesium phosphate ($Mg_3(PO_4)_2$)	41.4600
Ferric phosphate ($Fe_2P_2O_8$)	3.8058
Water, hygroscopic (H_2O)	0.4379
Sand, insoluble residue.. .. .	3.1700
	99.8897

The remarkably large percentage of phosphoric oxide present at once attracted my attention, and at my suggestion the determination was repeated. The results of the four determinations made with uranium acetate were very closely concordant, and I think of unimpeachable accuracy.

No carbonic oxide (CO_2) was present. The very small proportion of chlorine is doubtless due to the high temperature to which the ash had been subjected—a temperature sufficiently high to completely fuse it. The substance may therefore properly be considered an ash residue consisting of its less volatile portions. The presence of free phosphoric acid in such a compound may be questioned; perhaps also the presence of normal magnesium phosphate. It must be remembered, however, that it is scarcely a supposable case that the phosphates in the bran are acid phosphates, producing pyrophosphates when burned; and while it would appear more probable that the albuminoid phosphorus contained in the bran would burn into phosphoric oxide and escape in the smoke, it is not a necessary supposition, especially when the results of analysis show that there is more phosphoric oxide present than is sufficient to form normal phosphates with the available bases. I have therefore assigned the composition given above as the most satisfactory interpretation of the results.

Laboratory of the University of Minnesota,
May 7, 1879.

Heat attending the Formation of Cyanogen.—M. Berthelot.—The mean heat evolved on the combustion of cyanogen, calculated for its equivalent $C_2N=26$, is 132.3 calories. In its formation heat is absorbed to the extent of 38.3 cal. Hence, like acetylen and nitric oxide, substances which play the part of true compound radicals, it is a body formed with disappearance of heat.—*Comptes Rendus*.

NOTE ON THE DETECTION OF SOME
RARE METALS IN PYRITES FLUE DUST.*

By DAVID PLAYFAIR,
Assistant in St. Rollox Laboratory, Glasgow.

THE flue dust which was examined was taken from a short flue leading from pyrites kilns in which Spanish cuprous pyrites were burned. As the flue in question was an iron tube not more than 2 or 3 yards long, anything that condensed in it must have done so at a very high temperature; and that probably accounts for the very small quantity of selenium found, as that metalloid is found in appreciable quantities in the sulphuric acid manufactured from these pyrites.

The greater part of the flue dust consisted of compounds of arsenic, antimony, lead, copper, and iron; but it is only the thallium, tellurium, and selenium that this note is concerned with.

Thallium.—The flue dust was treated with sulphuric acid for the extraction of the thallium, which was precipitated as chloride. The chloride was re-dissolved and re-precipitated twice, and then reduced to the metallic state with cyanide of potassium. One sample of flue dust, treated thus, gave about 0.05 per cent of thallium, while in another case the amount obtained did not exceed 0.002 per cent.

Tellurium.—The insoluble matter left after the above treatment with sulphuric acid was boiled in a solution of caustic soda. The solution was filtered off, acidified with hydrochloric acid, boiled, cooled, saturated with sulphurous acid, and boiled again, when the selenium and tellurium were precipitated. This precipitate was collected, dried, and then fused with cyanide of potassium in an atmosphere of coal-gas. The fused mass was allowed to cool, and then dissolved in warm water saturated with coal-gas, and through which a stream of coal-gas was kept continually passing, on a filter. The telluride of potassium thus dissolved passed through the filter exhibiting its characteristic claret colour, which it, however, immediately lost, becoming colourless, and precipitating tellurium unless a stream of coal-gas was kept passing through the filtrate also.

The amount of tellurium found was about 0.002 per cent of the matter undissolved by sulphuric acid in the treatment for thallium. The amount of selenium did not exceed 0.001 per cent.

CHEMICAL JOTTINGS.†

By H. R. PROCTER.

I. *Weselsky's Reaction for Phloroglucin.*

THIS reaction is described in the *Chemical Society's Journal*, 1876, i., 964, and consists in the production of a cinnabar-red precipitate when a trace of phloroglucin is added to a solution of nitrate of aniline or toluoydin containing a little nitrite, and the mixture allowed to stand some hours.

It is known through the researches of Hlasiwetz (*Ann. der Chemie*, cxliii., 290) and others, that many tannins when heated with dilute sulphuric acid are resolved into glucose and peculiar red bodies which we may call phlobaphenes. These again, when fused with potash, are decomposed into protocatechuic acid and another body, which in some cases is a fatty acid, and in others as the species of sugar known as phloroglucin.

To be able to recognise these phloroglucide tannins without the tedious process of separation noted above would be an important aid to the classification and qualitative

identification of these complex bodies; and it occurred to me that possibly they might give Weselsky's reaction in their unaltered condition. To test the matter, I mixed in test-tubes 5 c.c. water, 1 c.c. of a saturated solution of nitrate of aniline (probably containing toluoydin), and 1 c.c. of very dilute solution of potassic nitrite, and added to each tube 1 c.c. of solutions containing as nearly as possible 5 grms. per litre of the following bodies:—(See Table, next page.)

In five minutes most had become yellow, gambier, and oak, and churco barks deeply so, and in an hour oak and churco barks had deposited a deep red precipitate. In twelve hours all had precipitated more or less, but the glucose and sugar yielded only traces. The gambier, which contains catechin, a well known phloroglucide, gave a fine deep red precipitate, and oak and churco barks, which very probably contain phloroglucin, gave precipitates of which the lower part was equally bright.

It seems evident, therefore, that phloroglucides in combination may yield this reaction, but that many other bodies also give reddish-brown precipitates which may easily lead to mistaken conclusions. When more dilute solutions are used the same facts are observed, but the red precipitate is more distinct from the rest. Some precipitate was even obtained on long standing from aniline nitrate and potassic nitrite alone. The precipitates seem remarkably stable, being unaltered by solution of iodide, dilute acids, ammonia, sulphurous acid, or sulphide of sodium.

The yellow supernatant liquid, if acidified and exposed to the air, becomes bright crimson, and sometimes deposits minute crimson double-refracting acicular crystals. It is turned yellow by ammonia and its colour restored by acids.

Watts states that pyrocatechin gives Weselsky's reaction.

The churco bark to which I have alluded is the product of the *Oxalis gigantea* of Chili, and contains a red tannin equal in amount, by Löwenthal's test, to from 25 to 26 per cent. quercitannic acid. The sample in my possession was kindly supplied by Messrs. Machado, of Glasgow.

I have made some preliminary experiments as to the application of Wiesner's test for woody fibre—the purple colouration produced on moistening it with solution of phloroglucin and then with the hydrochloric acid (*Chemical Society's Journal*, 1878, p. 809)—to the converse detection of phloroglucides. Deal shavings moistened with solution of gambier gives it strongly. I hope to pursue the subject further.

II. *Explosive Product of Solution of Phosphorus in Bisulphide of Carbon.*

In packing my chemicals for removal to a new laboratory, I came upon two bottles of this solution, probably five or six years old, which had formed an orange-yellow deposit on the sides. Having recently read of a case, to which I am sorry that I cannot at the moment refer, in which a bottle with a similar deposit had exploded violently on being broken, I determined to try the experiment at once, lest it might try itself under more dangerous conditions. The bottles were thrown against a wall, and one exploded with a large puff of flame and white smoke: the other gave a slight flash, and smoke which smelt rather of phosphoretted hydrogen than of phosphoric acid. It is evident that some new and spontaneously inflammable compound had been formed, since the fresh solution only inflames after some minutes, when the carbon disulphide has had time to evaporate, and fails to do so at all when the temperature is very low. In the present case the thermometer was below freezing-point, and combustion was instantaneous. Phosphoretted hydrogen is out of the question, unless moisture had found its way into the bottle.

Of course I can claim no originality in this observation, but think it well to put it on record as a caution, sir—

* Read before the Chemical Section of the Glasgow Philosophical Society.

† Read before the Newcastle-upon-Tyne Chemical Society, March 27, 1879.

No.		In Five Minutes.	In One Hour.	After standing over night.
1.	Gallic acid	Yellow colouration	Orange, no precipitate	Dark red-brown precipitate
2.	Gallotannic acid	Ditto	Ditto	Ditto
3.	Gambier	Deep yellow	Orange, turbid	Venetian red precipitate (compact)
4.	Oak bark tannin (50 grms. bark per litre)	Ditto	Orange, red precipitate	Ditto, upper part darker
5.	Pyrogallol	Pale yellow	Orange, turbid	Reddish brown flocculent ppt.
6.	Churco tannin (20 grms. bark per litre)	Deep yellow	Dark orange, red precipitate	Red precipitate, flocculent, dark above
7.	Cane-sugar	Colourless	Clear yellow liquid	Trace brown precipitate
8.	Impure glucose	Ditto	Ditto	Ditto

the reaction might easily give rise to a dangerous accident.

III. Determination of the Free Acid in Tan Liquors.

Tan liquors usually contain, in addition to tannins, gallic acid, catechu, and other bodies of very feeble acid properties, a certain portion of acetic and other fatty acids, and frequently free sulphuric and hydrochloric acids, which have been purposely added. For technical purposes it is often desirable to determine these stronger acids, which are capable of dissolving lime and swelling the tissue of hide in presence of tannin, &c., which have the opposite effect. This cannot be done by an alkaline solution and litmus, since the tannins are immediately oxidised in alkaline solution, giving rise to dark coloured products, which obscure the end-reaction.

A simple and sufficiently accurate method for technical purposes is to use lime-water as the standard solution, adding it to the clear filtered liquor in a beaker until permanent turbidity is produced. This point is easily recognised by holding the beaker over a printed page. The end reaction, of course, depends on the fact that calcic tannates are soluble, or more probably cannot be formed in the presence of a free and stronger acid. I have not attempted to determine exactly *what* acids are estimated by this process, the mixture is complex, and the amount of lime which they are capable of dissolving is the essential point in practice.

REPORT ON THE EXPERIMENTS WITH THE ELECTRIC LIGHT ON THE VICTORIA EMBANKMENT.

THE joint official report of Sir J. W. Bazalgette, the engineer, and Mr. T. W. Keates, the consulting chemist of the Metropolitan Board of Works, has recently been made public, and is a model of what such a report should be.

For the first time in the history of the electric light, as applied to street illumination, we have a series of data laid before us about whose accuracy there can be no doubt. Hitherto such reports have emanated from either gas-managers or electricians, whose interests—wrongly we think—have been held to be opposed to each other; hence the singular discrepancies in the data which have been issued up to the present time. It must be perfectly understood that we in no way intend to make the slightest imputation against the honour of the authors of these reports; but when one side tells us that the electric light is cheaper than gas, and the other that gas is cheaper than the electric light, we can only account for the discordance of opinion by supposing that the reporters' judgment must have been unconsciously influenced by their anterior convictions. In the present instance we have the conclusions of two eminent public officials, who have no other interests to serve than those of the community at large, and who are wholly independent of the advocates or opponents of either system of lighting.

We regret that we cannot follow the reporters through all the elaborate series of calculations which they have laid before us; we can only gather a few of the results of

their carefully conducted experiments. One great point which has been decided on the Victoria Embankment is that the steadiness of the light is in a great measure dependent on the regularity with which the motive power is supplied to the electric machine. In the present case this uniformity of power was secured by the use of a specially constructed 20 horse-power engine, provided with an automatic governor of extraordinary sensitiveness, the whole being supplied gratuitously for three months by Messrs. Ransomes, Sims, and Head, of Ipswich.

The experiments upon which Messrs. Bazalgette and Keates's figures are founded began on January 24th, and were continued until February 5th, Sundays excepted, — or, in other words, for twelve nights,—the engine being driven for 5½ hours each night, the whole 26 lamps being lighted. The mean daily cost of working the engine, including wages, was found to be £1 9s. 8½d., or 3¼d. per lamp per hour. The cost of the whole plant was £1280, but a smaller engine would be quite sufficient for the purpose; the capital required, therefore, might be reduced to £990.

"The accurate estimation of the amount of light given off by the electric arc and ignited carbons is," say the Reporters, "a matter of great difficulty, so much so that the best results which have been obtained can only be looked upon as fairly approximating to the truth." This difficulty arises from two causes: first, from the difference in colour between the electric light and any standard of light at our command; and secondly, the fluctuating character of the electric light. The photometrical experiments made on the Embankment were—1st, on the naked light; 2ndly, on a light with an opaline globe; and 3rdly, on a light with a granulated globe. The measurements were made with an ordinary bar photometer, fitted with a movable screen with a star disk.

The standard unit of light which was used was a sperm oil lamp, specially constructed for the purpose by Mr. Sugg, and fitted to the photometer by a peculiar balance, by which the necessity for removing the lamp during the course of any number of experiments is obviated. The unit of light given by this lamp was equal to 16 Parliamentary standard sperm candles. Twenty readings were made on each experiment, both with open and shaded lights,—that is to say, 160 on the naked light, 24 with the opaline globe, and 16 with the granulated globe. The following are the mean results obtained in these experiments:—

Naked light	378.1 sperm candles.
Opaline globe	154.9 " "
Granulated globe ..	265.0 " "

The loss of light produced by the opaline globes is 59 per cent; by the granulated globes, 29.9 per cent.

Taking the above data as approximately correct, the gross output of light from the twenty Jablochhoff candles amounts to 7562 candles, nearly 60 per cent of which is absorbed at once by the opal globes. There are also two other sources of loss: first, from the greater thickness of the opal glass in the lower third of the globes; and secondly, from the fact that the most favourable direction for the projection of the light from the Jablochhoff candle is upwards, there being an actual diminution of light horizontally, and still more so downwards.

On the 14th and 15th of March a very important expe-

riment was made, with a view of ascertaining whether the circuits could be increased in length to a considerable degree without diminishing the apparent value of the lights on such circuits. The Westminster and Waterloo circuits—that is to say, the two at each end of the line—were thrown into one, the total length of wire being 7063 feet, three of the lights being at the Westminster end and the other two at the Waterloo end. The lights burned with apparently equal brilliancy as when short-circuited, and on the following day the length of the line was increased to 8815 feet, or 1.66 mile, but still without any perceptible effect on the light. We believe this is the longest circuit ever attempted to be used with an alternating current machine, and the success of the experiment has a very important bearing on the general question of electric lighting.

We have said before that the cost of a plant necessary for working twenty Jablochkoff lights is £990. The interest on this at 5 per cent would be £49 10s., and taking wear and tear at 10 per cent, £99, we get a total of £148 10s. Taking the whole time during which the lamps are lighted in the year at 3600 hours, say 10 hours a day, the cost of use of plant for each light per hour is 0.49d. To this we must add 3.24d. per light per hour for the cost of producing the light, and 2d. per hour per candle, making a total of 5.73d. per light per hour all the year round. Let us now compare the cost of gas with the latter figure. The light in the opal globe, as given above, is in round numbers equal to 155 candles, and in the granulated globe to 265 candles. To produce a light equal to 125 candles, one of the larger Sugg burners consumes 48 cubic feet of gas per hour, while to produce a 265-candle light we should require 83 cubic feet per hour. The cost of the former quantity of gas may be taken at 2d., of the latter at 3.5d., or, to put the matter more plainly,—

The cost of the electric light is ..	5.73 per hour.
Gas equivalent to electric light in	
opal globe	2.00 ..
Ditto ditto, frosted globe.. ..	3.50 ..

We have therefore, at last, a series of figures on this important subject which cannot possibly be doubted. The experiments which have yielded them have been carried out with the greatest care, and every precaution has been taken to render them so correct that all future cavil or controversy will be avoided; the practical outcome of the matter being that, used in the best possible manner, the amount of illumination in both cases being equal, the electric light costs $1\frac{1}{2}$ times as much as gas.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, May 24, 1879.

Prof. W. G. ADAMS, President, in the Chair.

New members:—Mr. R. Sedley Taylor, M.A., and Mr. Walter Emmott, A.S.T.E.

Mr. W. J. WILSON exhibited a new harmonograph and figures drawn by it. The figures drawn by prior harmonographs are all more or less imperfect, owing to loss of motion in the pendulums actuating the marking pen; and Mr. Wilson therefore designed a new harmonograph, which not only gives perfect figures, but admits of the phase of either of the two compounded motions being decreased by a known amount. In this instrument toothed wheels take the place of pendulums, the ratio of the teeth giving the ratio of the periods of the motions. By employing the device of an intermediate wheel gearing with two others, and arranging two or more wheels on the intermediate axle, a great variety of phase can be

obtained for each motion. An ingenious adjustment by means of a movable nut allows the phase of either or both motions to be altered to a known extent, and thus an endless variety of figures can be obtained. As in other harmonographs, a writing table, on which the paper is placed, and an aniline glass pen, are used. Several of the figures done also on glass were thrown on the screen, the stereoscopic effect being very apparent. In reply to a query, Mr. Wilson said that he had adapted some of the figures to the stereoscope.

Prof. HUGHES explained his new Induction Balance, and showed some of its principal effects. It is well known that on an electric current passing along a wire adjacent to another wire, an induced current is set up in the second wire in an opposite direction to the first or primary current. In the induction balance two primary circuits or coils are taken, with the same current (interrupted by a microphone acted upon by the ticking of a clock) running through both; and between these is placed a secondary circuit or coil in connection with a telephone. The primary coils are so wound as to oppose each others induction on the intermediate secondary. There is a point, moreover, between where these opposed inductive influences exactly neutralise each other. If the secondary coil be placed there, no induced ticking of the clock can be heard; but if the secondary be displaced to one or other side of this point, the ticking can be heard in the telephone, increasing in loudness as the secondary approaches one or other of the primaries. If the distance between the primaries be graduated into a scale, this contrivance becomes a sonometer, since it gives an absolute zero of sound and degrees of loudness. It is well adapted for measuring the hearing power of the ear, and when used for this purpose it is known as the audiometer. By splitting the secondary coil into two parts and placing each close to its proper primary, so that there are four coils in all arranged in two pairs, the extremes in one primary circuit and the means in one secondary, the two opposing parts of the balance can be separated from each other, so as not to disturb each others action, and the balance made very sensitive by the closeness of the primaries and secondaries. Prof. Hughes finds that there is a line or zone of maximum induction midway between each primary and its secondary. If a conductor, such as a piece of metal, be put in this position it has a maximum distributing effect on the balance, due probably to the electric currents generated in it by the induction. The effect is apparently proportional to the conductivity of the metal. It requires an exactly similar piece of metal put between the other pair of coils to restore the equilibrium of the balance. A very slight difference of alloy or of weight between two like coins is at once observed from the imperfect restitution of the balance; base coins are thus also at once detected. Again, it is possible for a person to tell what particular coin or coins are in one part of the balance by trial of the same coins in his part. When plates of non-magnetic metals are held vertical in the balance their distributing effect is nil; iron, on the other hand, gives its maximum effect at this position, because its maximum effect overbalances its electrical effect. Two pieces of iron may therefore neutralise each other as cores in an induction coil. Steel is easy to balance compared with soft iron. Zinc disturbs most when placed along the sides of each pair of coils; iron when in centre. A certain length of metal laid along the outsides of the coils produces silence. The maximum line of inductive force is midway between the coils, and there is a line of minimum force at half the thickness of each coil; a metal placed at these lines of minimum force has no disturbing effect on the balance. Pressure, torsion, heat, magnetism, strain, and in fact all imponderable forces, are indicated, and their effects may be measured.

Prof. W. G. ADAMS believed that one result of Prof. Hughes experiments will be the determination of the way in which the law of electro-dynamic induction depends on density. He also imagined that the metal

the maximum line between the coils gathered the lines of force to itself, whereas when on the minimum lines it could not thus divert them.

Prof. AYRTON cited the early experiment of Faraday with a sheet of copper oscillating to rest between two opposite magnetic poles. The copper took a long time to stop; but a sheet of iron placed between two like poles was soon stopped, owing to its becoming imbued with an opposite polarity, and deflecting the lines of force. He also suggested that the divergence of the results for conductivity of metals got by the induction balance from those got by the Wheatstone balance might be due to that electric inertia suspected by Sir William Thomson.

Prof. GUTHRIE thought that the induction balance pointed to the conclusion that the disturbing effect of a conducting mass applied in this way is proportional to the quantity of electricity generated in it under certain conditions of temperature, &c. The determination of the conductivity of liquids would be a useful application of the balance.

Mr. CHANDLER ROBERTS gave some results which he had obtained from an examination of certain alloys by means of the induction balance. He had been able to detect a difference of 1 part in 1000 in the amount of silver present in two shillings of equal weight. He also pointed out that Mathiessen divided alloys into three classes:—(1) Solidified solutions of one metal in another; (2) Solidified solutions of one metal in an allotropic modification of another metal; (3) Solidified solutions of allotropic modifications of both metals. For the first class the curve of electric conductivity is a straight line; for the second, a parabolic curve; for the third, a bent line. Mr. Roberts found that the balance gave the characteristic curve for the first class with an alloy of lead and tin, and for the second with an alloy of gold and silver. With a copper-tin alloy, which is a good example of the third class, he found the curve given by the balance to be intermediate between Alfred Rich's curve of density and Mathiessen's curve of conductivity, and considers that the balance is influenced by the density as well as by the conductivity of the metal interposed.

Prof. HUGHES said that as the working of metals appeared to effect their conductivity, he was inclined to rely more on the conductivity measurements of the balance than on those of the Wheatstone bridge. By the balance plain pieces of metal were taken, whereas by the bridge wires were mostly taken. He would rather not give any theories yet as to the results obtained from the balance.

Dr. ERCK then exhibited his novel Pump for lifting solutions out of batteries.

chemists, more remote. Besides this, the difficulty of hunting down a practical fact amongst a crowd of theories is avoided.

In the present issue the author has adhered more or less closely to the lines followed in the first edition, which was published in 1874. As then, he divides the elements and pseudo-elements into monads, dyads, &c.—an arrangement which greatly helps the memory. The chapter on Chemical Theory has also undergone the process of subdivision, and the matter has been greatly extended. The chapters on the Organic Compounds have also received large additions, and have also been relegated to the concluding chapters of the book instead of being classified according to their chemical constitution as in the first edition. This arrangement, though perhaps not very philosophical, is at any rate a convenient one for the hard worked medical or pharmaceutical student.

Two useful appendices have been added to the new edition: one showing the quantities of the various ingredients to be added in parts by weight to 100 parts of alcohol, to produce the different artificial fruit essences; the other, the relation between the density and flashing point of paraffin oils. These appendices will be of great use to the practical chemist, but why annex them to the theoretical division of the work?

The second volume of the work has been in a great measure remodelled and re-written. The processes employed by chemists are first described, beginning with solution and lixiviation, and ending with electrolysis and pyrology. The next chapter treats of the detection and separation of the metals used in pharmacy, and Chapter 3 follows with the detection and separation of the acidulous radicals. Chapter 4 gives the method of quantitative analysis as applied to the examination of the official salts—*official*, by the way, being the new and more correct epithet applied to what used to be called *official* preparations. The next chapter gives a course of quantitative analysis as applied to the detection of unknown salts, while Chapter 6 gives a complete course of alkaloidal analysis. The other chapters are devoted to toxicological analysis, volumetric and geometric quantitative analysis in general, ultimate organic analysis, and, lastly, special analytical processes, such as the analysis of potable water and cinchona bark, the valuation of opium, the estimation of emetine in ipecacuanha, the alcoholic strength of spirits, wines, and tinctures, and the analyses of urine and urinary calculi.

Mr. Joseph Ince has again done good service to Dr. Muter by undertaking the tedious—but, as far as his students go, certainly not the thankless—task of compiling copious indexes to both volumes, which will greatly add to the value of Dr. Muter's already valuable work.

NOTICES OF BOOKS.

An Introduction to Pharmaceutical and Medical Chemistry (Theoretical and Descriptive), arranged on the principle of the Course of Lectures as delivered at the South London School of Pharmacy. Second Edition. By Dr. JOHN MUTER, M.A., F.C.S., &c. London: Simpkin and Marshall. 1879.

An Introduction to Analytical Chemistry, &c. Second Edition. By Dr. JOHN MUTER, M.A., F.C.S., &c. London: Simpkin and Marshall. 1879.

Dr. MUTER has done well to divide the second edition of his "Pharmaceutical and Medical Chemistry" into two separate volumes. The first part, being almost purely theoretical in its character, is intended to be for perusal at home, while the second half, being purely practical, is to be used in the laboratory. Besides obviating the inconvenience of dragging a heavy book backwards and forwards from the study to the laboratory, the division of the Manual into two parts will render the possibility of spoiling an expensive work, by the accidents common to all

Report on the Air of Glasgow, chiefly relative to Enclosed Spaces and Smoke. By W. J. DUNNACHIE, in co-operation with the Medical Officer of Health. Presented to the Committee of Health of the Magistrates and Council of Glasgow. May, 1879.

It is found that the proportion of atmospheric sulphur reaches its annual minimum in July, and, as might be expected, is highest in the central stations. Nitrogen, in the forms of actual and potential (albuminoid) ammonia, has two periods of excess, one in the summer and one in the winter. It appears, from Mr. Dunnachie's experiments, that these two forms of ammonia are largely derived from the combustion of coal, &c., and are consequently no absolute indices of the sanitary condition of the air. This fact has scarcely received sufficient attention on the part of sanitary chemists. Even Dr. R. A. Smith, in his classical work on "Air and Rain," though fully admitting the presence of tarry distillates in the atmosphere, still says "the ammonia is one measure of sewage of air not purified." Dr. J. B. Russell observes that "the methods of Pasteur and Pouchet, of Cohn and Lister, are necessary to give precise meaning to the work of Angus Smith

and other chemists in the region of air, and of Wanklyn and Frankland in the region of water." The guidance of chemical analysis is not absolute and all-sufficient; but as the most dangerous impurities, whether of air or of water, appear to be not merely organic, but organised, it must be controlled and supplemented by biological inquiry. This, however, neither Dr. Angus Smith nor Prof. Frankland will, we think, dispute.

Proposed Legislation on the Adulteration of Food and Medicine. By E. R. SQUIBB, of Brooklyn. New York: G. B. Putnam's Sons.

THIS pamphlet comprises the draft of an anti-adulteration law for the State of New York. It includes definitions of food, of medicine, and of the offence of adulteration, the various phases of which are illustrated by examples. The penalty for a first offence is a fine not exceeding two hundred dollars, and for further convictions imprisonment with hard labour for a term not exceeding six months. The Act is to be worked by a State Board, composed of two physicians, one chemist and physicist, one lawyer, and one "business man."

The author gives an abstract of English legislation on the adulteration question, and a history of their working. Here he speaks of analysts who "took the initiative, bought their own samples for analysis, and entered upon prosecution where necessary." This is a misapprehension. A public analyst who should act in this manner would be gravely overstepping his duty.

CORRESPONDENCE.

MANUFACTURE OF SULPHURIC ACID.

To the Editor of the Chemical News.

SIR,—I was pleased to note in the *CHEMICAL NEWS*, vol. xxxix., p. 226, only just to hand, that Dr. Lunge qualifies the favourable opinion on the use of liquid nitric acid, given on his authority in Lock's work, lately published, on the manufacture of sulphuric acid; for, I confess, I was somewhat surprised on reading the book, to find that, with his extended practical experience, he should advocate a process which entails expenses in the shape of labour, fuel, and maintenance of extra plant, as well as unavoidable loss and waste. After undertaking the management of these works I seized the first opportunity of setting up two large Daglish's nitre pots, and to discard the nitric acid stills. The result is a saving of 1½ per cent of saltpetre on the 100 tons pyrites burnt weekly. The requisite quantity of nitre is weighed out twice daily to the chamber foreman, and is proportionately charged into the pots once every hour.—I am, &c.,

JOHN COX.

Chemische Fabrik "Colombia,"
Mülheim-a-Rhein, May 26, 1879.

EXPLOSIONS IN FLOUR-MILLS.

To the Editor of the Chemical News.

SIR,—Will you allow me, in reply to Mr. Arthur M'Dougall's letter, briefly to state that my letter on the above subject appeared in the *Glasgow Herald* immediately after the explosion in the Tradeston Flour Mills; in fact, I believe, about a couple of days after the sad accident. It was noticed in a brief leading article on the subject as the most likely solution of the mystery, and after Dr. Stephenson Macadam's paper appeared (which was considerably afterwards), the Scottish Royal Society appointed a commission of inquiry into the subject, together with the question of priority, the upshot of which was

that I received a private letter from the Secretary, Dr. Ferguson, of Edinburgh, which I still have, in England), in which my prior claims were fully acknowledged, and I was informed, too, that my report or letter to the *Glasgow Herald* was framed as the first. Dr. Macadam was mentioned, too, as having been the first to invite a scientific investigation to the theory I brought forward, and so to support it further. Still, I must conscientiously acknowledge that the brain which to the best of my knowledge deserves the fullest credit of the conception is that of the Austrian chemist, whose name I have forgotten, but whose little notice in *Dingler's Journals* supplied me with the necessary light on the subject, which I did but endeavour to spread and throw upon that fatal catastrophe at Glasgow. Mr. M'Dougall's letter will be welcomed as a very interesting contribution, and I feel no doubt he is right as to the abolition of the stove-room. With regard to the inconvenience of small electric lights disposed over a flour-mill, I cannot judge, not having experience in the matter. It is for the mill-owner to decide which inconvenience is greater, that of ordinary lights, with the chance of explosions; or the electric lights, with safety. I fancy the filtration of the air, as Mr. M'Dougall suggests, may prove a difficult matter; but I wish it all success, as it would doubtless remove the danger. Still, it is always to be remembered that from abnormal causes and accidents, the air may sometimes even then become laden with flour dust in certain rooms or parts of the mill, and a vivid flash might communicate itself where an ordinary flame or light would fail to do so.—I am, &c.,

WATSON SMITH, F.C.S., F.I.C.

Zürich, June 1, 1879.

DR. PAVY'S METHOD OF DETERMINING GLUCOSE.

To the Editor of the Chemical News.

SIR,—It was only a few days ago that my attention was drawn to the article by Mr. Otto Hehner in the *CHEMICAL NEWS* (vol. xxxix., p. 197) on the ammoniated cupric liquid proposed by me for the quantitative determination of sugar. I am glad to find that so able a chemist as Mr. Hehner has conducted an inquiry into the merits of the test, and it is satisfactory to notice that with a proviso regarding the amount of alkali employed he is able to speak of the method as "capable of furnishing excellent results."

At the outset of his investigations Mr. Hehner obtained results which stood at variance with mine, and considerably paid a visit to my laboratory at Guy's Hospital to see in what manner the discordancy was to be accounted for. Upon being informed of his mode of procedure, which consisted in using 100 c.c. of the test-liquid, and dropping the saccharine solution in slowly throughout the process, instead of employing only 20 or 40 c.c., and running the liquid in rapidly from the burette until near the point required, and then proceeding slowly—a difference which leads to the operation being much more prolonged in the one case than in the other, it immediately occurred to me that the discordancy arose from the test-liquid failing to resist the influence of the prolonged boiling, and that this would probably be rectified by the employment of a larger amount of alkali. I have found with Fehling's solution that its stability under ebullition is impaired by dilution unless an additional quantity of alkali is put into it. I suggested to my assistant, Mr. Scard, who has ably worked under my direction in this matter, that more alkali should be used, and it was found that the true explanation of the discordancy had been hit upon. Without further concert than I have mentioned, the idea also occurred to Mr. Hehner to try the effect of a larger quantity of alkali, and when an interview took place a short time afterwards each learnt that an accord had been arrived at.

In my communication to the Royal Society I stated that with the test proposed, 1 atom of sugar appropriated

6 atoms of oxide of copper instead of 5 as is the case with Fehling's solution used in the ordinary way. I further mentioned that potash might be added to the extent of 1 grm. to 20 c.c. of the ammoniated test without altering the result, but that with the addition of 5 grms., or anything beyond, 5 instead of 6 atoms of oxide of copper were appropriated by 1 atom of sugar, and with quantities of added potash between the 1 and 5 grms. the results stood between the 5 and 6 atoms of oxide of copper. Mr. Hehner, in commenting upon this, says that his observations, which he has verified over and over again, show that a much smaller excess of soda influences the result than is stated by me. Mr. Hehner seems not to have noticed that the added alkali in my observations consisted of potash instead of soda, which he employed. The difference in the atomic weights of the two alkalies will nearly suffice to account for the difference existing in our recorded results.

For many years past the liquid which has been used in my laboratory as a sugar-test has been made with potash instead of soda, and has contained nearly double the equivalent of the soda existing in Fehling's solution. I was led to introduce the larger amount of alkali because it appeared to me that the liquid possessed greater stability and precision of behaviour. I am now using this liquid not only as formerly, but also for the preparation of the ammoniated solution, and it contains a sufficient amount of alkali to serve for what is required. The quantity of copper is the same as in Fehling's solution. The two liquids therefore possess the same quantitative value. The composition is as follows:—

Cupric sulphate.	34.65 grms.
Potassio-sodic tartrate (Rochelle salt)	173 "
Potash	160 "
Water to 1 litre.	

For the ammoniated test 120 c.c. of this solution are mixed with 300 c.c. of strong ammonia (sp. gr. 0.880), and water is added so as to make up to a litre. The test, being in this form a 6-atom instead of a 5-atom oxidising liquid, it is of 1-20th the value in relation to sugar indication of the original solution, or 20 c.c. correspond with 0.010 grm. of glucose.

On account of the liability of the cupric sulphate to impurity it is preferable, where great accuracy is required, to use electrolytic copper. The quantity of copper to be taken is 8.808 grms. This is dissolved in nitric acid and evaporated to dryness after the addition of sufficient sulphuric acid to secure that a sulphate is left. The product is then dissolved in water and neutralised with potash. In this way the exact amount of cupric sulphate is supplied that is required to yield a solution of the standard strength.

I originally recommended, for preventing the atmosphere from becoming charged with the evolved ammonia, that a U-shaped tube containing fragments of moistened pumice-stone should be used. I find that a much more simple and convenient contrivance for attaining the object is afforded by carrying a piece of vulcanised tubing from the flask into a beaker or other vessel containing water. The end of the vulcanised tubing intended to dip into the water is plugged at the extremity, and just above the plug provided with a transverse slit through three-fourths of its extent. This admits of the escape of air and ammoniacal vapour from the flask, but precludes by its valvular arrangement the sucking back of water from the occurrence of any sudden condensation in the interior of the flask.

Uric acid exerts a reducing action upon oxides of copper equally as precise as glucose. The quantitative determination of it has hitherto constituted a lengthy and not very satisfactory process, but I find that with the ammoniated cupric liquid its determination may be easily and speedily effected. A large number of observations have been conducted in my laboratory with the view of ascertaining its precise reducing capacity, and the results so closely conform with the expression that 3 atoms of oxide of copper are reduced by 1 atom of uric acid that I am led

to give this as the relation existing. I am not aware that the extent of reducing action of uric acid upon the oxide of copper has hitherto received attention, and I should be glad to learn if the conclusion I have mentioned is confirmed by the observations of others.—I am, &c.,
F. W. PAVY.

May 30, 1879.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 17, April 28, 1879.

The Electric Light.—J. Jamin.—The burner submitted to the Academy with its points downwards has considerable advantages; such as simplicity, since it requires no mechanism and requires no preliminary preparation, beyond a support and the coke points; mechanical economy, since the number of flames is almost doubled; augmentation of light, since each of the new foci is almost twice as powerful as those of the old construction; quality of the light, which is whiter; more advantageous arrangement of the foci, which direct their greatest quantity of light downwards, where it is wanted, instead of up into the air, where it is useless; and, lastly, economy of combustible material.

Electric Inscription of Words.—M. Boudet de Paris.—The transmitting apparatus is a microphonic speaker, the carbons of which, instead of being pressed by a spring, are simply maintained in contact by the pressure of a small piece of paper folded in form of a V. The vibrations of the diaphragm of the receiving apparatus cannot be written, since the movements of the style, however delicate the apparatus, can scarcely be distinguished upon the lamp-black. To enlarge the magnetic vibrations of the receiver the cover and the diaphragm of a Bell's telephone are taken away, and on the wood of the instrument there is fixed the end of a small stiff steel spring. The other end of the spring abuts on the surface of the magnetic nucleus surrounded by its coil; to this extremity is soldered a small mass of soft iron, weighing about 10 grms., and upon this mass and in the produced line of the axis of the spring is fixed a light style of bamboo, 10 centimetres in length and terminating in a slender whale-bone pen.

Theoretic and Experimental Demonstration of the following Definition of Temperature; the Temperature is Represented by the Length of the Calorific Oscillation of the Molecules of a Body.—R. Pictet.—A mathematical paper, not capable of useful abstraction.

A Siren with an Electro-magnetic Regulator.—M. Bourbouze.—By means of this instrument sound can be made to pass from 8162 vibrations per second, through all the intermediary notes to 128 vibrations.

The Laws of Dissociation.—MM. Moitessier and R. Engel.—The dissociation of a body both whose components are volatile takes place even when the body is placed in presence of one of the products of dissociation, so long as the tension of this product does not surpass the dissociation-tension of the body at the temperature of the operation. When the tension of one of the components is greater than the dissociation-tension of the compound the dissociation no longer takes place. Two cases may then arise; either the dissociable compound is volatile, and in that case the true vapour density may be determined, or else the dissociable body is not volatile, as is the case with chloral hydrate at 60°. When two gaseous products on combining form a dissociable com-

pound the combination only takes place when the sum of the tensions of the components exceeds the dissociation-tension of the compound.

Determination of Glucose in Blood.—P. Cazeneuve.—A reply to the criticisms of MM. d'Arsonval and Picard (*Comptes Rendus*, 1879, pp. 753 and 755).

Contributions towards the History of Beer-yeast and of Alcoholic Fermentation: Physical and Physiological Action of Certain Substances, Saline or otherwise, upon Normal Yeast.—A. Béchamp.—Yeast which has undergone the influence of sodic acetate, and which has been well washed and drained, can no longer be as completely fluidified by a new addition of acetate. Yeast, after a first treatment with the acetate, and whilst still impregnated with this salt, is still capable of undergoing fermentation. Yeast which has been, after two or three treatments with acetate, deprived of the greater part of its soluble matters is nevertheless capable of setting up energetic fermentation in cane-sugar.

No. 18, May 5, 1879.

Certain Derivatives of Durol (α -Tetra-methylbenzol).—MM. Friedel, Crafts, and Ador.—The authors have obtained a compound, which may be named phenyl-duryl-carbonyl, if we give the name duryl to the monatomic residue of durol, from which 1 atom of the hydrogen of the benzenic nucleus has been removed. At the same time there is formed another compound, almost insoluble in boiling alcohol, duren-dicarbonyl-diphenyl or duren-dibenzoyl, which, if treated at a boiling heat with melting potassa, is resolved into benzoic acid and durol.

Crystals extracted from Cast-iron by means of Ether or Petroleum.—J. Lawrence Smith.—On treating comminuted cast-iron with these solvents, on the spontaneous evaporation of the liquid, the author obtained acicular crystals consisting principally of sulphur, and absolutely similar to those extracted by the same process from meteoric iron. M. Berthelot, to whom the author had forwarded specimens of the crystals, stated that he had obtained similar bodies by the action of pure ether upon octahedral sulphur and upon anhydrous iron sulphides. It thus appears that even neutral solvents do not in all cases act by simple solution upon the bodies with which they come in contact, but effect also a chemical alteration.

Effects of Carbonic Sulphide upon the Radicular System of the Vine.—M. Boiteau.—The author concludes that this agent in doses of 6 to 10 grms. destroys by poisoning all the parts of the root system which are within a radius of about 10 centimetres of the point where it is applied. This action is produced in the parts situate from 20 to 35 centims. below the surface. He still recommends the use of this sulphide, applied at a distance of more than 10 centims. from the main root.

Thermic Formation of Hydrogen Silicide.—J. Ogier.—The heat disengaged in the combustion of 1 equiv. of this compound is 324.3 cals., and the mean heat of its formation is 24.8 cals.

Limit of the Separation of Alcohol and Water by Distillation.—J. A. Le Bel.—The greatest degree of concentration obtained by repeated rectifications was 96.5 per cent. On rectification over quick-lime an alcohol of 98.5 was produced. When this spirit was submitted to fractional distillation the water passed over first, and the residue was the most highly alcoholic. After three rectifications the first portions marked 97.4 and the residue 99.3. The author finds that amylic alcohol from wines has not the repulsive odour of fusel oil or of the crude amylic alcohols of (beet-root) treacle. This odour, and possibly the injurious physiological action of the higher alcohols, may possibly, he considers, be due to the presence of certain empyreumatic compounds.

A New Isomer of Angelic Acid.—E. Du villier.—

The author has obtained iso-angelic acid along with ethyl-oxy-valeric acid on causing the bromo-iso-valerate of ethyl to act upon the ethylate of sodium in an alcoholic solution.

Transformation of Camphic Acid into Camphor.—J. de Montgolfier.—On heating calcic camphate and formates together the author obtained camphor, well characterised by its composition and properties, and accompanied by camphren, an isomer of phoron.

No. 19, May 12, 1879.

The Vision of Colours, especially the Influence exercised upon the Vision of Coloured Objects in Rotatory Motion when Observed Comparatively with Identical Bodies in a state of Rest.—E. Chevreul.—This is a somewhat diffuse extract from a recent work by the author, and does not admit of useful abstraction.

Bases Derived from Aldol-ammonia.—A. Wurtz.—Ammonia, when reacting upon aldol, gives rise to various bases, whose nature varies according to the conditions of the experiment. At 100° there are formed certain oxygenous bases soluble in water, the study of which is still incomplete. At 140° to 180°, and in presence of an excess of ammonia, dark-coloured oily bodies are formed, soluble in ether. A mixture of liquid and volatile bases is obtained on submitting aldol-ammonia to dry distillation in a current of ammoniacal gas.

Effects of Inhaling Oil of Turpentine.—M. Poincaré.—The author has examined 282 workmen who use this oil in their trades, and has kept animals for several months in a medium strongly charged with its vapour. Among the workmen the symptoms were headache, dizziness, watery eyes, weakness of sight, especially in artificial light, cough, and troubled digestion. In most cases the constitution became habituated to this agent, but sometimes a change of employment was necessary. The animals experimented upon remained in a normal condition if good ventilation was maintained. In confined air death ensued in consequence of congestion of the brain, lungs, &c.

Two Applications of the Method of MM. Fizeau and Foucault.—M. Mouton.—A mathematical paper not suitable for abstraction.

Thermic Researches upon Silicic Ether.—J. Ogier.—The mean heat of formation of silicic ether is -11.5 cals.

Action of Ammoniacal Salts upon Certain Metallic Sulphides, and Application of the Facts Observed to Mineral Analysis.—Ph. de Clermont.—Bismuth, cadmium, and copper sulphides are not affected if boiled with a solution of sal-ammoniac, as is also the case with mercurous and mercuric sulphides. Antimony trisulphide is completely decomposed by sal-ammoniac, yielding antimony sulphide, which escapes, and antimony chloride, which remains in solution. Stannic sulphide yields stannic acid and no tin dissolves. Stannous sulphide is similarly decomposed, leaving stannous oxide. Metals not thrown down by hydric sulphide from their acid solutions, but converted by ammoniac hydrosulphate either into sulphides or insoluble oxides, after the action of this reagent, behave in a peculiar manner with sal-ammoniac. It is already known that manganese sulphide dissolves as chloride. Iron sulphide in the same manner gives iron chloride. Nickel and cobalt sulphides dissolve likewise, though more slowly. Zinc sulphide resists longer, but ultimately dissolves also. Alumina and chromic oxide precipitated by ammoniac hydrosulphate are known to be insoluble in sal-ammoniac. On these reactions the author founds a method for the separation of certain metals. If a solution contains cobalt, nickel, manganese, iron, alumina, chrome, and zinc, it is precipitated with ammoniac hydrosulphate, the mixture added to a boiling solution of sal-ammoniac, and kept in ebullition for a sufficient time. On filtering, which is effected rapidly, the filtrate contains all the iron and manganese, part of

the cobalt, nickel, and zinc, whilst the undissolved portion contains all the alumina and chrome with the residue of the nickel, cobalt, and zinc. The analysis is completed by known methods. If iron and manganese alone have to be separated from alumina and chrome the process is complete and precise.

New Formation of Glycocoll by means of Nitro-acetic Ether.—M. de Forcrand.—Nitro-acetic ether yields glycocoll on reduction with tin and hydrochloric acid.

No. 20, May 19, 1879.

A New Derivative of Nicotin.—A. Cahours and A. Etard.—The new base, to which the authors assigned the name thio-tetra-pyridin, has a composition represented by $C_{16}H_{18}N_4S_2$.

Transparence of the Media of the Eye for the Ultra-violet Rays.—J. L. Soret.—The author concludes that the absorption of the totality of the media of the eye must render it impossible to perceive rays whose refrangibility exceeds that of the extreme radiations of the solar spectrum, say the ray U.

Preliminary Researches on the Action of Acids upon Salts without the Intervention of a Solvent.—M. Lorin.—The direction of the results indicates chemical action more or less distinct, and which, for the fatty acids, decreases from formic acid to each of its successive homologues.

Presence of Mercury in the Mineral Waters of St. Neaire.—E. Willm.—The author's results have been mutually contradictory. Supposing mercury to be a constant element of the water the quantity shown by his only affirmative experiment falls far short of that resulting from the analysis by Dr. Garrigon.

The Mode of Combination of Iron in Hæmatoglobulin.—L. Jolly.—The author concludes from his analyses that iron occurs in the blood-globules merely as phosphate.

Bulletin de la Société d'Encouragement pour l'Industrie Nationale.

No. 64, April, 1879.

Report presented by M. Ed. Collignon on the Electric Brake of M. A. Achard.—The moment that an electric circuit is broken, whether by the separation of a part of the train, by carriages getting off the line, or by fire, the wheels are automatically locked.

Report by M. Sebert on the Electric Bells of M. Laville.—The arrangement of this apparatus cannot be made intelligible without the aid of the accompanying illustration.

Revue Universelle des Mines, de la Metallurgie, &c.,
Tome 4, No. 3, November and December, 1878.

Explosions Caused by Dust.—This paper recounts the facts laid before the Société d'Encouragement by Prof. Lawrence Smith in November, 1878, and the discussion on the same subject at the Academy of Sciences.

No. 1, January and February, 1879.

Relation between the Temperature of the Earth and the Depth below the Surface.—P. Van Dijk.—The author draws the following conclusions:—The increase of the geothermic scale proves that the earth is engaged in a continual process of cooling. This increase corresponds to the law of the refrigeration of a spherical body, having a uniform elevated initial temperature. The degree of cooling differs much for different parts of the earth's surface, according to their geographical and thermological position, and exercises an important influence on

the vertical distribution of underground heat in any place. The loss of heat which the earth incessantly undergoes, from its surface being infinitely small, compared with the quantity stored up within, a large part of the earth's interior must still possess a very high temperature. The real geothermic progression, as accessible to human observation, far from indicating a minimum thickness for the earth's crust, imposes, on the contrary, a very narrow limit on the maximum temperature of the earth's interior. By the abstract application of this progression we should be led to ascribe to the earth's centre a heat not exceeding 100° . Actual facts observed, however, cannot be more simply explained than by the reaction of an igneous or fused nucleus, of a crust of considerable thickness, and having little conductivity for heat. The thickness of the earth's crust is very unequal, probably three times greater in the polar regions than in the volcanic regions of the Equator, and in one and the same latitude greater beneath the sea than on dry land. The greatest differences of thickness for one and the same latitude are met with in countries where, with an elevated mean temperature at the surface, the alternation of dry land and deep sea is most frequent. The volcanic character of the Eastern Archipelago agrees with this conclusion. According where the terrestrial crust is thinnest a temperature of 3000° will be found at the depth of 21 geographical leagues, not more than 1-40th of the earth's radius. In the polar regions it is probably more than four times as thick.

Biedermann's Central-blatt.

Heft 3, March, 1879.

Preparation of Artificial Animal Charcoal.—Th. Filter.—The author proposes to obtain a cheap form of gelatin by treating leather waste mixed with from 1 to 5 per cent of caustic soda with steam at a pressure of six atmospheres in closed iron vessels. The resulting semifluid mass is placed in a centrifugal, which keeps back the gelatin whilst tannate of soda runs off. So much of this jelly as is equal to 33 kilos. of dry glue is mixed with 50 kilos. bibasic phosphate of lime and 17 kilos. phosphate of magnesia. The mass is submitted to strong hydraulic pressure between layers of felt, dried at 110° , and ignited in the ordinary manner.

Occurrence and Life of Bacteria and their Influence upon Yeast.—MM. Schnetzler, Bretefeld, Downes, Blunt, and Gunning.—Light is hostile to the development of bacteria and microscopic fungi. The exclusion of oxygen occasions the death of bacteria, but promotes putrefaction.

Reimann's Färber Zeitung,
No. 16, 1879.

Tartar Emetic in Dyeing.—The author points out that tartar emetic, as used in cotton-dyeing, serves not to fix the aniline colours themselves, but merely to fasten the tannin, thus playing the part of an indirect mordant. Several experiments have been instituted at the Färber Akademie in order to ascertain whether this application of antimony can be pronounced injurious to public health. It was found that water, in which cotton yarns dyed with aniline colours on a mordant of tannin and tartar emetic had been steeped, or especially boiled, gave distinct indications of antimony when tested in ordinary manners. The quantity of the metallic compound fixed on the fibre seems, indeed, far too trifling to have any effect upon human health. Still, in view of the panic which has seized upon the public mind, and of the tendency of the literary and political press to attribute all mysterious attacks of sickness to the influence of poisonous dyes, &c., Dr. Reimann—in our opinion very judiciously—advises dyers to dispense with the use of antimony, which will doubtless be found by no means necessary.

No. 17, 1879.

This issue is mainly taken up with the specification of F. V. Kallab's patent process for bleaching animal fibre with hydrosulphurous acid.

Chemiker Zeitung.

No. 16, April 17, 1879.

Inflammability of Petroleum.—The first part of a paper on the possible sources of error in testing petroleum, and the precautions needful for obtaining comparable results.

Poisonous Colours.—The Association for the Protection of Chemical Industry, in Germany, has petitioned the Reichstag that no colour shall be condemned as dangerous until it has been duly examined by a Commission of specially qualified chemists and physiologists.

Dr. Volhardt succeeds to the chair of the late Prof. Gorup-Besanez, at the University of Erlangen.

Properties and Chemical Examination of Tea.—Dr. J. M. Eder.—The author holds that one-half of all tea sold is sophisticated with spent tea-leaves. He places no confidence in the determination of thein as a test of the genuine character of tea, but proposes to ascertain total extractive matter as obtained with hot water; proportion of tannin in the decoction; total ash; proportion of ash soluble in water.

Starch in Filter-paper.—The *Beyer Industrie-Blatt* cautions chemists against errors which may be produced by this impurity.

Gold in Petroleum.—According to the *Bergmann* Mr. J. Turnbridge has extracted 34 dollars' worth of gold from a ton of the residues from petroleum-stills. The source of the petroleum was not ascertained.

Salubrine-Cenosote.—This name has been employed by M. Perrot, of Geneva, to a mixture of salicylic acid and tartar, which he recommends as a preservative for beer, wine, &c.

A Curiosity of Patent Literature.—A specific for the teeth, patented in Belgium, consists of 950 parts water, 12 parts urea, 0.4 part uric acid, 7 parts of fixed salts, and 8.90 of urate, oxalurate, oxalate of lime, cystin, &c.—a composition which agrees wonderfully well with that of urine. A little perfume has been added. (Is this a new way out of the sewage difficulty?)

No. 18, May 1, 1879.

According to the *Repert. de Pharmacie* magenta has been successfully administered in the treatment of albuminuria, to the extent of half a gramme daily.

Les Mondes, Revue Hebdomadaire des Sciences.

No. 15, April 10, 1879.

Origin of Lactose.—There appears to exist in the mammary glands during lactation a lactogenous substance, which, however, differs widely from the other glycogens. M. Schützenberger is engaged with its chemical examination.

Quantitative Analysis of White Light.—Prof. Rood divides the spectrum into twelve parts, and, multiplying the space occupied by each part by the relative luminous intensity, he obtains the following numbers:—Red, 54; orange-red, 140; pure orange, 80; orange-yellow, 114; yellow, 54; greenish yellow, 206; yellowish green, 121; green and greenish blue, 134; Prussian blue, 32; blue, 40; violet, approaching to ultramarine, 20; pure violet, 5. Hence the quantity of light in the so-called warm colours is three times greater than that in the cold colours. This division of the spectrum does not seem to rest upon any demonstrable basis, and the author has not been guided by the spectral lines.

No. 16, April 17, 1879.

Reduction of the Cost of the Electric Light.—M. Delaurier.—By preventing all access of atmospheric air the duration of the carbon points is increased ten-fold, and the working cost is reduced by two-thirds.

Physiological Action of Benzol.—M. Bensch.—The author shows that benzol, which has been proposed as an anæsthetic, acts as a poison if inhaled as vapour or introduced into the circulation.

Spectroscopic Optics.—M. Moigno, in translating Prof. Piazzzi Smyth's lecture on "End-on Illumination," points out that he has been to some extent anticipated by Dr. van Monckhoven (*Les Mondes*, 1877, p. 177).

No. 1, May 1, 1879.

This issue contains no original chemical or physical matter.

No. 2, May 8, 1879.

Universal Support, or Electro-diapason for Representing Vibratory Movements and showing them in Projection.—A. Dubosc.—This memoir cannot be intelligibly abstracted without the addition of the five accompanying plates.

No. 3, May 15, 1879.

An international subscription is proposed to erect a monument to Nicéphore Niepce, at his native town, Chalon-sur-Saône.

The new freezing machine of M. D. L. Holden, of Philadelphia, is, in sum, that of M. Piçet, somewhat varied in form.

The electric bit is applied very successfully to vicious horses by the Omnibus Company of Paris.

MISCELLANEOUS.

Mineralogical Society of Great Britain and Ireland.—A general meeting was held at 116, Victoria Street, London, S.W. (Prof. P. G. Bonney in the chair), on Tuesday, June 3rd. The election of fourteen corresponding members, eight ordinary members, and two associates was announced. The following papers were read:—"On Abriachanite, a new Scottish Mineral," by Prof. M. F. Heddle and Dr. W. Aitken; "On Haughtonite, a new Mica," by Prof. M. F. Heddle; "On Bheekite and Xantholite from Scotland," by Prof. M. F. Heddle; "On Christophite from St. Agnes, Cornwall," by J. H. Collins, F.G.S.; "Minerals from Japan," by John Milne, LL.D.; "On some Gold Occurrences," by the Rev. J. Clifton Ward, F.G.S.; "Additional Note on Penwithite," by J. H. Collins, F.G.S.; "Measurements of the Angles of Basaltic Columns at the Giant's Causeway," by Profs. Jellett and O'Reilly.

MEETINGS FOR THE WEEK.

MONDAY, 9th.—Royal Geographical, 8.30.

TUESDAY, 10th.—Royal Institution, 3. "The Intellectual Movement of Germany from the Middle of the Last to the Middle of the Present Century," Prof. Hillebrand.

— Photographic, 8.

SKELETON NOTES on ANALYTICAL
CHEMISTRY for STUDENTS in MEDICINE.

By ALBERT J. BERNAYS,
Professor of Chemistry at St. Thomas's Hospital Medical College
Examiner in Chemistry at the Royal College of Physicians.

By the same Author, Sixth Edition, fcap. 8vo., 3s. 6d.

NOTES for STUDENTS in CHEMISTRY:
A Syllabus.

London: J. and A. CHURCHILL.

NEW EDITION OF MUTER'S CHEMISTRY.

Just published in two Vols. as follows:—

Vol. I.—AN INTRODUCTION TO CHEMISTRY (Theoretical and Descriptive). Second Edition. 400 pp., royal 8vo., price 10s. 6d.

Vol. II.—AN INTRODUCTION TO ANALYTICAL CHEMISTRY. Second Edition. 216 pp., royal 8vo., with copious tables and concise instructions for the qualitative and quantitative analysis of metallic salts, alkaloids, water, &c., price 7s. 6d.

This well-known work, although specially designed for pharmaceutical and medical students, will be found very useful to all commencing the study of general chemistry, the novel principle on which they are arranged ensuring a rapid and comprehensive grasp of the subject by the learner.

London: Published by W. BAXTER at the Office of the South London School of Pharmacy, Kennington Cross, and sold by Messrs. Simpkin and Marshall and Messrs. Baillière, Tindal, and Cox, and at all booksellers.

PATENTS.—Mr. Vaughan, F.C.S., British, Foreign, and Colonial PATENT AGENT. Special attention given to Inventions relating to Chemistry, Mining, and Metallurgy "Guide to Inventors" Free by Post.—Offices, 67, Chancery Lane London, W.C., and 8, Houndgate Darlington.

Advertiser, with Six Years' Experience in Analytical Chemistry, desires an Engagement as Assistant or as Chemist in Works. No objection to go abroad.—Apply, H.H., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Practical Man desires a Situation as Foreman in Chemical or Artificial Manure Works. Understands the management of mechanics and labourers; also construction and maintenance of plant, chambers, manure making, &c. Good references.—Apply, H. G., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

LABORATORY.

Wanted, a Working Assistant for the Manufacturing Department of a Pharmaceutical and Chemical Laboratory in London. Applicants not answered in ten days may be considered declined.—Apply by letter to H. H., 66, Queen Street, Cheapside, E.C.

Wanted, by a Chemist of Nine Years' experience in Tar Products, a Situation as Manager or Chemist in a Tar Works. Is practically acquainted with the business, and has a thorough knowledge of the products derived from coal-tar, especially the refining of anthracene and the manufacture of artificial alizarin.—Address, X. Z., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO CHEMISTS AND DRUGGISTS.

The Shop, 140, Leadenhall Street (in which a Chemist's Business has been successfully carried on for nearly 180 years), to be Let on 21 years Lease (in consequence of existing Tenants retiring from business), with possession on July 10, 1879. For further particulars apply to Messrs. Jones, Lang, and Co., 5, King Street, Cheapside, E.C.

FOR SALE.

Oertling's Balance in good order; nearly new set of weights; agate pestle and mortar; twelve Bunsen burners, with roses, and copper water-ovens. Price £18.—Enquire, R.S., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and Co., Clayton, near Manchester.

W. E. BUTT & CO.,
UNION CHEMICAL WORKS,

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1020.

NOTES ON THE CHRONOLOGY OF THE ISOMERIC PURPURINS, AND THE ACTUAL RELATIONS OF THE BODIES WHICH HAVE BEEN CALLED BY THE NAMES ANTHRA-PURPURIN, ISO-PURPURIN, AND FLAVO-PURPURIN.

By HENRY MORTON, Ph.D.,
President of the Stevens Institute of Technology.

THERE is a piece of recent chemical history which has already become much involved on account of the oversight of some writers, and as the threads happen to be in my hands, I think I shall do a good office to future students by laying these out straight at the present time.

In 1870 Mr. W. H. Perkin published in the *Journal of the London Chemical Society* a paper entitled "On Artificial Alizarin" (vol. viii., p. 143), in which at the end, in a footnote, the author says—"When purifying artificial alizarin by converting it into an alumina lake, I found that upon digestion with carbonate of potash this lake gave a red-coloured solution containing a colouring matter, dyeing mordants very similarly to alizarin, with this difference, that the reds are more scarlet and the purples bluer or more slaty. I have not obtained this body in a perfectly pure state as yet, but it appears to be crystalline."

The investigation thus opened by Perkin was diligently prosecuted by him, and at the meeting of the London Chemical Society, held June 6, 1872, he read a paper on this body, an abstract of which paper is published in the *CHEMICAL NEWS* (vol. xxv., p. 284), and a fuller report of which appears in the *Journal of the London Chemical Society*, vol. xxv., p. 659, under the title "Note on a Secondary Colouring Matter Produced in the Preparation of Alizarin from Anthracen." In these publications he gives the formula of the new body as $C_{14}H_6O_5$, and notes its relations and differences to and from the purpurin of madder. In the next volume of the *Proceedings*, or rather *Journal of the Chemical Society*, viz., vol. xxvi., 1873, Perkin published on page 425, under the title "On Anthrapurpurin," a long article on the same substance, to which were attached, as illustrations, pieces of cloth dyed with the substance as well as others dyed with alizarin. This article has been translated and quoted extensively in other publications, but the other articles seem to have been overlooked or forgotten. Hence have arisen some of the errors which I now propose to correct.

From the above references it will be seen that Perkin first separated out and recognised this new body in 1870, and diligently following up the research, published its formula in the beginning of June, 1872, and a full and exhaustive memoir in 1873.

In the *Moniteur Scientifique* for August, 1872, or just two years after the first publication by Perkin, and just two months after his second, in which he gave the formula of his new substance, appeared a communication announcing the discovery of a new product extracted from artificial alizarin by G. Auerbach, and named by him isopurpurin.

No mention whatever was made in this article of Perkin's prior publication, and it was of course generally inferred that Auerbach knew of them, but regarded his isopurpurin as a new discovery of his own, and not a mere confirmation of Perkin's work. In the course of time it appeared, however, that this was not the case, but that Auerbach

was ignorant of Perkin's prior publications, and, believing his material to be the same as that more fully described by Perkin in 1873, claimed priority.

Into this error he seems to have led several writers. Thus, Graebe and Liebermann, in their report on Artificial Alizarin at the Vienna Exhibition, under the heading isopurpurin, refer first to Auerbach's publication in the *Moniteur Scientifique* of August, 1872, and then to Perkin's third publication in the *Journal of the Chemical Society* of 1873, omitting all reference to, and evidently not knowing of, his earlier publications in 1870 and June of 1872.

Rosenstiehl, in a recent article, has fallen into a like error, and credits Auerbach with first obtaining this body in an impure state, and Perkin with having first extracted it pure in 1873.

But admitting that Auerbach is right in assuming that what he extracted was only the anthrapurpurin of Perkin, it is evident that he has no claim whatever to priority, but that the substance must be credited to Perkin, and should be called by his name of Anthrapurpurin.

As a matter of fact, however, the substance actually extracted by the method described by Auerbach in 1872 is not anthrapurpurin, but a mixture consisting largely of a substance which was new at that time, but was afterwards isolated by Messrs. Schunck and Roemer.

My reasons for this opinion are the following:—In the latter part of 1874 I had occasion, together with my friend Mr. Wm. E. Geyer, B.S., to repeat both Perkin's and Auerbach's method of treatment upon considerable quantities of artificial alizarin. We first followed out Perkin's method, and obtained a product corresponding in all respects with his description of anthrapurpurin. We then worked on another quantity of artificial alizarin according to Auerbach's directions, and when we came to the last treatment, namely, solution in and crystallisation from alcohol, we found that we evidently had to do with a mixture of two bodies differing in a marked way as to their solubilities.

Bearing in mind that we had found Perkin's anthrapurpurin but little soluble in alcohol, and that Auerbach described his isopurpurin as quite soluble, we so carried on the alcohol treatment as to reserve the soluble part as isopurpurin and reject the less soluble portion.

When we had carried this separation to a sufficient extent, we found that we had a body entirely distinct from Perkin's anthrapurpurin, but sufficiently like the description given by Auerbach of his isopurpurin to answer for it when due allowance was made for the uncertainties of a verbal description. When, however, the paper of Schunck and Roemer appeared in 1875, we saw that the body we had extracted agreed still more closely with their flavopurpurin.

Having obtained it, however, by the process described in 1872 by Auerbach, I still continued to call it by his name, and should do so still had he not very emphatically repudiated all credit for and connection with it.

The true relation of the substances which have borne the names given at the head of this article is, then, this:—

Anthrapurpurin is a single substance, first isolated by Perkin, partially in 1870, and thoroughly prior to June 6, 1872.

Isopurpurin is a mixture, in proportions varying according to the composition of the artificial alizarin from which it is extracted, and the way in which the alcoholic treatment is conducted, of anthra- and flavopurpurin with a trace of alizarin. This mixture was first separated and described by G. Auerbach in August, 1872.

Flavopurpurin is a single substance or chemical individual first isolated and described by Schunck and Roemer in the *Ber. der Deut. Chem. Gesell.*, 1876, p. 678.

The facts as to the composition of the material obtained by treating artificial alizarin by the method described by Auerbach are also established by the recent researches of M. A. Rosenstiehl, presented to the Chemical Society of Paris, and published in the *Bulletin* of that body of May 5 and 20, 1878, where, in vol. 29, p. 408, I find as follows:—

"On submitting isopurpurin obtained by the method described by M. Auerbach to proximate analysis, I was not slow in discovering the presence of 15 per cent of alizarin." Here follows a long and minute description of how this was removed by treatment with hot benzol.

The material so purified was then dissolved in boiling alcohol, and allowed to deposit crystals on cooling. The author then continues:—

"Comparative dyeing tests with the part crystallising out and with that remaining in the mother-liquor showed that the alcohol eliminated a substance colouring mordants like flavopurpurin, that is to say, of a red more orange than that of oxanthraflavon."

It should be mentioned that in this essay its author indicates by the word oxanthraflavon the material isolated by Perkin's method, but which through oversight of the earlier publications he credits to Auerbach, and names isopurpurin in consequence of this mistake.

ON THE COMPOUNDS OF THE TERPENES WITH HYDROCHLORIC ACID.

By WILLIAM A. TILDEN.

IN the course of researches which I have for some time been pursuing into the constitution of the terpenes I have had occasion to prepare and examine the compounds which these hydrocarbons form with hydrochloric acid. The following is a brief account of the chief results arrived at in this direction, and as they possess some interest at the present time, I think it desirable to place them on record.

When dry hydrochloric acid gas is passed into cooled turpentine oil (b.p. 156°), whether from American or French turpentine, the well-known mono-hydrochloride, $C_{10}H_{17}Cl$, is obtained, melting at 125°, and boiling at about 210°. It is accompanied by liquid products, which yield a large quantity of the same hydrochloride on distillation. This liquid consists of a mixture of cymene, always present in turpentine oil, with liquid compounds of the mono-hydrochloride and di-hydrochloride. The fact that the two chlorides when mixed together unite and liquefy was originally pointed out by Berthelot, and I can confirm this observation. The existence of a liquid modification of the mono-hydrochloride is doubtful. The solid mono-hydrochloride is also produced if the turpentine is diluted with benzol or carbon bisulphide before submitting it to the action of the gas.

The result is different when the turpentine is saturated with hydrochloric acid in the presence of some liquid which contains water, or is capable of yielding the elements of water. Thus, when the same turpentine oil is diluted with alcohol, ether, or glacial acetic acid, it yields a deep purplish coloured liquid, which, after exposure to the air for some time, deposits crystals of the di-hydrochloride, $C_{10}H_{18}Cl_2$. But it deserves to be noticed that when once the terpene has been made to unite with one molecule of hydrochloric acid no further action of the gas, either in the dry state or in presence of any of the solvents named, is capable of causing it to combine with a second molecule so as to produce the di-hydrochloride. There can be no doubt that these two chlorides are of entirely dissimilar constitution, as they behave quite differently under the influence of alkalies, the mono-hydrochloride being decomposed with difficulty by soda, yielding a crystalline camphene, whilst the di-hydrochloride produces chiefly terpinol, $C_{10}H_{17}(OH)$. The di-hydrochloride referred to possesses the same properties, whether prepared from lævo- or dextro-rotatory turpentine oil. Its solution in alcohol is optically inactive. The crystals melt at 48° in an atmosphere of hydrochloric acid, and by heat are readily decomposed into hydrochloric acid and a hydrocarbon. This di-hydrochloride is also obtained by the

action of hydrochloric acid gas upon crystallised terpin hydrate and upon terpinol. (*Journ. Chem. Soc.*, June, 1878.)

If in place of turpentine oil one of the terpenes of higher boiling-point is operated upon no mono-hydrochloride can be obtained. Thus, the terpene from orange oil boiling at 176° was dried and saturated with hydrochloric acid. The resulting solution was colourless, and after exposure to the air for a day or two was found to contain no chlorine at all. But when the same terpene was mixed with ether, and treated with the gas, a solid mass of colourless crystals remained after evaporation of the ether. It was a somewhat unexpected discovery that these crystals consist of the same di-hydrochloride already described, that is obtained under the same circumstances from turpentine. There is, however, some difference observable in the behaviour of the terpene from the orange and those from the turpentine oils; for whilst the former yields a nearly theoretical amount of crystallised di-hydrochloride, the latter produce a considerable quantity of liquid of deep colour. This colouration is characteristic of the action of hydrochloric acid upon terpinol, $C_{10}H_{18}O$, or $C_{10}H_{17}OH$, as shown in a recent paper (*Journal of the Chemical Society*, June, 1879), and it appears to indicate the formation of an intermediate product which is probably the same in both cases.

In order further to establish the identity of the di-hydrochlorides thus obtained from the two classes of terpenes, the dichloride prepared from the orange oil and from turpentine oil were decomposed by water. 50 grms. of each boiled with 500 c.c. of water were found to be decomposed at the same rate and in the same manner, yielding a mixture of hydrocarbon (terpinylene, $C_{10}H_{16}$, b.p. 176°), and terpinol ($C_{10}H_{18}O$, b.p. 210°). The terpinol was recognised in each case by its conversion into crystallised terpin by the action of sulphuric acid and water. The terpenes from juniper oil (b.p. 156°), lemon (b.p. 176°), bergamot (b.p. 176°), and caraway (b.p. 176°) yield this di-hydrochloride, as also does the terpene (b.p. 174° to 176°) contained in the *ol. pini sylvestris* of pharmacy and a terpene (b.p. about 176°), obtained from rosin spirit.

The single exception is the "sylvestrene" discovered by Atterberg in Swedish turpentine, and which I have since recognised in Russian turpentine. The di-hydrochloride which this terpene yields melts at 72° to 73°, and although decomposed by alkali it yields a hydrate which is apparently not common terpinol. If it should prove to be distinct from ordinary terpinol it is probable that it may be convertible into a new terpin. I am about to make experiments with the object of settling this question, which possesses some interest.

The terpene di-hydrochloride described in this paper is decomposed by simple application of heat, and by prolonged boiling in a flask fitted with condensing tube is resolved into hydrochloric acid and a hydrocarbon, terpinylene, $C_{10}H_{16}$, which boils at 176°. A portion of the hydrocarbon is at the same time converted into viscid polymers. Terpinylene cannot, however, be made to recombine with hydrochloric acid so as to reproduce the crystalline di-hydrochloride.

Thus terpenes of the two classes, boiling respectively at 156° and 176°, and very diverse in their optical properties, may all, by this process, be converted into one and the same inactive hydrocarbon.

I cannot conclude without expressing my thanks to Mr. G. H. Morris and Dr. G. Harrow for valuable assistance in these experiments and in other parts of the same research.

The Paris Academy of Sciences.—At the sitting of the Academy on Monday last Professor G. G. Stokes, M.A., D.C.L., LL.D., Secretary of the Royal Society, was elected a corresponding member in the Physical Section in succession to the late M. Angström.

ON NITROGEN IODIDE.

By J. W. MALLET.

THE various researches upon the highly explosive black substance formed by the action of iodine upon ammonia have, as is well known, led to different views of its composition. That first put forward by Colin and Gay-Lussac, namely that it is nitrogen tri-iodide, appeared to have been set aside by the experiments of Serullas,* Millon,† Bineau,‡ Gladstone,§ Playfair, and Bunsen,|| all of whom found hydrogen to be a constituent, but in varying amount, the formulæ $\text{NH}_3\text{I}-\text{NH}_2\text{I}-\text{NH}_3\text{I}$ and $\text{NH}_3\cdot 4\text{NI}_3$ having been assigned to the products obtained by somewhat different processes, until more recently Stahlschmidt¶ has revived the statement that under certain conditions at least the simple tri-iodide is formed.

One source of error in the analysis of this instable compound seems to have received insufficient attention from some of those who have examined it, and somewhat affects the conclusions drawn from the experiments of others. The substance, obtained as a black powder by the action of iodine on ammonia, decomposes gradually in contact with water, nitrogen gas being slowly evolved, iodine liberated, and iodic and hydriodic acids or ammonium salts formed. This decomposition takes place to no inconsiderable extent during the drying of the powder at ordinary temperature, and may be readily proved to have occurred by treating the dry residue with any of the solvents for iodine, as for instance alcohol, chloroform, or carbon di-sulphide, which at once form deeply coloured solutions. Hence the air-dried powder is really a mixture of the original substance or substances with various decomposition products, and so is unsuited for accurate analysis. On the other hand, it might be doubted in regard to the analyses made of freshly prepared and still moist iodide, whether the results apply to a substance capable of being obtained in the dry state without decomposition.

Millon and Bineau, it is true, seem to have aimed at guarding against this difficulty by drying the materials, side by side with solid potash, under a jar of gaseous ammonia. Bineau remarks that some of the gas is at first absorbed by the water moistening the powder, but that as the drying proceeds the gas recovers ("à peu près") its original volume, and that so moisture is gotten rid of without the iodide being decomposed. But, without qualitative examination of the gas, or a very accurate determination of its volume, this does not afford satisfactory proof that the dry substance is unchanged. I have observed continuous, though slow, evolution of little bubbles of nitrogen from the freshly prepared powder when kept under strong aqueous ammonia, though in this case no free iodine can be found, since as fast as it is liberated it reacts with the excess of ammonia, reproducing the nitrogen iodide, and forming more ammonium iodide, which latter therefore tends to accumulate in the liquid, and is thus to be found in the residue from drying up a moist mass of the powder in an atmosphere of ammonia.

I have applied a different method, which is often useful under other circumstances, for quickly getting rid of water, namely repeated and rapid washing with absolute alcohol, followed by ether, and final evaporation of the last-named volatile liquid.

20 or 30 grms. of iodine was dissolved in a minimum of 95 per cent. alcohol, and precipitated by pouring into a large volume of cold water. The finely divided iodine was washed several times by decantation, then gently triturated for several minutes in a porcelain mortar with

a large excess of the strongest liquid ammonia kept at or below 0°C . by a freezing mixture, the liquid poured off from the easily subsiding black powder, and replaced two or three times by fresh solution of ammonia. The powder was then at once transferred to a corked flask, and shaken up repeatedly, first with alcohol of 95 per cent., then with absolute alcohol, and finally with anhydrous ether, all of these liquids being artificially cooled. Most of the last portion of ether, which, as well as several of the preceding washings, was perfectly colourless, having been decanted off, the fluid black mud was turned out upon a filter, drained in a few moments, and the remains of the ether swept away as vapour by placing the filter and contents under a receiver and drawing cold dry air through in a rapid stream. This use of alcohol and ether to remove water from the iodide after its formation is not to be confounded with the employment by several experimenters of alcoholic solutions of iodine or ammonia, or both, in making the substance in the first instance.

The product thus obtained was explosive in the highest degree, yielding to very slight friction upon paper, frequently producing a crackling sound from little partial explosions when it was gently rubbed under water, and in two instances exploding in some quantity under water, with much violence and complete shattering of the vessel.

The relative quantities of nitrogen and iodine were ascertained by decomposing an unweighed parcel of the substance by a moderately strong aqueous solution of sodium sulphite, neutralised by dilute sodium hydrate, and determining, in equal volumes of the liquid, the nitrogen as ammonia (expelled by boiling with excess of soda, and collected in sulphuric acid of standard strength), and the iodine as silver iodide.

A—In three experiments were obtained—

I	267.12	264.27

or, for 1 atom of nitrogen—

Atoms of iodine ..	2.10	2.08
--------------------	------	------

Of the above results—

A distinctly represents the atomic ratio N:I=1:3, fully confirming Stahlschmidt's conclusion that the tri-iodide can be obtained quite free from hydrogen.

B corresponds well with N:I=2:5, and

C with the proportion found as the result of several earlier experiments, N:I=1:2.

If B be admitted to stand for a definite compound, and not a mere mixture of A and C, which is rendered probable by the fairly close agreement of the results obtained with the calculated figures, there must be two atoms of nitrogen in the molecule, and the formula will be N₂HI₃. This formula may almost as well be deduced from Bunsen's analysis of one of the products he obtained (by addition of ammonia to a solution of iodine in nitro-hydrochloric acid, diluted with water, and rapidly washing with cold water) as that which he has himself assigned, viz., NH₃.4NI₃, since the figures stand—

	Calc. for N ₂ HI ₃ .	Calc. for NH ₃ .4NI ₃ .	Found by Bunsen.
N 4.22	4.38 ..	0.008143 or assumed 4.38	
H 0.15	0.19 ..		
I 95.63	95.43 ..	0.174417	93.82*
100.00	100.00		

It will be seen that the figures of the formula now proposed differ less from those of Bunsen's formula than the latter do from the results of experiment.

In view of the general fact that the compounds of nitrogen in which this element behaves as a pentad are those in which instability is chiefly observable, and noticing the various proportions in which the iodine and hydrogen have been found together united with it, it seems fairly probable that the molecule of each of these explosive compounds contains two pentad nitrogen atoms; and reviewing all that has been published on the subject, with attention to the sources of error connected with the various methods used, we seem to have established the following series of substituted products, beginning with the tri-iodide:—

Experiments of Stahlschmidt (using aqueous ammonia) and those now reported (A).

Experiments of Bunsen (second product), and above result (B).

Experiments of Bineau, Stahlschmidt, Gladstone (using alcoholic solutions of ammonia and iodine), and above result (C).

* There seems to be an error in the calculation of the percentage of iodine in the original paper (*Ann. d. Ch. u. Pharm.*; 84; 1), but the figures here given are correctly deduced, I believe, from the actual weighings quoted, viz., 0.1300 grm. of ammonio-chloride of platinum and 0.0732 grm. of palladium.

Experiments of Bunsen (first product, using anhydrous alcoholic solutions of ammonia and iodine). He himself assigned the formula NH₃.NI₃.

It is much more doubtful whether we should add—

Experiments of Milon (in 1838). The product dried under a receiver filled with gaseous ammonia had lost its extreme explosiveness, and no doubt contained ammonium iodide.

It appears that, not only may these different products be obtained by varying the conditions under which the formation of the explosive substance is effected, but during its decomposition by water, certainly involving more than a single series of reactions, one of these products may be more or less converted into others.—*American Chemical Journal*.

University of Virginia, Feb. 21, 1879.

ON THE SOFTENING OF MAGNESIA-HARD WATER.

By J. GROSSMANN, Ph.D.

I HAVE lately had an opportunity of making some experiments on the softening of so-called magnesia-hard water by Clark's process. Although from a theoretical point of view there is no reason why such water should not be softened as easily as ordinary (lime-)hard water, it was thought convenient to try the experiment on a somewhat large scale, especially as I have not been able to find that any experiments on the softening of magnesia-hard water have been published before in detail.

The water in question is pumped from a colliery at Collins Green, near St. Helens. The bottom of the well is about 96½ yards from the ground, and I give for completeness sake the different strata, as well as the quantity of lime and magnesia per hundred, which hydrochloric acid dissolved out of them, the samples being previously dried at 240° F.

	P.c. CaO.	P.c. MgO.	Yards.
Depth of alluvium and clay from surface of ground to top of the red sandstone	—	—	17
New red sandstone	0.16	0.24	34
Yellow sandstone	0.10	0.22	13
Compact red sandstone	4.72	0.37	12
New marl or metal	2.16	0.52	6
Dun Rock	0.40	0.46	1
Coarse porous red sandstone ..	1.88	0.27	13
Coarse red sand	0.72	0.32	1
			96½

This water is organically very pure and contains only small quantities of chlorides and sulphates. The hardness is almost entirely temporary, though in estimating the permanent hardness it is sometimes difficult to remove the lime and magnesia by boiling. I may as well point out in this place a common fallacy, which is that hard water by being boiled before being used for domestic purposes becomes soft. As it is generally only heated to boiling just before being used for washing or cooking it makes not much difference in the hardness of the water. The following is taken from the Sixth Report of the Commissioners appointed in 1868 to inquire into the best

means of preventing the pollution of rivers. Thirteen samples of water drawn on thirteen different days from the kitchen boiler of a dwelling-house, and from that of the Athenæum Club, were found to be usually nearly as hard as the cold water with which those boilers were supplied, as is seen from the following results:—

Hardness of Cold Water.	Hardness of Hot Water.	Hardness of Cold Water.	Hardness of Hot Water.
14.6	13.6	15.4	14.3
14.4	13.9	15.9	11.9
14.4	13.4	16.1	11.9
14.6	11.6	18.7	18.4
14.6	7.6	18.7	18.6
14.4	11.7	18.7	18.4
14.4	12.1	—	—

I boiled Collins Green water that tested 27.8° total hardness in an ordinary tea-kettle for five minutes, and even that exceptionally temporary-hard water tested then still 17.6° total hardness. The experiments for softening this water by Clark's process were made in two series; in the first milk of lime was used, and in the second lime-water. The milk of lime was prepared by mixing 5 lbs. of slaked lime of 70 per cent CaO with 6 gallons of Collins Green water. In performing the softening of the water the milk of lime was gradually added to the water during the operation, the mixture being well agitated during the whole experiment.

In three experiments the hardness was reduced from 23.3° which the water tested originally to 5.0°, 5.5°, and 5.7°. The total solids were reduced respectively from 33.9 to 13.0, 33.6 to 12.2, and 33.6 to 13.6 grs. per gallon. The softened water, after it had been standing in stoppered bottles for a few days, formed a little deposit, and its hardness was then 3.5° in all cases. The analysis showed that then the lime had been reduced from 9.13 to 1.62; the magnesia from 5.23 to 0.23 grs. per gallon.

There were used on an average 1465 gallons of water to 3.5 lbs. of CaO, corresponding to 2.67 lbs. of lime of 90 per cent per 1000 gallons. Theoretically to precipitate the lime and magnesia as far as I have done in my experiments would require 2.31 lbs. of CaO per 1000 gallons.

The experiments for softening with lime-water were carried out in a similar way. A measured quantity of the lime-water was put into the mixing tank, and the Collins Green water run into it until nearly all the lime of the former was taken up, which in these experiments as well as in those with milk of lime was ascertained by the well known silver test. The mixture was well agitated during the whole experiment. A great advantage in working with lime-water is that it requires less agitating than working with milk of lime.

In four experiments the hardness was reduced from 23.3°, which the water tested originally, to 3.5°, 3.3°, 3.5°, and 3.5°. The total solids were reduced respectively from 34.3 to 12.0, 34.4 to 11.2, 34.6 to 12.0, and 34.7 to 11.2. The lime had been reduced from 9.07 to 1.67, and the magnesia from 5.24 to 0.18 grs. per gallon.

There were used on an average 1670 gallons of water on 530 gallons of lime-water, which latter having been exposed to the air for some time before being used tested only 60 grs. CaO per gallon. This corresponds to one volume of lime-water of 60 grs. CaO per gallon to 3.13 volumes of Collins Green water, or corrected to 90 grs. of CaO per gallon, which strong lime-water should contain, the proportion of lime-water to Collins Green water would be 1 to 4.72. This result is not quite correct, as the lime-water had undergone a further susceptible decomposition while lying in the mixing-tank; so that at the time of its action on the Collins Green water it contained less than 60 grs. CaO per gallon. Both in working with milk of lime and lime-water the softened water settled perfectly clear after three to five hours, taken from the time that the agitation was suspended.

From these experiments it follows that magnesia-hard

water softens as well and as easily by Clark's process as ordinary (lime-)hard water.

I wish to point out here that in my opinion, with our present knowledge of the behaviour of magnesia-hard water towards soap solution, the hardness test in cases of water of that description cannot be relied on in any way. Mr. Wanklyn, in his book "On Water Analysis," says that magnesia takes up as much soap as 1½ equivalents of lime would take up. If that were so the Collins Green water should have tested 35.9° total hardness, instead of 23.3°, which it gave on the most careful testing. It will be noticed that this is even less than the water would require if it contained an equivalent of lime for the magnesia present; for the calculated hardness would then be 29.4°. It appears to me that in the case of magnesia-hard water a determination of the lime and magnesia is the only means of showing the quality of the water. On the other hand, I quite agree with Mr. Wanklyn in putting little reliance on the distinction between temporary and permanent hardness, unless the estimations have been performed very carefully; and there are cases in which, even with the most careful working, figures for temporary and permanent hardness may be got which are not trustworthy.

ANALYSIS OF THE WATER OF ST. DUNSTAN'S WELL, MELROSE.

By WILLIAM JOHNSTONE, F.C.S., F.I.C.

An exhaustive analysis of this strongly ferruginous saline carbonated water has not, so far as I have been able to learn, been published before, although a general analysis of it was made by Mr. J. Dewar in 1870, and published in the CHEMICAL NEWS, vol. xxiv., p. 171. There has been a partial analysis of this water also by Dr. Stevenson Macadam, of Edinburgh, but as his results are very doubtful I refrain from quoting it at all. As this water is peculiar for the large quantity of iron it contains, and as its composition seems to have varied considerably since it was examined by Prof. Dewar, it is thought that another and more complete analysis will not be out of place.

Melrose is a village of some 2000 inhabitants, and is situated at the base of the Eildon Hills, in the valley of the Tweed; one of those lovely spots that are said to be particularly favourable to the curative effects of medicinal waters. The surrounding country consists principally of richly variegated fields, and the entire district teems with objects of natural beauty, while every spot on which the eye rests is associated with some incident of historic or classic interest—the ecclesiasticism and chivalry of the past, and the interest conferred by Scott in the present. The salubrity of the district is well known, and the romantic scenery, which is equalled by few places in the kingdom, presents a picture dear to the lover of nature as well as to the invalid.

The spring, which belongs to Mr. John Turnbull, of St. Dunstan's Cottage, Melrose, was accidentally discovered in 1870, when sinking a shaft for ordinary spring water. The water is said to be uniform in quantity, its temperature varies only within very narrow limits, and is quite cold. As it occurs in the spring it is perfectly clear, of a yellowish colour, but, after exposure to the air, deposits the iron as a ferric manganic oxide; it has a strong powdery odour and a decided inky taste. When taken from the well there is a disengagement of small pearly bubbles, and on being shaken up in a closed bottle liberates a large quantity of gas. The temperature of the spring on October 5, 1878, was 50° F., the temperature of the air at the same time being 62° F. The specific gravity of the water is 1.0019356. A careful qualitative analysis indicated the presence of the following constituents in estimable quantities:—

Bases.	Acids, or Elements replacing them.
Soda	Chlorine
Potash	Sulphuric acid
Lithia	Phosphoric "
Ammonia	Carbonic "
Lime	Silicic "
Magnesia	Crenic "
Baryta	Apocrenic "
Strontia	Bromine "
Ferrous oxide	Iodine
Manganous oxide	
Alumina	

In addition to the above were found traces of fluorine, butyric and phosphoric acids, along with other volatile and non-volatile organic matter.

The residue of 30 gallons was examined by means of the spectroscope for caesium, rubidium, and thallium, but the search proved unsuccessful. The method of quantitative analysis employed was essentially that described by Fresenius under the head of "Analysis of Mineral Waters" in the last edition of his "Manual of Quantitative Analysis."

The following figures represent grammes per litre, and are the average of three determinations of each of the principal constituents, done in order to guard against error and to ensure accuracy; the amount of water taken for the several determinations was, whenever practicable, ascertained by weight.

Results of Analysis.

Chlorine	0'378243
Bromine	0'000305
Iodine	0'000788
Sulphuric acid (SO ₃)	0'074258
Carbonic dioxide (total)	0'682183
Silicic acid	0'035286
Ferrous oxide.. .. .	0'328680
Lime and strontia expressed as carbonates	0'103842
Magnesia (total)	0'056216
Lime precipitated as carbonate on boiling.. .. .	0'028544
Baryta	0'002917
Strontia	0'000886
Manganous oxide	0'000785
Phosphoric acid	0'020085
Alumina	0'006582
Lithia	0'000282
Potash	0'006258
Soda.. .. .	0'343063
Ammonia	0'018652

Total fixed constituents 1'390000

Following the arrangement adopted by Fresenius on the assumption that the strongest acids are united with the strongest bases, &c., and allowing for the fact that the more or less degree of the solubility of the salts decidedly influence the manifestation of the affinities, and in order to simplify reference and comparison, and by way of contrast, I append the results calculated as grammes per litre. (See next column.)

Gases dissolved in the water and expelled by ebullition *in vacuo* measured at 59° F. and 760 m.m. barometer.

	Cubic centims.
Carbonic dioxide	101'434
Oxygen	6'793
Nitrogen	31'250

139'477

I am unable at present to form an opinion as to whether the composition of the water is constant, owing to the surface-water having had free admittance to the well previous to the collection of this sample on March 18, 1879,

Barium sulphate	0'004441
Strontium sulphate	0'001571
Calcium sulphate	0'088017
Magnesium sulphate	0'030377
Magnesium bromide	0'000397
Magnesium iodide.. .. .	0'000945
Potassium chloride	0'009900
Lithium chloride	0'000463
Ammonium chloride	0'040985
Sodium chloride	0'544276
Magnesium chloride	0'027528
Aluminium phosphate	0'019503
Calcium phosphate	0'012511
Calcium carbonate	0'028544
Magnesium carbonate	0'037205
Ferrous carbonate.. .. .	0'529553
Manganous carbonate	0'001278
Silicic acid	0'027866
Crenic acid	0'013572
Apocrenic acid	0'000487

Total ingredients calculated 1'420519

but at the same time I may mention that a considerable sum of money has been expended in the view of preventing any more surface-water entering the well, so hope at some future date to be able to favour you with another analysis.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Thursday, June 5, 1879.

Mr. WARREN DE LA RUE, President, in the Chair.

AFTER the transaction of the usual business the following certificates were read for the first time:—E. Buckney, R. E. Holloway, T. Blackburn, E. F. Mondy, E. Francis. It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society (June 19).

The following papers were read:—

"A Contribution to the Theory of Fractional Distillation," by T. E. THORPE. Wanklyn some years ago found that when two liquids of different boiling-points were mixed together in equal quantities by weight and distilled, the proportion of each constituent in the distillate was the product of its vapour-density and vapour-tension at the temperature of ebullition of the fraction. Hence, under certain circumstances the less volatile of the two substances may pass over most rapidly, whilst if the vapour-tensions and vapour-densities of the two liquids are inversely proportional the mixture will distil unchanged. Berthelot observed that a mixture of 90'9 parts of carbon disulphide with 9'1 parts of ethyl alcohol boiled and distilled as a homogeneous liquid. An instance of this phenomenon has been noticed by the author. A mixture of equal volumes of carbon tetrachloride boiling at 76'6°, and of methyl alcohol boiling at 65'2°, was distilled. It was found that 46'5 per cent of the whole boiled constantly between 55'6° and 55'9°, 10° lower than the boiling-point of the most volatile constituent. This mixture contained 78'1 per cent carbon tetrachloride and 21'9 per cent methyl alcohol. This proportion, 3'6 to 1, is almost identical with that obtained by multiplying the vapour-tensions of the two liquids at the temperature of the boiling-point of the mixture (55'7°) by their respective vapour densities, $487'4 \times 15'97 : 372'4 \times 76'69 :: 1 : 3'67$. The distillation of the residue in the flask was continued by Mr. C. C. Starling: at first principally carbon tetrachloride, finally pure methyl alcohol passed over. The author suggests as a striking lecture experiment the following:—Three baro-

meter tubes are filled with mercury. Into one some methyl alcohol is passed; into the second some carbon tetrachloride; into the third a mixture containing by volume 3 parts of methyl alcohol to 5 of carbon tetrachloride: the depressions of the mercury column are 80, 70, and 130 m.m. respectively. The author promises a further research on the physical peculiarities of this mixture.

"Preliminary Note on the Action of Organo-zinc Compounds on Quinons," by F. R. JAPP. When finely-powdered phenanthren quinon is gradually added to zinc ethyl, diluted with ether so as not to be spontaneously inflammable, a reaction takes place with evolution of gas. The orange colour of the quinon disappears: a whitish powder is formed, which sinks to the bottom of the liquid. On decomposing this product with an excess of alcohol, boiling, and filtering hot, transparent, faintly yellowish, rectangular plates were obtained, fusing at 77° , and having the formula $C_{18}H_{20}O_3$. This formula can be resolved into—

The compound $C_{16}H_{14}O_2$ has not yet been obtained pure; but the monacetyl derivative, $C_{16}H_{13}O_2(C_2H_3O)$, has been prepared and analysed; it fuses at 103° . The author refrains at present from discussing the constitution of the compound $C_{16}H_{14}O_2$, but suggests that these reactions may serve to distinguish quinons from double ketons. He intends, also, to study the action of organo-zinc compounds on other quinons and allied substances as dibenzoyl.

After some remarks by Dr. ARMSTRONG on the interest and probable bearing of the above reaction,

Dr. WRIGHT read a paper entitled "Third Report to the Chemical Society on Researches on some points in Chemical Dynamics (On the Curved Surfaces expressing the Relations between Time, Temperature, and Amount of De-oxidation of Copper Oxide by Hydrogen and Carbon Oxide)," by C. R. A. WRIGHT, A. P. LUFF, and E. H. RENNIE. This is a continuation of the previous reports by the authors on the subject. In the present paper a large number of observations have been made by reducing a uniform weight (1.15 grms.) of copper oxide (prepared by igniting pure copper nitrate) in narrow glass U-tubes heated to known and constant temperatures in vapour-baths: in some cases water and paraffin baths were employed fitted with Page's gas-regulator. Equable streams of hydrogen and carbonic oxide were obtained by bubbling the gas through a wash-bottle, the stream being adjusted by a screw-clamp, and counting the bubbles. The average rate was 12.5 c.c. per minute. By plotting out the results thus obtained in space with reference to three planes mutually at right angles, so that the distance from each plane represents, respectively, the time of exposure, the temperature, and the percentage loss of oxygen. Points are marked on curved surfaces, the sections of which, parallel to the three primary planes, represent respectively, the amounts of oxidation produced in given times at a constant temperature, the times required to produce given amounts of deoxidation at constant temperatures, and the amounts of deoxidation produced at given temperatures in a constant period of time. The paper was illustrated by tables, diagrams, and models of the curves thus produced, the mode of experimentation adopted being to determine for a constant temperature the amounts of deoxidation produced in varying times. At and above 160° in the case of hydrogen, and 130° in the case of carbonic oxide, the curious result was arrived at that the same mean curve is obtained whether the exposure be made all at once to a temperature for a time, T, or in periods of time t_1, t_2, t_3 , &c., which are together equal to T, provided that the interval between the periods is not too long (ten minutes). Below the above temperatures the deoxidation in an hour is greater than that produced in two consecutive heatings of half an hour each with an interval between. The curves obtained with hydrogen and carbonic oxide resemble each other in certain respects; their general cha-

rafter is that of a sigmoid. For a certain time there is no perceptible action; this time is the longer the lower the temperature. Reduction then commences languidly, quickly accelerating until a maximum of activity is reached, after which it diminishes until almost perfect deoxidation is effected. The maximum rate of action with hydrogen lies about 10 per cent (out of 19.74 per cent) of oxygen originally contained in the copper oxide, and about 7 to 8 per cent in the case of carbonic oxide. This apparently indicates that hydrogen passes through the outer and partially reduced surface of particles to their interior more readily than carbonic oxide. The following numbers illustrate the maximum rates of reduction attained, the gaseous currents being competent to remove 0.7791 per cent of oxygen (out of 19.74) per minute:—

Temperature.	Maximum rate with H. Per cent per minute.	Maximum rate with CO. Per cent per minute.
100°	—	0.135
118°	—	0.380
130°	—	0.480
160°	0.118	0.570
175°	0.220	—
184°	0.270	0.270
210°	0.490	—
256°	0.700	—

The higher the temperature the nearer does each curve approximate towards a limiting straight line, which would be attained did deoxidation commence immediately and go on at such a rate that all the hydrogen was converted into water, and the carbonic oxide into carbonic acid. The highest rates of reduction attained corresponded to a conversion of about nine-tenths of the H into H_2O , &c., of CO into CO_2 . From the curves it is evident that, *ceteris paribus*, to perform a given amount of deoxidation with hydrogen requires either a higher temperature or a longer time than with carbonic oxide. The existence of "a period of incubation" during which no action takes place, and the acceleration in the rate of action to a maximum, &c., shows that what has been termed "Chemical Induction" by Bunsen and Roscoe takes place in these cases to a large extent, dependent in amount on the temperature. From experiments now in progress this does not appear to be the case when copper is oxidised by hot air. A number of observations were made on the effect of varying the speed of the current of reducing gas and the weight of copper oxide used, with the general result that a more rapid stream or a smaller weight of copper oxide corresponds to an increased percentage of deoxidation, and *vice versa*. Heating the copper oxide just before use causes great irregularities in the action. A large number of observations were made by enclosing the copper oxide in sealed tubes filled with the respective gases, heating for different periods, and determining whether reduction had taken place or not; thus the following numbers were obtained. The times are perceptibly longer than those found in the corresponding U-tube experiments; in every case the time at any given temperature is less with CO than with H.

Temperature.	With CO, period of Incubation equals about—	With H, period of Incubation equals about—
160°	12 minutes	80 minutes
130	35 "	6 hours
118	$6\frac{1}{2}$ hours	12 "
100	7 $\frac{1}{2}$ "	28 "
83.84	11 "	180 "

Attempts were made to trace out curves illustrating the rate of reduction at various temperatures in atmospheres containing more reducing gas than would suffice to de-oxidise completely the CuO . The results were not very concordant, but indicated that the action here is still of the same kind; i.e., a period of incubation exists, after which action commences, reaches a maximum, and then falls off; in other words, chemical induction takes place whether the metallic oxide or the reducing gas be at any given momen-

in excess. In these experiments, too, either the time requisite to produce a given amount of action is less or the temperature is lower with carbonic oxide than with hydrogen. The paper, of which the above is but a brief extract, contains about 70 pages.

"On Fractional Distillation," by F. D. BROWN. The author considers the theory and formulæ involved in the process of distillation. He sums up as follows:—"The equation which represents the relation between the composition of the liquid and that of the vapour given off by it at a given pressure, together with that which represents the relation between the composition of the liquid and its boiling-point at the same pressure, contain all the experimental data which can be derived from the distillation, and form, together with the above formulæ, a complete history of it. If we can refer these relations to known laws we shall have arrived at an explanation of fractional distillation." The consideration of the distillation of mixtures divides itself into four heads—substances which are not miscible; substances which mix in all proportions but do not combine; substances which are soluble to a limited extent and do not combine; and substances which are mutually soluble and combine. The author then considers the researches of Magnus, Regnault, Pierre and Puchot, and A. Naumann as regards substances which do not mix. From these researches it was proved that the ratio of the molecules of the two liquids in the distillate is constant, and equal to that of their vapour-tensions at the temperature of distillation. The author has taken up the study of substances which mix in all proportions but which do not combine. The substances chosen were benzene and carbon disulphide. The composition of the mixture was ascertained by taking its density. These liquids expand on mixing; the greatest expansion occurs when the molecules of each are present in about equal numbers. In a series of thirteen tables the author gives the results of the fractional distillation of mixtures containing 61.95 per cent, 61.76 per cent, 70.86 per cent, 40.81 per cent, and 18.33 per cent of carbon disulphide respectively. The temperatures at which the fractions distilled, their weights and composition, and the composition of the liquid remaining in the still are given. The author exhibited some of the apparatus used in his researches.

In the discussion which followed, in which the President, Dr. Wright, Dr. Armstrong, and Mr. Friswell joined, there seemed some slight uncertainty as to the exact conclusions to be deduced from the author's experiments.

Mr. HOWARD pointed out that substances might dissolve in the liquid condition but not when in a state of vapour. Amylic alcohol would distil at 96° in the vapour of water, but the presence of a small quantity of ethylic alcohol would completely alter the composition of the vapour.

The two following papers were then read by the SECRETARY:—

"On Chlorstannic Acid," by J. W. MALLETT. A bottle containing a strong aqueous solution of stannous chloride, after standing for a year or two, deposited a transparent jelly-like substance of yellowish colour. This was washed and dried on a glass plate at the temperature of the atmosphere: it shrank up, cracked, and dried in fragments resembling gum arabic. Heated in a glass tube it evolved hydrochloric acid, leaving a white residue of stannic oxide free from chlorine. Its composition was SnO_2HCl , its constitution—

It formed salts with soda and ammonia. The author has not been able to reproduce this substance.

"On Indigo-purpurin and Indirubin," by E. SCHUNCK. Baeyer and Emmerling (*Ber. Deut. Chem. Gesell.*, iii., 514) described some years ago the formation of a red colouring matter with indigo-blue by the action of acetyl chloride, phosphorus trichloride, and phosphorus on isatin. This they named indigo-purpurin. Recently, Baeyer (*Ber. Deut. Chem. Gesell.*, xii., 457) describes another method of pre-

paring this colouring matter, and gives its properties. In 1856 the author read a paper (*Manchester Memoirs*, 2nd series, xiv., 181 to 237) and gave an account of a red colouring matter formed by the action of acids on indican, indigo-blue being formed. This colouring matter he named indirubin. Indigo-purpurin has all the properties of indirubin, and is, in fact, identical with it. The author therefore considers that the name indigo-purpurin should be abolished, and the original name indirubin retained.

The Society then adjourned to June 19, when a ballot for the election of Fellows will be taken, and the following papers read:—"On Gardenin," by Dr. Stenhouse and Mr. Groves; "On the Action of Sulphuric Acid on the Hydrocarbons of the Formula $\text{C}_{10}\text{H}_{16}$," by Drs. Armstrong and Tilden; "Researches on the Terpenes, Camphor, and Allied Compounds (Parts I. and II.)," by Dr. Armstrong; "Contributions to the History of Starch and its Transformations," by Horace T. Brown; "On the Boiling-points of certain Metals and Metallic Salts," by Dr. Carnelly and H. Carleton Williams; "On the Determination of Nitric Acid by means of Indigo," by R. Warington; "On Dry Copper-Zinc Couples and Analogous Agents," by Dr. Gladstone and Mr. Tribe; "Notes on the Purple of the Ancients," by R. Schunck.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 21, May 26, 1879.

Refraction of Dark Heat.—P. DESAINS.—The author has never met with lenses so constructed as to collect to the same focus rays both from the beginning and the end of the dark spectrum. The study of the cold rays of the dark spectrum may lead to rules for constructing such lenses. If it is possible in the dark spectra to follow and recognise one and the same group of rays, then, in spite of the differences between the refractive and dispersive powers of the substances used, the absolute value of the refractions experienced by dark rays of one and the same wave-lengths in different diathermanous bodies may be determined.

Chemical Researches on the Formation of Coal.—E. FREMY.—The author holds that there are several kinds of isomeric cellulose, constituting the skeleton of plants. Coal is not an organised substance. The vegetal impressions presented by coal are produced as in shales or other mineral matters. The chief substances contained in the cells of plants under the double influence of heat and pressure produce bodies having a great analogy to coal. The pigments, the resins, and the fats of leaves if submitted to heat and pressure yield compounds which approximate to bitumens. The vegetable matter which gave rise to coal has undergone firstly the peaty fermentation, the coal being then formed by a secondary transformation.

Fluorescence of the Salts of the Earthy Metals.—J. L. SORET.—The author has already pointed out the beautiful violet fluorescence of solutions of cerium sulphate and chloride elicited only by the extreme ultra-violet rays of the induction-spark, the solar rays not being sufficiently refrangible for its production. He has since found that the solutions of many salts of the earthy metals possess analogous properties. He enumerates lanthanum chloride, didymium chloride and sulphate; terbium, yttrium, erbium, ytterbium chlorides; phosphoric chloride; thorium sulphate; zirconium sulphate and chloride; aluminium and glucinium chlorides.

Determination of the Lengths of Heat-waves.—M. Mouton.—Not susceptible of useful abstraction.

Diffusion of Lithia and its Presence in Sea-water.—E. Marchand.—The author shows that as early as 1850 he demonstrated the presence of lithia in sea-water, more than fifteen years before the spectroscopic researches of M. Bunsen, to whom M. Dieulafoy had in a recent paper ascribed the first discovery of this alkali in the sea.

Salts of Guanidin.—L. Joussetin.—The author merely describes methods of preparing certain of these salts.

Chemiker Zeitung.
No. 19, May 8, 1879.

Presence of Arsenic in Dark Water Colours.—Dr. H. Fleck.—Attention has been drawn to this subject by the sudden death of a mechanical draftsman. On a *post-mortem* examination the cause of death was first supposed to be an oxalate, and then a narcotic poison. Chemical investigation showed that the liver, kidneys, lungs, heart, and brain were impregnated with arsenic, though the oesophagus contained not a trace, and the stomach with its contents gave a barely perceptible arsenical mirror. The general circumstances of the case excluding the suspicions of suicide and of malicious poisoning, it was found that the deceased had been in the habit when drawing of drawing the pencil filled with colour between his lips in order to point it. The water-colours he had used were analysed, and whilst indian ink, gamboge, carmine, blue (2 which), red eosin ink, and neutral tint were found perfectly free from arsenic, a sample of sepia contained 3.08 per cent of arsenious acid, terra di Sienna 3.14, and a reddish brown colour, the name of which was indistinct, 3.15. Burnt Sienna, Vandyck brown, bistre, bladder green, brown ochre, indian red, umber, raw and burnt, were also found arseniferous. Most of these colours are essentially iron lakes. Hence it appears that the mere presence of ferric oxide, except in a hydrated state and accompanied by free magnesia in quantity sufficient to neutralise the acids of the stomach, does not act as an antidote to arsenious acid. This case seems likewise to prove that arsenic taken in minute doses can accumulate in the system until it can be readily recognised in all organs, and can exert a dangerous action. This result seems to prove that the impunity with which the peasants of Styria consume small doses of arsenic must depend upon circumstances not yet fully understood. (The exclusion of arsenic from such colours, in which it seems to play no essential part, should be insisted on by the authorities.)

A congress of German vine-growers will meet at Coblenz in September next, when the following questions will be discussed:—When and from what is sugar formed in grapes? Under what circumstances does sugar escape fermentation in wine? What recent results have been attained by the use of artificial manures in the cultivation of the vine?

Non-existence of Pentathionic Acid.—According to the *Bull. de l'Acad. Royale de Belgique*, Prof. Spring endeavours to prove that the supposed pentathionic acid is merely tetrathionic acid.

Ineradicable Ink.—The *Apotheker Zeitung* gives the following formula:—1.75 grms. aniline-black are ground up with 60 drops hydrochloric acid and 42 grms. alcohol, and the liquid is diluted with a hot solution of 2.5 grms. gum-arabic in 170 grms. water. If the aniline-black solution is diluted with a solution of 2.5 grms. shellac in 170 grms. spirit instead of gum-water, the result is an ink suitable for writing on wood, brass, or leather.

Preparation of Chemically Pure Tartaric Acid.—Ficius.—The decomposition of the calcium salt with sulphuric acid, or of the lead salt with sulphuretted hydrogen, does not yield a pure product. The author proposes to decompose the zinc salt with sulphuretted

hydrogen. Zinc tartrate is a scarcely soluble salt, easily obtained pure, even from very impure materials. The zinc sulphide obtained as by-product serves for the development of hydrogen sulphide, yielding a solution of zinc chloride, which is used for fresh precipitations of zinc tartrate.

Bulletin de la Société Chimique de Paris,
No. 8, April 20, 1879.

Preparation of Malonic Acid.—E. Grimaux and J. Tcherniak.—The authors first obtain cyanacetic acid and transform this into malonic acid by means of concentrated hydrochloric acid.

Formation of Aurin.—P. de Clermont and J. Frommel.—Phenol is converted into aurin by treatment with a mixture of carbonic oxide and oxygen gases under pressure at 250°. Neither carbonic oxide alone nor carbonic acid produces any effect.

Part Played by Auxiliary Acids in Etherification.—M. Berthelot.—Already noticed.

Certain Catalytic Phenomena due to Viscosity.—Antony Guyard.—The author considers that viscosity, like porosity, is capable of modifying chemical reactions, and possesses a true catalytic power. Glycerin, as a viscous substance, acts in two manners upon the reactions of metallic salts; it modifies the behaviour of these salts with known reagents because it is a non-volatile organic body, and especially because it is a viscous substance. Thus, if glycerin is mixed with a solution of chromic chloride, and ammoniac chloride and ammonia are added, the whole forms an emerald-green liquid, from which chromic oxide cannot be precipitated, just as if tartaric acid had been used instead of glycerin. Analogous reactions are manifested with some other metallic salts when mixed with glycerin and ammonia, or soda. When glycerin and the alkalis have no solvent power upon hydrated metallic oxides, precipitation takes place in the ordinary manner. If a large excess of glycerin is mixed with solutions of a double sulphate of potassa, of titanate acid, sulphate of alumina, ferric chloride, nitrate of lead, or stannous chloride and ammonia is added, all these oxides remain in solution, and are precipitated neither by boiling nor by the addition of water. But if hydrochloric acid is added enough to saturate at once the ammonia and the glycerin, and the acid is again supersaturated with ammonia, the oxides are precipitated as if the glycerin were not present. The addition of an alkaline chloride in sufficient excess to solutions of a metallic oxide in glycerin and caustic alkali determines its precipitation. The author has not succeeded in utilising these reactions in the quantitative separation of metallic oxides.

No. 9, May 5, 1879.

Compounds of Hydrogen Phosphide with Cuprous Chloride, and its Determination in Gaseous Mixtures.—J. Riban.—The reaction of these two bodies gives rise to several compounds, of which the chloride of cuproso-diphosphonium, $\text{Cu}_2\text{Cl}_2\text{PH}_3$, is well defined and crystallisable, though it soon undergoes decomposition on exposure to the air. Hydrogen phosphide when present in gaseous mixtures may be determined by agitation with a hydrochloric solution of cuprous chloride, in which it is rapidly absorbed.

Bromide of Tetraallylammonium and triallylamin.—H. Grosheintz.—The authors obtain this compound by passing a current of ammoniacal gas into an alcoholic solution of allyl-bromide. The mixture liberates heat spontaneously, and a crystalline mass is deposited. Triallylamin is prepared by distilling rapidly crude bromide of tetraallylammonium along with a large excess of recently-fused potassa.

New Organised Ferment of Urea.—P. Miquel.—The author has found in sewage an organism of the Bacilli

class, which, like *Micrococcus ureæ*, possesses the power of resolving urea into carbonate of ammonia, though quite distinct from the *Micrococcus* in its physical aspect. It appears, therefore, that two microscopical species possess approximately the same physiological function.

Precipitation of Lime by Alkaline Carbonates.—E. Drechsel.—The precipitation of calcic carbonate is complete in the cold in the course of fifteen minutes if aided by stirring. It may be effected indifferently either by sodic or ammoniac carbonates in the presence or absence of ammonia or sal-ammoniac. The calcic solution should be introduced into the alkaline carbonate, pouring in a small quantity of the former only at first and stirring for about five minutes before adding more. The solubility of calcic carbonate in alkaline liquids is very trifling.—*Journ. f. Prakt. Chemie.*

Gazzetta Chimica Italiana.
Anno ix., 1879. Fasc. iii.

Characteristic Reactions of Picrotoxin and of Certain of its Derivatives.—A. Ogliarolo.—If a small quantity of pure picrotoxin is dissolved in two drops of nitric acid at 14° and gently heated, there is obtained an amorphous residue of a reddish yellow colour. If two drops of potassa are added a fine bright red is obtained, which, on heating, passes to the colour of old blood. If 2 c.c. of a solution of picric acid at one-half per cent are mixed with potassa at 50 per cent in the cold nothing is observed but a yellow precipitate. On heating to a boil the precipitate dissolves, and the liquid is coloured orange. On cooling there are deposited small prisms of potassic picrate, and the liquid remains of a reddish yellow colour. If the experiment is repeated with the addition of picrotoxin, on boiling the colour of the solution becomes much deeper, and on cooling no crystalline deposit takes place, and the liquid remains intensely coloured. If a little picrotoxin is placed in a capsule and mixed with four or five drops of concentrated sulphuric acid, there appears a golden-yellow colouration which passes into a saffron-yellow; the picrotoxin dissolves, and on adding a little powder of potassic bichromate there is a violet-green colouration, and on dilution with water a clear solution of a yellowish green colour.

Distribution of Cerium, Lanthanum, and Didymium.—Prof. A. Cossa.—Already noticed.

Biedermann's Central-blatt.
Heft 4, April, 1879.

Chemico-agricultural Studies on a (Natural) Irrigation-meadow.—Prof. F. Ullik.—The manurial action of the water seems due to the dissolved substances, while the suspended matters are of little importance.

Ridge Cultivation.—Prof. E. Wollny.—The use of ridges or hillocks is advantageous only in retentive soils or in damp climates.

Nitrogenous Nutrition of Plants.—Prof. E. Heiden.—Cereals require an especial supply of nitrogen and repay it amply; the same may be said of potatoes. With leguminous plants this conclusion does not hold good. Rye and lupins cannot bear ammonia, at least in the form of sulphate, in the earlier stages of their growth.

Nitrogenous Constituents of Pasture-grass and Meadow-hay, and on their Digestion.—Dr. O. Kellner.—Of the total nitrogen present in grass nearly one-third is not in the condition of protein compounds, and can scarcely equal the carbohydrates in nutritive value. In hay the relative proportion of protein has greatly increased.

Can Rubidium Fulfil the Nutritive Function of Potassium in the Vegetable Cell?—Oskar Loew.—The author answers this question in the negative.

A New Oil Seed.—Dr. Eugen Wildt.—The seed in

question is that of *Lallemantia iberica*, cultivated in north-western Persia. It contains a smaller proportion of oil than do rape-seed, linseed, &c., whilst the residual press-cake is richer in nitrogenous matters.

Influence of Various Substances upon Crystallisable Sugar.—MM. H. Pellet and Durin.—A solution of sugar on standing and exposure to heat undergoes less change the stronger it is. Glucose converts cane-sugar into glucose, in proportion to the quantity of the former. In a solution saturated with cane-sugar this change does not take place. At certain temperatures mineral salts have a strong action upon cane-sugar, whilst the effect of organic salts is very small.

Treatment of Phosphatic Minerals.—T. Piltzer.—The phosphates are treated with sulphurous acid under pressure, which is produced by means of the carbonic acid liberated from the accompanying carbonates.

Absorption of Atmospheric Nitrogen by the Leguminosæ.—E. Gatellier has obtained good crops of lucern from an exhausted sandy soil where cereals proved a failure, and concludes that it has the power of fixing the nitrogen of the air. C. Marchand points out that lucern obtains the greater part of its nutriment from the subsoil, and that Gatellier's conclusion is therefore open to question.

Correspondenz-blatt des Vereines Analytischer Chemiker.
Vol. ii., No. 7, April 1, 1879.

Formula of Starch.—R. Sachsse.—Air-dried potato starch contains on an average 17.7 per cent of water. If this is supposed to be chemically combined, as may be inferred from the liberation of heat when it is taken up, starch would almost exactly represent the hydrate $C_{36}H_{62}O_{31} \cdot 12H_2O$.

Examination of Crude Pyrolignite of Lime.—A. Stromeyer.—5 grms. are distilled almost to dryness along with 50 c.c. of a solution of phosphoric acid, of sp. gr. 1.2, and the same volume of water. The operation is repeated with 50 c.c. of phosphoric acid, and again with the 50 c.c. of water. The acetic acid thus obtained is titrated with normal potassa.

Foreign Bitter Principle in Beer.—H. W. Langbeck.—The author prepared two samples of a fermented liquor from solution of glucose with small quantities of tartar, tartaric acid, kino, and a few drops of a mixture of formic and cœnanthic ether. Fermentation was set up by means of sound pressed yeast, and was maintained at a temperature of 18° to 20°. One sample, filtered through flannel after four days and allowed to stand for three weeks in a stoppered cask at 8°, yielded a pleasantly vinous liquid. The second sample, not filtered till after five days, tasted intensely bitter, and grew worse on standing. The newly-formed yeast, at first of a whitish yellow, had taken a brownish colour, died off, was precipitated by the more alcoholic character of the fluid, and formed with the alcohol in nascent state that substance which betrays itself by its bitterness in unhopped fermented liquors when the fermentation has been neglected. The compound in question is by no means innocuous. It was isolated by treating the liquor according to Dragendorff's methods I. and II. The author succeeded in obtaining it in a crystalline form and describes its reactions.

Determination of Solids in Milk.—H. Bering.—The author places about 0.09 grm. of calcined magnesia in a small platinum capsule, determines the tare, and introduces carefully, without touching the sides, an accurately weighed portion of the milk (from 1 to 2 grms.). On evaporation over a small open gas-flame, placed about 40 centimetres below the capsule, the sample is obtained perfectly dry in from two to three hours. That the dried mass is very feebly hygroscopic appears from the fact that 0.214 grm., after standing for twenty-four hours in a half wet room, had not gained 0.004.

Hannoversche Monatsschrift wider die Nahrungsfälscher.
Vol. ii., No. 2, February, 1879.

Sewerage, with Especial Reference to the Liernur System.—Dr. F. Fischer.—The author shows that in any town where the Liernur system was fully introduced, five-sixths of the urine would still find its way into the sewers. Even where cess-pools are lined with masonry, according to the observations made by Pettenkofer at Munich, nine-tenths of the excrementitious matters find their way into the subsoil. The cost of the Liernur system, including interest and sinking-fund for paying off initial outlay, is from 15s. to £1 yearly per head, and a system of sewers is still required.

Physical Properties of Fats.—The author does not consider that specific gravity affords a trustworthy means of deciding whether a sample of butter is genuine or sophisticated. Examination by polarised light supplies a much better characteristic. Mylius, who first called attention to this method, considers it of only limited applicability. The author is of a different opinion, as it is very rare for a butter to be sent for analysis after it has been melted. Pure butter, when examined with a magnifying power of 200 to 300 diameters, appears as a conglomerate of round and roundish drops of different sizes, interspersed here and there with characteristic salt-crystals. All melted fats after congealing take a crystalline structure. On examining a facitious butter we find not the above-mentioned globular drops, but more or less perfectly developed crystals, readily detected by the experienced eye, especially with an oblique illumination. All doubt is at once removed on examination by polarised light. The crystals come out very distinctly, and if the upper Nicol is slowly turned everything non-crystalline becomes gradually darker, whilst everything of a crystalline nature becomes lighter. The author finds, further, that different fats, like different minerals, produce characteristic differences in the polarisation colours. He announces the early publication of a series of plates showing the characteristic forms and colours of each fat, whether raw, melted, or crystallised from glycerin. Mutton tallow always gives a blue tone, and the contrasts when the Nicols are exactly crossed are sharper than in case of any other fat, except, perhaps, cacao-butter. The latter differs most characteristically from all other fats, and the play of colour from the deepest red to the brightest green does not admit of description. The fat of oxen displays merely green and white luminous effects. Small semilunar and vermicular bodies of a bright green appear by common light. Hog's lard displays many colours, especially red and blue, yellow, which is very conspicuous in cacao-butter, being wanting. These optical reactions are available for the detection of foreign fats fraudulently added to chocolate or cocoa.

MEETINGS FOR THE WEEK.

TUESDAY, 17th.—Zoological, 8.

WEDNESDAY, 18th.—Meteorological, 7.

THURSDAY, 19th.—Royal, 8.30.

— Philosophical Club, 6.30.

— Zoological, 8.

Chemical, 8. "On Gardenin," Dr. Stenhouse and Mr. Groves. "On the Action of Sulphuric Acid on the Hydrocarbons of the Formula $C_{10}H_{18}$," Drs. Armstrong and Tilden. "Researches on the Terpenes, Camphor, and Allied Compounds (Parts I. and II.)," Dr. Armstrong. "Contributions to the History of Starch and its Transformations," H. T. Brown. "On the Boiling-points of Certain Metals and Metallic Salts," Dr. Carnelly and W. C. Williams. "On the Determination of Nitric Acid by means of Indigo," R. Warington. "On Dry Copper-zinc Couples and Analogous Agents," Dr. Gladstone and Mr. Tribe. "Notes on the Purple of the Ancients," R. Schunck. Ballot.

ERRATUM.—P. 249, col. 2, line 6, for "invite" read "unite."

A German Chemist (Ph.D.), holding diplomas from University and Polytechnicum, who has already had experience in a manufactory, seeks a Situation in a Chemical Manufactory in England.—Address, K.D., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Required by an Associate of the Royal School of Mines, F.O.S., &c., a Situation in a Laboratory, or as Manager of a Chemical or Metallurgical Works, or on a Mine, in England or abroad. Highest references.—Address, A.R.S.M., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Wanted, by a Young Man (29), a Situation either in Works or Town Laboratory. Ten years' experience and accustomed to management of men. Has had considerable practice in water, manure, and sugar analyses; also in original investigations. Good references.—Address, F.C.S., Tron-deg, Abergale.

TO ANALYTICAL AND MANUFACTURING CHEMISTS.

Wanted a Junior Assistantship, by a Gentle-man aged 19 years, with 2½ years' laboratory experience. Is well up in water analysis for sanitary purposes, and is very steady and devoted to his profession. Reference permitted to Professor Atfield.—Address, E.R., Oxford Villa, Montague Road, Uxbridge, Middlesex.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woollen Shoddy; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and Co., Clayton, near Manchester.

Superior Iron Filter-Press for Sale, made to order and of extra quality, by Messrs. Needham and Kite. It contains ten chambers, each 19×21½ inches; is provided with a 3-inch gun-metal pump to work by hand or steam, and with fittings for washing and steaming, which can be used or not at discretion. The whole is quite equal to new, and is in perfect working order.—Address L.B.S., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London E.C.

DAVID HILL, CONSULTING CHEMIST in Technical Processes, late of Dean's Terrace, South Shields. Letters to be addressed care of Messrs. R. Bullock and Co., 79, Mark Lane, London, E.C. Special attention given to questions relating to "Noxious Vapours."

CHEMICAL AND COLOUR WORKS,
FROGMORE, WANDSWORTH.

MR. J. STONEHEWER has been favoured with Instructions to SELL BY AUCTION, on the Premises, as above, on THURSDAY, JUNE 19, 1879, at Twelve for One o'clock, in Lots, the remaining valuable Plant and Machinery, and other Effects, of the above extensive Manufactory (the Site having been disposed of), comprising numerous large Wrought-Iron, Zinc, and Wooden Tanks and Vats, Air-Pump and Engine, a Centrifugal Pump (by Patterson), Pressure Boilers, Evaporating Pans, a capital Filter-Press, Weighing Machines, and other Plant and Machinery; about 500 lbs. of Magenta and other colours; also the contents of the Laboratory; Iron Piping, Steam and Gas Fittings, Weston's Blocks, Pulleys, and Chains, Portable Pumps, Furnace Doors, &c.; Stone, Slate Slabs, and miscellaneous items.—On view the day prior and morning of Sale, and Catalogues to be had on the Premises and of the Auctioneer, 3, West Hill, High Street, Wandsworth.

MINERALOGY AND GEOLOGY.

NEW LIST of Collections of Minerals, Fossils, and Rocks, with prices. New List of Minerals for Chemical Purposes, Manufactures, and Research. New List of Varieties of Rocks. New List of Prices and Sizes of Cabinets for Natural History and other purposes. New Catalogue of Secondhand and New Books on Geology and Kindred Sciences. New Supplementary List of Books. New List of Sections of Rocks and Minerals for the Microscope. New List of Prices and Patterns for Geological Hammers. New List of Blowpipe Cabinets, Apparatus, and Materials. Also Implements and Appliances for practical work in Geology and Mineralogy.

Post free on application to JAMES R. GREGORY, Geologists and Mineralogists' Repository, 88, Charlotte Street, Fitzroy Square London.

IMPORTANT TO SULPHURIC ACID MANUFACTURERS.
NORRINGTON'S PATENT.

In the ordinary method of Manufacture, at the time of charging the Kilns, a considerable escape of gases takes place. This is attended with proportionate loss of Sulphur, and with much inconvenience to the workmen, as well as annoyance to the vicinity of the Works. This may be entirely avoided by the adoption of C. Norrington's patented invention, which can be applied at moderate cost to existing Plant, as well as in the erection of new Works. It may be seen in full operation on extensive Plant at Messrs. C. Norrington and Co.'s Chemical and Manure Works, Cattedown, Plymouth, where the fullest information may be obtained, with terms for license.

SPECIALITIES.
MANGANESE Lump, Crystallised, Ground, and Prepared Large stock of every description.
*** Suitable for all Trades.*
ARSENIC Refined powdered, Lump Grey, and Ruby.
FLUOR-SPAR Finest produced. Medium and Common for all purposes.
BARYTES Carbonate and Sulphate. All qualities of Lump and Ground.
BAUXITE Of high percentage of Alumina and low in Iron;
 CRYOLITE, MAGNESITE, CHROME ORES, EMERY STONE, AND ALL MINERAL ORES &c.

GEO. G. BLACKWELL,
 MINERAL AND CHEMICAL BROKER,
 5, CHAPEL STREET, LIVERPOOL
 NOTE.—SPECIAL ATTENTION is directed to my CARBON-ATE AND SULPHATE OF BARYTES as the *finest* produced, being clean, crystallised, free from Lime, and of the *highest test*.

TETRACHLORIDE OF CARBON.
BISULPHIDE OF CARBON.
CHLORIDE OF SULPHUR.

JESSE FISHER & SON,
 Phoenix Chemical Works Ironbridge.

S. A. SADLER,
 CLEVELAND CHEMICAL WORKS,
 MIDDLESBROUGH;
 Newfall Tar Works, Carlton;
 Ammonia Works, Stockton-on-Tees;
 and Stamshaw Chemical Works, Portsmouth.
And also of the Furness Tar Products Co., Ulverston.

Manufacturer of Benzole, Toluole, Xylol,
 Solvent and Burning Naphthas, Carbolic Acid and Disinfecting Powder, Refined Anthracene, Naphthaline, Black Varnish, Refined Tar, Crude Liquid Ammonia, Coal-Tar, Pitch, Creosote, Grease, Sulphate of Ammonia, Pyroligneous Acid, Acetate of Lime, Wood Naphtha, Charcoal, &c., &c.
 S. A. S. is always a buyer of Coal-Tar Naphthas, Crude Anthracene and all Tar Products.
All communications to be addressed to the offices at Middlesbrough.

EARP & CHASTER,
RUNCORN,
 MAKERS OF
CHEMICALLY PURE MINERAL ACIDS,
LIQUOR AMMONIA, &c.

PATENTS.—Mr. Vaughan, F.C.S., British, Foreign, and Colonial PATENT AGENT. Special attention given to inventions relating to Chemistry, Mining, and Metallurgy "Guide to Inventors" Free by Post.—Offices, 67, Chancery Lane London, W.C., and 8, Houndgate Darlington.

DARTON'S GIMEN POCKET DIRECT-VISION SPECTROSCOPE IN CASE COMPLETE, 21/-.

DARTON'S CHEMICAL SPECTROSCOPE in POLISHED CASE 63s.

Retort Stands, Bunsen's Burners, Gas Furnaces, and Chemical Apparatus of all kinds Made and Repaired for the Trade.

F. DARTON & CO.,
 45, ST. JOHN STREET, WEST SMITHFIELD, E.C.

(ESTABLISHED 1834),
*Makers to the Science and Art Department,
 South Kensington.*

Vol. XXXIX. No. 1021.

DETECTION OF FIRE-DAMP.

By Dr. R. ANGUS SMITH, F.R.S., &c.

THE detection of fire-damp, marsh-gas, or mine-gas, has occupied many minds since the time that Sir Humphry Davy began his enquiries and invented his celebrated precautions. I have often thought of two methods of testing for the gas, but only lately had them really tried. The first is by the use of the small instrument called, unfortunately, a compression syringe. It is commonly used for very rapidly compressing a small tubeful of air, so as to cause it to heat and ignite a piece of tinder. The tube used to be made of glass, but lately a method, inferior as I think, since the action becomes hidden, is employed, and the compression is made in a brass tube. A piston, which fits well, is put into the tube, and driven down rapidly by a blow with the palm of the hand on a smoothly rounded piece of wood at the top. As it was important to see the effect directly, a glass tube was necessary, and various substances were subjected to the heated air, so as to obtain a little experience as a beginning. There was no good tinder at hand, and cotton-wool in small quantities failed to ignite until it was well dried. Charcoal-dust ignited readily without special preparation. Minute quantities of gun-cotton at first did not take fire, and made the experimenters too bold, which ended in the shattering of the tube, which was 7 m.m. thick, and 6 m.m. internal diameter. When there was uncertainty the trial was made in the dark, and it was found that when a good lubricant was obtained there never was a failure; a spark was elicited readily. Coal-dust gave many sparks; ether fired readily, and a mixture of coal-gas and air exploded, bursting also more than one tube. It happened, however, that in trying the lubricant to see if the piston went down with ease, common air only being used, there was still a spark, and at last when the apparatus was in good order one was obtained on every occasion. It seemed clear that the olive oil used for lubrication was itself ignited. There were flashed alcohol, ether, turpentine, charcoal powder, coal powder, cotton-wool, olive oil, Young's lubricating oil.

The work, which had been at first difficult, had become at last too easy. The next step was to seek a non-combustible lubricant, and for a time a thick emulsion of oil and soft soap was used. This did not give any sparks alone, but the use of water is an objection. A strong glass tube, such as is sometimes sold for the compression, was shattered by one of the gas mixtures. For small explosions thinner tubes were used, $\frac{1}{4}$ m.m. in thickness of glass. Eventually this glass tube was put within a brass one 0.5 m.m. thick, in which was a window to allow the spark to be seen. Even this glass tube was shattered, giving way at the window, and bulging out the brass when 20 per cent of marsh-gas was added and exploded. I decided to have a much stronger tube, and that now made is unnecessarily thick. The glass is used only for about two inches at the bottom, and as the diameter must be at least as great as that of the brass it is necessary to put it in from below. To effect this a cap is made to screw upon the larger tube; this cap contains the glass tube, part of which forms the glass of the window. The screw is $\frac{1}{2}$ in. long, so as to hold well. The glass must not be closed below by the blowpipe, as a blow upon the conical base, or even a base of any shape, readily breaks it, and the piston may at times go quite to the bottom. The airtightness must therefore be produced by a good stuffing between the glass and the brass as well as

on the screw. The glass is covered with an india-rubber tube, and the two are put into the brass tube, previously having the bottom and sides well covered with glue, the best substance for this yet found. A mixture of resin and wax (and even caoutchouc if dry) was itself ignited by the improved mode to be mentioned.

This very strong apparatus has not yet been much tried, but before it was got a series of trials was made, by which it seemed certain that less than 5 per cent of marsh-gas could not be distinguished in air. In order to increase the delicacy of the process there was inserted a small amount of platinum-black, a very small amount is enough. The use of platinum I have had in view for several experiments in condensation of gases, and here it was found remarkably successful, bringing down the amount of marsh-gas to be detected to $2\frac{1}{2}$ per cent. On the other hand, it was necessary to use a lubricator without oil, so that the friction is considerably increased; at present we are using soap only.

The amount of gas detected is not minute, but it is a quantity which will not explode, or flash, or spark, unless under such exceptional circumstances as are here mentioned. It would be quite safe to make this explosion in any atmosphere, as the flash is confined to the tube, and a man could go in the dark and, as it were, feel the state of the air by making a spark as he went along. The apparatus needs nothing to be renewed except the air within. The piston must be taken out and care taken to bring in a fresh supply of air to be tried. The mode of doing this must have some attention. It must not be done by blowing as some might suppose, but it might be done by putting a fine tube into the cylinder and sucking out the air that had been compressed, and so letting fresh air in. It might also be done by having a stopcock below and letting the air in by that method, but the difficulty of keeping the joints tight is remarkable. The use of a loose plunger of wood to drive out the air is probably the easiest. The blow has a wonderful power. The cylinder and piston are only 8 m.m. in internal diameter, and the compression is more than thirty atmospheres, about 420 lbs. on the square inch.

Another method has gained my attention. Some time ago Mr. Ansell proposed to find the influx of fire-damp into the air of mines by using its diffusive power. By a well-known law of the diffusion of gases, the marsh-gas or fire-damp will pass into a porous vessel, if filled with common air; and if the covering is of caoutchouc the pressure will raise it. The rise of the cover may be used for making a communication with an electric bell, and this is the method Mr. Ansell used.*

The action is very rapid, but the raised caoutchouc soon falls. Besides this the air inside requires to be heavier than the outside gases which are expected to enter. It would be necessary to keep a supply of this air in order to make the apparatus self-acting, as it was intended. I did not obviate this difficulty, but designed simply the mode of filling the vessel with nitrogen, a gas nearly of the same specific gravity as air. When the experiment was to be made the vessel was filled with the nitrogen, and passed into the air to be tried. The pressure at once began within from the entrance of the lighter gas, and it raised a needle which was made to magnify the movement considerably.

This apparatus required, first, a solution of chloride of ammonium, next, chloride of lime. These mixed gave the nitrogen, which was made to pass into the vessel with the expandible cover. The pointers required some steady place on which to point, and the whole required a box. The plan was not found convenient, and it did not indicate under 5 per cent of marsh-gas as it was tried, but by varying the apparatus it could certainly be made to indicate much less. Such an apparatus may in some cases be found useful, and I give an account of it for that

* A full description of the apparatus alluded to will be found in the CHEMICAL NEWS, vol. xii., p. 280, by Mr. George Frederick Ansell.

reason. The first-mentioned is certainly the handiest when people require to move about, and the experiment can be done in the dark; whereas this second plan needs a steady place and light. Still, it is sound in principle, and may be a useful supplement to Mr. Ansell's apparatus, which the late Lord Kinnaird, a lover of everything that promised good to the working classes, was very desirous of introducing as a common instrument in coal-mines.

READY METHOD FOR PREPARING DIPHENYL.

By WATSON SMITH, F.C.S., F.I.C.

By the adoption of the following method I have found that a rich yield may be obtained of the above hydrocarbon, and the experiment is easily carried out, proceeds rapidly, and without any danger. 62.4 grms. of benzene are mixed in a flask with 52 grms. of tin tetrachloride, or at least this proportion is observed, and the mixture is poured little by little into a dropping-tube, which allows it to fall drop by drop into a tube of Bohemian glass, itself lying in a combustion-furnace, and maintained at a bright red heat. The combustion-tube should be bent at the outlet, almost at right angles, so as to pass through a cork fitting into a wide-necked bottle. A tube passes from this bottle to another large bottle containing some water and also a quantity of blotting- or filter-paper. This arrangement serves to partially condense the hydrochloric acid evolved,

but another tube passes from this bottle into a draught-place, or through a window, to lead off the uncondensed gas. There is no need to pass the evolved gases through a Liebig's condenser, for if a bright red heat be maintained not more than one drop of undecomposed benzene would be condensed, the above weights being taken. The diphenyl is found mixed with stannous chloride in the receiver in solid masses. Separation is easily effected by warm concentrated hydrochloric acid, which dissolves the stannous chloride, and leaves behind diphenyl. The latter is purified by distillation alone, and finally with steam.

In a paper read before the Chemical Society, and published in the *Journal* (July, 1876, and November, 1877), I recommended distilling the contents of two flasks into the red-hot tube, one containing the tin tetrachloride, the other the benzene, and so that the vapours of the benzene passed through the flask containing the tin tetrachloride heated up to boiling. I now find that the method above recommended is much safer and easier of execution.

Widmannstätten's Figures on Artificial Iron.—J. Lawrence Smith.—These figures, developed by the action of an acid upon a polished surface, have been considered characteristic of meteoric irons, some of which, however, do not show these figures. The author has succeeded in producing them upon silicide of iron. *Comptes Rendus*.

ON NITRIC NITROGEN IN GUANO.*

By ROBERT R. TATLOCK, F.R.S.E., F.C.S.

PART I.

FROM the results of some experiments which I made many years ago, I was led to the conclusion that a large proportion—in some cases nearly the whole—of the nitrogen existing as nitrates in guano appears, and is estimated as ammonia, in the ordinary process of combustion with soda-lime. As there are no means known, so far as I am aware, even up to the present time, of preventing the conversion, in presence of organic matter, of a very indefinite but always large proportion of the nitric nitrogen into ammonia, it follows that all determinations of the latter made in guano are inaccurate unless they are based upon the complete decomposition of the nitrates with production of ammonia from the whole of their nitrogen; and I am not aware that up till now this has been accomplished, or even the necessity for it admitted. The amount of error will depend chiefly on the ratio of the nitrates to the organic matter present, but will also be much influenced by the nature of the latter as well as by the completeness or otherwise of its admixture with the subject of the analysis. As it is not uncommon for natural guanos to contain from 1 to 2 per cent of nitrates, the error due to partial or imperfect decomposition of the latter is considerable, but in the case of guanos or artificial manures which have been purposely mixed with a considerable proportion of a nitrate, such as nitrate of

soda, it is much augmented, and if, say 10 per cent of the last named substance has been employed, the error may and probably will be as great as 1 per cent of ammonia—to the low side if it be assumed that the whole of the nitric nitrogen is obtained as ammonia, and to the high side if it be assumed that none of is obtained, in that form—in which case it is of course determined by a separate process and added to the result obtained by the ordinary combustion with soda-lime. I was surprised to learn, recently, that the latter was the practice of chemists who had had a very large and varied experience in agricultural analyses, and the effect of it is that purchasers of guanos and manures containing nitrates either naturally, or artificially introduced, on the basis of their analyses, must pay for a large proportion, and in many instances practically the whole of the nitric nitrogen twice over. It is possible that this practice, erroneous as it is, has arisen from the circumstance that when nitrates are heated to redness with soda-lime, no ammonia is obtained; at any rate I have ascertained this by direct experiment. The result is very different, however, when organic matter is present, ammonia being always produced, varying in amount according to the nature and proportion of the organic substance and other circumstances. Being desirous of obtaining some reliable method by which the whole of the nitrates could be converted into ammonia during the

combustion, and as it seemed hopeless to expect to find any means of preventing the production of ammonia, to a large extent, from them, in presence of organic matters such as are invariably present in guano, I undertook the following series of experiments with the object of determining the effect of organic matters of different kinds and in different proportions in the production of ammonia from alkaline nitrate, in the ordinary combustion process by soda-lime.

In the trials made with starch the necessary correction was made for the organic nitrogen naturally present (which was found to be 0.10 per cent) before the results were recorded in the table.

The combustions were made in the ordinary way, 40 grammes of soda-lime being employed in each case, the ammonia collected in dilute hydrochloric acid contained in nitrogen bulbs, as usual, and weighed as chloro-platinate of ammonium. The organic matter was intimately ground with the nitrates; this mixture was then first ground with a portion of the soda-lime, and the result well mixed with the remainder. (See above.)

It will be seen from this table that the following conclusions are deducible from these experiments:—

1. That using 3 of organic matter (starch) to 1 of nitrate, 45.30 per cent of the nitric nitrogen can be obtained.
2. That in no case was the whole of the nitric nitrogen converted into ammonia, the greatest proportion being 97.40 per cent.
3. That the results are somewhat variable even with the same proportion of the ingredients, something always depending on the completeness with which the mixture is made.

It will readily be conceded that in guanos where the proportion of organic matter to nitrates is very high, as is the case in ammoniacal guanos, it is quite erroneous to determine nitric nitrogen by a separate process and add it to the nitrogen obtained by combustion with soda-lime, it being already included therein. It follows from this consideration and from these experiments that it is best to conduct the combustion in such a way as to convert as much as possible of the nitric nitrogen into ammonia, and that if it is determined separately in order to distinguish it from that existing in other forms, it should not in these circumstances be added to the nitrogen, in which it is already included.

The following detailed analysis which I have made of a sample of "Huanillos" guano will serve to show, by observing the ratio of the organic matter to the nitrate, that at least one-half, probably much more, of the nitrogen contained in the nitrate will be estimated in the process of combustion:—

With regard to the best methods for the determination of the nitric nitrogen in guanos there is still a great difference of opinion. Methods based upon the liberation of nitric acid, and the determination, directly, of the oxidising power of the liberated acid, are erroneous and misleading, from the fact of the well-known action of nitric acid, especially when largely mixed with strong sulphuric acid upon soluble organic matters such as are always present in ammoniacal guanos. The indigo method of Boussingault is an example of these, although it is recommended by experts in agricultural analyses; and that of Harcourt, by distilling with zinc, iron, and caustic alkali, although a minutely accurate one for estimating nitrogen, when properly applied, as I can testify from a long experience of it, is not applicable to guano on account of the soluble nitrogenous matters always present, and which even permanganate of potassium only partially destroys. Yet this method is recommended by skilled analysts, with the sole precaution of removing the ammoniacal salts before applying it,

although the inevitable result of its use is that the organic nitrogen is included with the nitric nitrogen. The consequence of employing this method in conjunction with the practice of adding the nitric nitrogen to that obtained in the combustion process is that part of the nitrogen is stated, and consequently paid for three times, the organic nitrogen being inadvertently determined with the nitric nitrogen, and both added to the nitrogen obtained by combustion, which already contains both.

Pelouze's method, based upon the oxidation of ferrous salts by the liberated nitric acid, in an atmosphere of carbonic acid, I have found to give good results in some cases; but they are no doubt too low where much soluble organic matter is present, even if the latter be removed as far as possible by permanganate of potassium.

Crum's process (*Proceedings of the Philosophical Society of Glasgow*, 1848, p. 162), besides being a really scientific one, and capable of great accuracy, is free from the objection of giving too low results in presence of soluble organic matter; for although the latter is acted upon by the nitric acid, it is a matter of indifference what reduces the latter if only nitric oxide be produced, by the measurement of which the nitric nitrogen is estimated. It seems necessary, however, to prove, where organic matter is present, that the evolved gas consists entirely of nitric oxide, as a little nitrogen sometimes appears, probably as a result of the action of the strong sulphuric acid on nitrogenous organic matter. This can easily be done, as Crum describes, by introducing into the nitrometer some warm solution of iron sulphate, observing the amount of gas absorbed and regarding this only as nitric oxide.

I am at present endeavouring to obtain the perfect resolution of the nitric nitrogen into ammonia, and am also conducting some experiments with the view of finding the method best adapted for estimating nitric nitrogen in guanos and manures.

ON THE DIFFERENT ANILINE-BLACKS.*

By JUSTUS WOLFF.

IN the first instance there are two different series of aniline-blacks, viz., those which are produced in or on the fibre, and those which are manufactured first and then applied to the fibre by the usual dyeing process.

The first-named series were invented by the late Mr. John Lightfoot, of Accrington, in the year 1866, and are extremely well adapted for printing black on vegetable tissues, being in some cases the best black-print out.

Many various fruitless and expensive efforts have been made to dye fibres and fabrics by the Lightfoot process and its improvements, but have failed, although the shades of the black produced by some of the methods in these series are extremely beautiful.

The greatest difficulty in dyeing according to Lightfoot's process is to get the shades evenly distributed over the fibres and fabrics, and it has not yet been overcome satisfactorily, although many experiments on a very large scale have been made for that purpose in Bradford and Manchester dye-works with cotton goods.

The difficulties in dyeing worsted and silk tissues by these and kindred processes in even shades are still greater, and that is the reason why this beautiful and fast dye is not produced on yarns and fabrics on a large scale except by printing on cotton, in which application it far surpasses all other black print by beauty of shade.

The methods of dyeing yarns and woven fabrics according to the Lightfoot process consist principally in soaking them thoroughly and evenly in a strong solution of aniline hydrochloride, with or without free aniline, and potassium chlorate, with or without the addition of other—especially metallic—compounds, afterwards exposing the goods

in a moderately warm place to the action of air for such a length of time until all is of a dark green colour, and subsequently passing them through a warm bath of soda, which develops the black in a short time. Instead of the soda-bath, a bath with small quantities of chrome and hydrochloric acid develops a much deeper and finer black, which does not turn green.

Of course there are nearly as many modifications of this method of dyeing as there are dyers, colourists, and chemists, who have been trying it, and have modified the original process with a view to improve upon it, many of them succeeding to a certain extent, but none completely.

The introduction of vanadium in these processes (which is not new, as the late Mr. John Lightfoot mentioned it in his Patent specifications) was certainly a great improvement, but even with its aid it was impossible to overcome the difficulties in dyeing mentioned above. Even supposing these difficulties had been overcome, the process of dyeing Lightfoot-black would be a very tedious one on account of the length of time needed for the development of the green colouration and the great number of baths the goods would have to pass.

The Lightfoot-blacks can be divided into those which turn green by exposure to air, and those which remain black under the same circumstances. The first are common and the second the oxidised Lightfoot-black. The shades of these series of blacks run from blue, dark bluish-grey, blue-black, grey, and black to brown-grey brown-black, and even to brown and black-brown.

The first link of these series is the blue which the Dr. Crace-Calvert invented and obtained by the action of aniline hydrochloride with a smaller quantity of potassium chlorate than for black, and some ferrous sulphate in order to moderate the oxidation. Next to this blue ranges Lightfoot's blue-black, and then follow the other shades in the succession given above.

These blacks, in common with the other aniline-blacks, are mixtures of at least two shades, viz., of a very deep blue and deep brown, the latter varying from reddish brown to yellowish brown, which quality enables it to produce many different shades of black in combination with the deep blue.

The purer the aniline—that is, the less toluydin it contains—the bluer is the black produced by that process, thus showing that the brown colouring matter accompanying the blue in the Lightfoot-blacks owes its origin to toluydin contained in the commercial anilines, even if only in small quantities.

Some metallic compounds—as, for example, of copper, cerium, vanadium, and certain others—have the property to deepen this dark blue to a very fine blue-black, even if employed only in small quantities, by their ability to increase the strength or power of oxidation.

The stronger the action of oxidation, up to a certain degree, on the aniline or the aniline salt the darker becomes the product of that oxidation, whilst the weaker the action of oxidation the bluer the shade obtained. On this principle a blue or black can be produced from the same quality of aniline.

As to the chemical constitution of the Lightfoot-blacks not much is known, and the investigations made to that purpose have not yet thrown much light on that dark object.

According to Reinbeck's results of research, the Lightfoot-black is a powerful base of violet-black colour, forming with acids green coloured compounds.

A. Müller's formula of Lightfoot-black, as the result of direct elementary analysis, $C_{12}H_{14}N_2O_{11}$, is an improbable one on account of the large proportions of hydrogen and oxygen. Without regarding this last-named defect, the proportion of carbon and nitrogen would allow us to consider it as a derivative from diphenylen-diamin by powerful oxidation.

A more reliable elementary analysis published by Goppelsröder (*Dingler's Polytechnisches Journal*, ccxv., 439 to 448) leads to the empyric formula $C_{24}H_{26}N_4$ for the

* All temperatures are given in Centigrades.

common Lightfoot-black; he interprets in it the following ways.—

of which he considers the first as the most probable one. The chemical constitution of the oxidised black is, then,—

Whilst the reduced common black he represents—

With potassium bisulphate he produces naphthalin-pink from the Lightfoot-black:—

wherein the following decomposition of potassium bisulphate takes place:—

Another author produces by treatment of Lightfoot's black with aniline a fine aniline-pink of the formula—
 $\text{C}_{36}\text{H}_{33}\text{N}_5$.

These investigations have been made on the aniline-black produced by electrolysis, which is identical with the Lightfoot-black. All these formulæ of aniline-blacks show that they are the products of a powerful oxidation simultaneously with a considerable condensation.

It is very probable that in Lightfoot-black a connection of nuclei has taken place (an interpretation supported by the production of naphthalin-pink with bisulphate of potassium, as stated by Goppelsröder, by the property to form products of substitution with aniline,—aniline-pink—and also by some analogies coming forth in the course of this paper), which leads to the following formulæ for Lightfoot's black:—

The oxidised black—

The reduced Lightfoot-black—

Or—

Turning now to the other aniline-blacks, viz., those which are manufactured from aniline first, and then when ready are applied to the fibres by the usual dyeing process, we meet with two series, which we will keep distinct by the names used for them in commerce, viz., indulin and nigrosin.

The name nigrosin I gave to that series of black which I invented in the year 1862, in the laboratory of Messrs. Appold Frères, in Sulzbach, near Saarbrücken. But since then this name has been usurped by some firms for colouring matters belonging to the indulin series in order to sell an inferior article at the price of the real nigrosin.

The first link of the indulin series I found out in 1865 by treating the bases of magenta-refuse with aniline and acetic acid, a process very similar to that of the production of aniline-blue from magenta. The spirit-soluble indulin produced by that process was converted with oil of vitriol into the water-soluble indulin, fraudulently called by some firms nigrosin.

The indulins are manufactured in several ways; first from magenta refuse:—

The refuse is treated with boiling water containing hydrochloric acid in order to extract the salts of mauvanilin, rosanilin, and chrysianilin completely, and to leave the violanilin salt undissolved, which is decomposed with caustic soda, and by this treatment the violanilin base is obtained in a free state. To convert this violanilin (or also mixtures of bases containing it in the largest proportion), a mixture of say, 10 parts dry violanilin, 6 parts commercial acetic acid (of the equivalent 120), and 20 parts aniline for blue, is heated to between 140° to 160° as long as ammonia is developed, and till the mass dissolves in alcohol (acidulated with acetic acid) in the desired shade. Arrived at that state, the excess of aniline is liberated by addition of caustic soda sufficient to neutralise the 6 parts of acetic acid (which are in the mixture), and driven off by a current of steam. The indulin base thus obtained is separated from the solution containing acetate of soda, washed, powdered, and dried, and may be used in that state directly for conversion into the water-soluble state; but it may also be purified by treating it several times with boiling acidulated water in order to obtain the salts of the indulin bases, which also have to be dried before conversion. This conversion is effected in the following manner:—

Into three or four parts of oil of vitriol of 66° B., or, if needed, of fuming oil of vitriol (Nordhausen vitriol oil), or mixtures of both, heated up to about 100°, one part of dry indulin base or its salts is given in slowly whilst the liquid is well agitated. When all is in, the heat is raised to about 120° to 140°, and kept there for such a length of time (about five hours) till a sample drawn and completely washed with water (in order to remove all free sulphuric acid), and treated with ammonia at about 60° or 70°, dissolves quickly and completely. This point reached, the solution of the colour in oil of vitriol is, whilst yet hot, poured into about five times its weight of clear cold water, which is well agitated, then settled for several hours, the water drawn off, and the sediment repeatedly washed in this way with fresh quantities of water till it produces no perceivable sour taste. Then it is filtered and boiled with caustic soda solution, just sufficient to dissolve it and to form a neutral salt, and then dried down at a temperature not higher than 70°. Sometimes in place of soda ammonia is used. It forms then the water-soluble indulin.

Another way to produce indulin is by heating a mixture of 10 parts aniline (possibly pure preferred) with 20 parts of syrupy arsenic acid (containing 70 per cent of dry

acid) to 185° to 190° for such a length of time, till it forms after cooling a dull yellowish, bronze-coloured, brittle substance.

At that state most of the aniline is converted into violanilin, which is obtained pure by neutralisation of the arsenious and arsenic acid in the melt with caustic soda, driving off the un-converted aniline by a current of steam, separation of the melted violanilin base from the water (formed by condensation of steam), powdering, and drying it. This base is converted with aniline and acetic acid into the spirit-soluble indulin or its base (as described above), which is made soluble with oil of vitriol, similarly as the indulin base from magenta refuse.

Violanilin is also produced by the action of arsenic acid on aniline hydrochloride, or other suitable salts of pure aniline; further, by the action of pure nitro-benzene on pure aniline alone, or mixed with aniline salt, and in general by the action of suitable oxidising or dehydrogenating substances on pure aniline or suitable aniline salts at a temperature of 185° to 190°. Also, for example, by a current of chlorine gas into aniline at 180° to 190°, and then, on the same principle, with a mixture of nitrate of aniline with aniline salt, or by a mixture of nitrate of soda with aniline salt in excess, and so on.

Of course in all these processes some other substances besides violanilin are coming forth, but the latter will be the principal one if the operation is conducted very carefully, and the temperature of forming violanilin does not rise higher than 190°. Above that temperature other decompositions take place, and by-products will be formed to a great extent—as, for example, triphenylen-diamin-blue, &c.—but which to take into consideration would complicate this paper to an enormous extent. Therefore I will only treat on the principal substances formed in the largest proportions by these processes, under the supposition that they are carefully conducted.

As an explanation of the chemical reactions going on in the processes above described I give the following:—

Violanilin is the product of elimination of hydrogen from pure aniline, and simultaneous condensation.

Mauvanilin is the product of elimination of hydrogen and simultaneous condensation of a mixture of two molecules of aniline and one molecule of toluidin.

Both these reactions are represented in the following:—

3 aniline - 6 hydrogen = violanilin.

2 aniline + 1 toluidin - 6 hydrogen = mauvanilin.

The reaction of nitro-benzene on aniline, or aniline hydrochloride, or mixtures of both, is as represented by the following formulæ:—

2 aniline + 1 nitro-benzene = 1 violanilin + 2 water.

And that of nitro-benzene on a mixture of aniline and toluidin—

If there is no hydrochloride of aniline, or of that of aniline and toluidin, and no free aniline or toluidin to be acted upon, then the process must be watched carefully, and by all means be kept below 190°, else a quantity of by-products is formed, much easier than the same process without hydrochloric acid. A sudden reaction (especially on a large scale) takes place, producing a rise of temperature by itself at once, and forming a large quantity of by-products. Therefore, if the temperature should rise above 190° the mixture should be cooled down by the addition of water whilst agitated, and by these means the temperature should be kept within the limits given above.

The conversion of violanilin with or without mauvanilin into spirit-soluble indulin is caused by the substitution of one, two, or three hydrogen atoms in the appendants by phenyl.

If acetate of violanilin with or without mauvanilin is heated with aniline for blue to 140° to 160°, then indulin is formed, and the above-named substitution takes place, producing in the first instance the mono-phenyl-violanilin.

In the second stage of the process diphenyl-violanilin is formed—

2 aniline + violanilin = diphenyl-violanilin + 2 ammonia.

If that process is carried on so far till the formation of ammonia ceases, then a complete substitution of the hydrogens in the appendants has taken place, and triphenyl-violanilin has been formed.

acid) to 185° to 190° for such a length of time, till it forms after cooling a dull yellowish, bronze-coloured, brittle substance.

At that state most of the aniline is converted into violanilin, which is obtained pure by neutralisation of the arsenious and arsenic acid in the melt with caustic soda, driving off the un-converted aniline by a current of steam, separation of the melted violanilin base from the water (formed by condensation of steam), powdering, and drying it. This base is converted with aniline and acetic acid into the spirit-soluble indulin or its base (as described above), which is made soluble with oil of vitriol, similarly as the indulin base from magenta refuse.

Violanilin is also produced by the action of arsenic acid on aniline hydrochloride, or other suitable salts of pure aniline; further, by the action of pure nitro-benzene on pure aniline alone, or mixed with aniline salt, and in general by the action of suitable oxidising or dehydrogenating substances on pure aniline or suitable aniline salts at a temperature of 185° to 190°. Also, for example, by a current of chlorine gas into aniline at 180° to 190°, and then, on the same principle, with a mixture of nitrate of aniline with aniline salt, or by a mixture of nitrate of soda with aniline salt in excess, and so on.

Of course in all these processes some other substances besides violanilin are coming forth, but the latter will be the principal one if the operation is conducted very carefully, and the temperature of forming violanilin does not rise higher than 190°. Above that temperature other decompositions take place, and by-products will be formed to a great extent—as, for example, triphenylen-diamin-blue, &c.—but which to take into consideration would complicate this paper to an enormous extent. Therefore I will only treat on the principal substances formed in the largest proportions by these processes, under the supposition that they are carefully conducted.

As an explanation of the chemical reactions going on in the processes above described I give the following:—

Violanilin is the product of elimination of hydrogen from pure aniline, and simultaneous condensation.

Mauvanilin is the product of elimination of hydrogen and simultaneous condensation of a mixture of two molecules of aniline and one molecule of toluidin.

Both these reactions are represented in the following:—
3 aniline - 6 hydrogen = violanilin.

2 aniline + 1 toluidin - 6 hydrogen = mauvanilin.

The reaction of nitro-benzene on aniline, or aniline hydrochloride, or mixtures of both, is as represented by the following formulæ:—

2 aniline + 1 nitro-benzene = 1 violanilin + 2 water.

And that ...
toluidin—

If there is no hydrochloride of aniline, or of the mixture of aniline and toluidin, and no free aniline or toluidin to be acted upon, then the process must be watched very carefully, and by all means be kept below 190°, else a large quantity of by-products is formed, much easier than in the same process without hydrochloric acid. Even a sudden reaction (especially on a large scale) may take place, producing a rise of temperature by itself up to 140° at once, and forming a large quantity of several by-products. Therefore, if the temperature should rise above 190° the mixture should be cooled down by a thin stream of water whilst agitated, and by these means the temperature should be kept within the limits given above.

The conversion of violanilin with or without mauvanilin into spirit-soluble indulin is caused by the substitution of one, two, or three hydrogen atoms in the violanilin appendant by phenyl.

If acetate of violanilin with or without mauvanilin heated with aniline for blue to 140° to 160°, then ammonia is formed, and the above-named substitution takes place, producing in the first instance the mono-phenyl-violanilin

In the second stage of the process diphenyl-violanilin is formed—

2 aniline + violanilin = diphenyl-violanilin + 2 ammonia

If that process is carried on so far till the formation of ammonia ceases, then a complete substitution of hydrogens in the appendants has taken place, and

3 aniline + violanilin = triphenyl-violanilin + 3 ammonia.

In the most spirit-soluble indulins the triphenyl-violanilin is predominant in quantity; in many of them the mono- and diphenyl-violanilin and mauvanilins accompany it.

Thus, indulin will be principally triphenyl-violanilin hydrochloride :—

By the treatment of these bases and their salts with oil of vitriol, as described above, the four conjugated acids and their salts may be produced.

Sodium triphenyl-violanilin-mono-sulphonate—

Sodium triphenyl-violanilin-disulphonate—

And also the tri- and tetra-sulphonates. And, of course, besides these the corresponding sulphonates of the accompanying compounds are formed simultaneously. The mono-sulphonic acids are insoluble in water, but their alkali salts are easily soluble. The disulphonic acids are only sparingly, but their alkali salts are easily, soluble.

The tri- and tetra-sulphonic acids, and their salts of the phenylated viol- and mauvanilins, are soluble in water, the last the most, and these form the principal constituents of the commercial water-soluble indulins, sometimes containing some of the nigrosin sulphonic acids or their salts.

The properties of the spirit- and water-soluble indulins are very nearly like those of the aniline-blues, and their constitutional formulæ are also much alike.

The spirit-soluble indulin dyes wool, silk, cotton, and other fibres grey in various shades, whilst it is difficult to dye black shades with. It is dissolved in acidulated alcohol (or methylated spirit) by boiling. The filtered solution is added to the acidulated cold bath, in which the goods to be dyed are immersed, and which is heated up slowly to the boiling-point, and kept there till the desired shade is reached.

The spirit-soluble indulin dissolves at about 115° in 2 to 3 parts of its weight of glycerin containing 5 per cen.

hydrochloric acid. After it is dissolved water is added slowly under agitation to five times the weight of glycerin, by which means a solution is obtained which can be used for dyeing. But all solutions of spirit-soluble indulin have the disadvantage that the indulin separates quickly in the bath, rendering the dyed shades uneven.

The water-soluble indulins are dissolved in warm water, and the solution given in the luke-warm acidulated bath where the goods had been immersed before, and then the bath is heated nearly up to the boiling-point, and kept there till the desired shades are produced. The water-soluble indulins dye good shades of light and dark greys, even approaching black, which shade to reach fully offers some difficulties, so that they are scarcely used for black-dyeing on a large scale; besides, the black, when reached, is of a dull and inferior shade, and only slightly resists light, air, and soap.

(To be continued.)

ELECTRIC LIGHTING.

THE Report of the Select Committee of the House of Commons on Electric Lighting was issued June 18th. It is as follows :—

The general nature of the electric light has been well explained in the evidence of Prof. Tyndall, Sir William Thomson, Dr. Siemens, Dr. Hopkinson, and others. It is an evolution of scientific discovery which has been in active progress during the whole of this century. Essentially the electric light is produced by the transformation of energy either through chemical or mechanical means. The energy may be derived from a natural force, as, for instance, a waterfall, or through combustion of a material in the cells of a voltaic battery, or of fuel in a furnace. The energy being converted into an electric current, may be used to manifest electric light by passing between carbon points, or by rendering incandescent solid bodies, such as iridium. A remarkable feature of the electric light is, that it produces a transformation of energy in a singularly complete manner. Thus the energy of one-horse power may be converted into gaslight, and yields a luminosity equal to 12-candle power. But the same amount of energy transformed into electric light produces 1600-candle power. It is not therefore surprising that while many practical witnesses see serious difficulties in the speedy adaptation of the electric light to useful purposes of illumination, the scientific witnesses see in this economy of force the means of great industrial development, and believe that in the future it is destined to take a leading part in public and private illumination. There is one point on which all witnesses concurred, that its use would produce little of that vitiated air which is largely formed by the products of combustion of ordinary illuminants.

Scientific witnesses also considered that in the future the electric current might be extensively used to transmit power as well as light to considerable distances, so that the power applied to mechanical purposes during the day might be made available for light during the night. The Committee only mention these opinions as showing the importance of allowing full development to a practical application of electricity, which is believed by competent witnesses to have future important bearings on industry.

So far as the practical application of the electric light has already gone, there seems to be no reason to doubt that it has established itself for lighthouse illumination, and is fitted to illumine large symmetrical places, such as squares, public halls, railway stations, and workshops. It is used in Paris for lighting shops which require a light by which different colours may be distinguished, and has recently been used in England for the same purpose with satisfactory results. Many trials have been made for street illumination with greater or less success.

Compared with gas, the economy for equal illumination does not yet appear to be conclusively established. Although in some cases the relative economy for equal candle power is on the side of the electric light, yet in other cases gas illumination of equal intensity has the advantage. Unquestionably the electric light has not made that progress which would enable it in its present condition to enter into general competition with gas for the ordinary purposes of domestic supply. In large establishments the motors necessary to produce the electric light may be readily provided, but, so far as we have received evidence, no system of central origin and distribution suitable to houses of moderate size has hitherto been established.

In considering how far the Legislature should intervene in the present condition of electric lighting, the Committee would observe, generally, that in a system which is developing with remarkable rapidity it would be lamentable if there were any legislative restrictions calculated to interfere with that development. The Committee, however, are not in a position to make recommendations for conditions which may hereafter arise, but at present do not exist, as to the distribution of electric currents for lighting private houses from a central source of power. No legislative powers are required to enable large establishments, such as theatres, halls, or workshops, to generate electricity for their own use.

If corporations and other local authorities have not power under existing statutes to take up streets and lay wires for street lighting and other public uses of the electric light, your Committee think that ample power should be given them for this purpose. There seems to be some conflict of evidence as to whether the existing powers are sufficient or not. But even in regard to local authorities it would be necessary to impose restrictions upon placing the wires too near the telegraph wires used by the Post Office, as the transmitting power of the latter would be injuriously affected by the too close proximity of the powerful electric currents needed for producing light.

Gas companies, in the opinion of the Committee, have no special claim to be considered as the future distributors of electric light. They possess no monopoly of lighting public streets or private houses beyond that which is given to them by their power of laying pipes in streets. Electric light committed to their care might have a slow development. Besides, though gas companies are likely to benefit by the supply of gas to gas-engines which are well suited as machines for producing electric light, the general processes of gas manufacture and supply are quite unlike those needed for the production of electricity as a motor or illuminant.

The Committee, however, do not consider that the time has yet arrived to give general powers to private electric companies to break up the streets, unless by consent of the local authorities. It is, however, desirable that local authorities should have power to give facilities to companies or private individuals to conduct experiments. When the progress of invention brings a demand for facilities to transmit electricity as a source of power and light from a common centre for manufacturing and domestic purposes, then, no doubt, the public must receive compensation advantages for a monopoly of the use of the streets. As the time for this has not arrived, the Committee do not enter into this subject further in detail than to say that in such a case it might be expedient to give to the municipal authority a preference during a limited period to control the distribution and use of the electric light, and failing their acceptance of such a preference, that any monopoly given to a private company should be restricted to the short period required to remunerate them for the undertaking, with a reversionary right in the municipal authority to purchase the plant and machinery on easy terms. But at the present time the Committee do not consider that any further specific recommendation is necessary than that the local authorities

should have full powers to use the electric light for purposes of public illumination, and that the Legislature should show its willingness, when the demand arises, to give all reasonable powers for the full development of electricity as a source of power and light.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, June 14, 1879.

Prof. W. G. ADAMS, President, in the Chair.

New members:—Mr. Donald Macalister, B.A., and Mr. St. George Lane Fox.

Prof. MACLEOD described a plan for Suppressing the Induction Disturbances in a Telephone Circuit. It is known that a secondary battery, composed of metal plates and sulphuric acid, allows weak currents to pass while stopping those of high tension. Prof. Macleod therefore inserted a secondary battery of platinum plates between the line and the telephone, but this stopped both the induction and the vocal currents. When platinum wires were substituted for the plates, however, the induction currents were stopped, while the vocal currents could be feebly heard.

Dr. O. J. LODGE exhibited his New Reversing Key for Electrometer Work, which is preferable to the ordinary forms, as giving a high insulation, small capacity, and not requiring the hand to approach close to it to work it. It consists of four platinum wires, arranged in pairs crossing one another; one pair crossing between the other two. These are the terminals and contact pieces of the key. The middle pair are supported by an endless silk thread, which runs on two pulleys, one of which is fitted with a handle. On turning the handle to right or left the two middle wires are brought into contact with one or other of the two outer wires, and the current reversed at will. The whole is enclosed in a metal box.

Mr. J. F. MOULTON then demonstrated the results of the experiments of Mr. Spottiswoode and himself on the Sensitiveness of Electric Discharges in Vacuum Tubes. These experiments were undertaken to find the cause of the luminous layers or strata in the discharge, a Holtz machine being employed. It was observed that when feeble currents were drawn from the machine, the discharge could be depressed by laying the finger on the tube, and this depression always occurs with intermittent currents; therefore the feeble currents from a continuous current Holtz discharge themselves like intermittent currents by reason of their feebleness. This sensitiveness of the discharge to the approach of the finger was found to be due to the conductivity and electric capacity of the hand. Electricity, opposite in kind to the discharge, is induced on the finger, and streaming upon the tube neutralises part of the discharge therein. This effect was also shown by means of tinfoil rings round the tube. An intermittent current is of course capable of this static induction on neighbouring conductors. The luminous discharge in a vacuum tube consists of a bright sharp glow at the negative terminal, followed by a dark space, then a hazy bluish light at the positive pole. The striae or layers in these sensitive tubes merely repeat this appearance. They can be artificially produced by placing the fingers, or rings of metal, at intervals along a tube conveying an amorphous discharge; for in this case the induced electricity discharging itself from the fingers breaks up the amorphous discharge into dark and bright layers. In these stratified discharges the electricity appears to travel *per saltum*, or by stepping stones, as one may say, and the glow seems to be a molecular structure, a view which is supported by Mr. Crookes's

experiments. A negative discharge from the finger produces a dark space in the tube discharge, and a positive one a bright line; therefore, one can tell the kind of discharge passing in a tube by laying a finger on it. If the same pole be brought to both ends of a tube a discharge will still take place from each end, and there will be a dark space in the middle; the electricity here seeming to turn back again the way it came. The discharge from a pole through a vacuum tube would therefore appear to be not akin to conduction but to a disruptive discharge. It is a leap in the dark, and the phenomena observed are due to the gaseous nature of the medium. These experiments point to the possibility of completing a circuit by positive electricity alone.

Prof. GUTHRIE suggested that by combining vacuum tubes with the induction balance of Prof. Hughes it might be possible to get an optical balance for measuring inductive capacity.

Dr. HENRY DRAPER, of New York, who is now on a visit to England, then addressed the meeting on his alleged discovery of oxygen in the sun by bright lines in the solar spectrum. He said that hitherto he had not been able to find these lines projecting from the limb of the sun like hydrogen, and his impression is that oxygen resides lower than the reversing layer. He had lately been extending the dispersion of the spectrum of terrestrial oxygen, and from a light of maximum intensity of one candle power had now got a dispersion of 80 inches from A to O. He exhibited two of the original negatives of the solar spectrum, showing the bright lines.

Mr. J. NORMAN LOCKYER congratulated solar science on having so able a worker as Dr. Draper, and remarked that if Dr. Draper proved his case for even two or three O lines it would be sufficient, considering the variability of the spectrum of matter under different physical conditions. He also alluded to traces of carbon which he himself had found in the sun by the dark flutings in the spectrum.

Dr. DRAPER said he did not see why carbon should not give both bright and dark lines.

Mr. SCOTT exhibited a number of coloured photographs done after the method of Mr. Albert, of Munich.

NOTICES OF BOOKS.

A Manual of Organic Chemistry. By HUGH CLEMENTS, of H.M. Civil Service, President of the Amateur Mechanics' Workshops Association, London, and Lecturer on Various Sciences at St. Thomas', Charterhouse, &c. Blackie and Son: London, Glasgow, Edinburgh, and Dublin, 1879.

THE difficulties of an examiner in setting questions, which shall fairly test the real knowledge of a candidate, have of late years considerably increased owing to the large number of text-books "adapted" to examinations which have been published, and serve merely to "cram" the candidate for the time being, with little or no regard to sound instruction. This is especially the case in respect to the examinations of the Science and Art Department. In a great measure, it is true, this is the fault of the system which makes the teacher dependent for his remuneration on the passing capabilities of his students, and therefore necessitates the use of those text-books which are best adapted for getting his men "through."

Such a book is the volume before us, forming one of a large class which has come into being with the rapid mushroom growth of the system of competitive examination. A feature in this Manual which cannot be too strongly condemned is the publication at the end of the book of a series of short answers to all the questions set in Organic Chemistry by the Examiners in the Science and Art Department during the last ten years. This

occupies no less than one-third of the whole volume. A student, therefore, who learns by rote a good selection of these answers runs a fair chance of passing, though his real knowledge may be of the most fragmentary and imperfect kind. As practical examinations are to a certain extent free from the objection which applies to written examinations, it is to be hoped that in the future much greater stress will be laid on practical work than has hitherto been the case. In the meantime it is highly satisfactory to know that the Department is alive to this necessity, and to find that a large percentage of the candidates in practical chemistry at these examinations send up very creditable results, showing that at many science schools a really sound knowledge of chemical analysis is being imparted.

As regards the book itself it is difficult to imagine how anyone who professes to be a teacher and to have experience enough to write a text-book on the subject could employ the arrangement adopted by the author. In many cases compounds are classed together which have little or no connection with one another; thus, under the heading of hydrides of organic radicals we have in the following order:—Hydrocarbons, cyanogen, oxalic acid, oxamic acid, oxamide, hydrocyanic acid, formic acid, and Prussian blue; whilst among organic bases we have cyanic acid. Nor is his plan of describing the apparatus employed in organic analysis, &c., to be recommended. This he does in a final chapter quite apart from the description of the processes themselves. Space also is here wasted unnecessarily in giving a figure of an ordinary "specimen tube" for weighing out the substance for analysis, as well as by drawings of two retorts, the difference between which it is impossible to see, except that in the one the neck is turned to the left and in the other to the right. The notation is exceedingly loose and defective, different symbols for the same or an analogous radical being frequently used indiscriminately, even in the same compound or equation, thus—

But one of the greatest defects in the book is the almost total neglect of the use of structural formulæ, without which a sound knowledge of organic chemistry can never be obtained by the ordinary student. In many even fundamental points the book is also very imperfect. General reactions are not made sufficiently prominent, and no explanation is given of isomerism and polymerism, nor of the difference between empirical and rational formulæ. To the glycols and their derivatives five lines only are devoted, whilst no special reference is made to glycerin, erythrite, mannite, &c., except as regards the identification of glycerin. The relations of the various organic acids to one another and to other compounds are by no means sufficiently insisted on, nor is any evident distinction made between primary, secondary, and tertiary alcohols, nor between the different behaviour of aldehyds and ketones on oxidation. The important series of aromatic compounds are passed over far too cursorily, no reference at all being made to the ortho-, para-, and meta-positions of the side chains in the derivatives of benzol, &c. Anthracen, naphthalen, and all the other important hydrocarbons and their derivatives, containing more than one benzol nucleus, are omitted altogether, except the identification of naphthalen.

But it is in the series of exercises given at the end of the book that the author shows his want of proper chemical training, or he would not set such childish questions as the following, in which and in many others he has evidently tried in how many different ways he could vary the same question:—"What organic substances are soluble in water?" "What insoluble in water?" "Which are soluble in alcohol?" "Which insoluble in alcohol?" "Which partly soluble in alcohol?" "Which insoluble in water but soluble in hot alcohol?" and so on, through quite a long string of such questions on solubilities. Then follows a long series of similar questions on the taste of organic substances, including—

"What organic substances taste peculiar?" More than one-third of all the exercises consist of such strings of questions, and would doubtless exercise the poor student to no small extent. Question (93) would be a puzzler in the way of analysis in most cases; it runs as follows:—"Make a qualitative analysis of the following mixtures:—Beef, or mutton, or blood, or milk, or flour, or oatmeal, or potatoes, or rice, or apples, or oranges, or tea, or coffee, or snuff, or opium, &c.

There are, however, one or two redeeming points, as the section on "Substitution," and especially that on "Organo-metallic Bodies," whilst the introduction of a special chapter on the identification of organic substances—a new feature in text-books on organic chemistry—has long been a desideratum.

CORRESPONDENCE.

ASHES OF WHEAT-BRAN.

To the Editor of the Chemical News.

SIR,—In the CHEMICAL NEWS, vol. xxxix., p. 244, there is an elaborate analysis of the ashes of wheat-bran. It seems to me that it is the "play of Hamlet with the character of Hamlet left out." In the analysis no mention is made of phosphate of alumina. As this compound plays so important a part in the analyses of flour and bread it ought not to have been left out. I have of late paid some attention to the analysis of bran from white English wheat, and I find that it contains—

Silica	3.671
Phosphate of alumina..	0.282
Phosphate of iron .. .	0.760

The percentage of sulphate of calcium should be 0.256, not 1.9567, as given in Mr. Peckham's analysis.—I am, &c.,

J. CARTER BELL.

VOLUMETRIC DETERMINATION OF CHROMIUM.

To the Editor of the Chemical News.

SIR,—In the last number of the Chemical Society's *Journal* there is the description of a process for determining chromium, based on the oxidation of chromium oxide by potassium permanganate in presence of sulphuric acid, also described in the CHEMICAL NEWS, vol. xxxix., p. 131. May I refer the author (Mr. Sell) to the CHEMICAL NEWS, vol. xxv., p. 151, in which I have described the same process for the determination of chromium in chrome iron and steel? The process as described there is in daily use, and gives thoroughly reliable results.—I am, &c.,

WM. GALBRAITH.

Atlas Works, Sheffield, June 10, 1879.

ON COLORIMETRY.

To the Editor of the Chemical News.

SIR,—At a meeting of the Literary and Philosophical Society of Manchester, on January 11, 1876, I proposed a method for estimating colouring matters in solution. Assuming that if we have in solution in equal bulks of a colourless menstruum the same colouring body, the lengths of the columns of fluid necessary to furnish the same colour are inversely as the quantities of the colouring matter present. Practically the method was carried out by the use of movable white disks in the cylinders containing the solutions. My experiments showed fair approximations when one liquid did not differ very much in strength from the other. Further experiments were made with fluids containing large quantities of colouring

matter, and with the white surfaces both external and internal, I find that the law holds through a wider range with the white surfaces external than internal. In a paper which I read before the Physical and Mathematical Section of the Literary and Philosophical Society in April of this year I pointed out the cause of this. As such a method of colorimetry is, I believe, in practical use, I think it well to bring the matter early under notice. The nature of the correction to be applied when the white surfaces are internal may be inferred from the following considerations:—The light which illuminates the surfaces has previously passed through the solution, so that really we are looking at a coloured disk through a coloured solution. Some allowance must be made for this colouration. If q and q' denote quantities of colouring matter, and t and t' the lengths of columns, then for external surfaces we may use the formula, $qt = q't'$. But suppose the surfaces are internal; then we must add to the lengths of the columns an additional length, which would produce the previous colouration. If the fluids compared do not differ much in composition an approximate formula is—

$$q(t+x) = q'(t'+x).$$

The value of x must be determined experimentally by comparing white surfaces seen externally and internally. If the fluids differ much in composition, the correction to be applied to the columns will differ a little on each side, so that a formula $q(t+x) = q'(t'+x)$ will be necessary. In the same paper I have pointed out a method of procedure in colorimetry which, I think, may be serviceable to those commencing experiments, or to those who are not good judges of colour, or in the case of colours which are difficult of comparison.

Given two cylinders containing coloured fluids of different intensities, and we wish to obtain the same tint in both. In the stronger solution start first with a tint darker than the other, and approach gradually to it; stop when the colours seem the same. Probably the columns will be a little too long. Next start in the stronger solution with a lighter tint than the standard solution; approach gradually to this limit, and stop when there seems no difference, probably the column will be too short. Next take the mean of the two columns.

The foregoing remarks apply to colouring matters in solution. A method of colorimetry founded on the same principle is, I believe, applied to turbid solutions. It is very desirable that before general adoption some exhaustive experiments should be made on the limits of its accuracy.—I am, &c.,

JAMES BOTTOMLEY, D.Sc.

Irwell Terrace, Lower Broughton,
near Manchester, June 16, 1879.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances, l'Académie des Sciences. No. 21, June 2, 1879.

Magnetic Impenetrability of Iron.—J. Jamin.—A concentric thickness of 6 millimetres of iron arrests almost completely the magnetic effect of an external helix.

Ultra-violet Limit of the Solar Spectrum.—A. Cornu.—The utmost limit which the author has been able to reach corresponds to the wave-length 293.

Alkaline Amalgams and on the Nascent State.—M. Berthelot.—The author remarks that we possess hitherto very vague notions on the conditions of molecular mechanics which determine and regulate the use of alkaline amalgams. He has therefore undertaken their

thermic study. Sodium amalgam with water shows +32.6 cals., and potassium amalgam +27.0 cals. per equivalent of metal dissolved. With hydrochloric acid so diluted that 1 equiv. = 2 litres the results were for sodium +46.5, and for potassium +41.2 cals. The alkaline amalgams in hydrogenising reactions always disengage more heat than does free hydrogen. This thermic excess explains the hydrogenising power of amalgams, and throws a light upon the general theory of the reactions formerly ascribed to the nascent state.

Stanno-propyls and Iso-stanno-propyls.—MM. A. Cahours and E. Demarçay.—The use of an alloy containing less than 10 per cent of sodium yields a mixture of the diiodide of distanno-propyl and of the moniodide of tristanno-propyl, the separation of which is scarcely possible. To obtain the former of these compounds pure the product of the reaction of propyl-iodide upon tin must not be distilled except in a vacuum. Its composition is represented by $\text{Sn}_2(\text{C}_6\text{H}_7)_2\text{I}_2$. The iodide of tristanno-propyl is $\text{Sn}_2(\text{C}_6\text{H}_7)_3\text{I}$. The properties of these compounds are described at length.

Quantity of Nitric Acid Contained in the Water of the Nile before and after its Rise.—M. d'Abbadie.—The quantities of nitric acid per litre of water before, during, and after the floods are represented as being 0.01, 0.0038, and 0.002 grm.

Origin of Sound in the Telephone.—Th. du Moncel.—It is certain that the induction currents produced by a Bell's telephone can occasion the reproduction of speech in a magnetic disk surrounded with a helix without any need for a diaphragm influenced by such disk.

Rays of the Vapour of Sodium.—Mr. N. Lockyer.

New Arrangement for Increasing the Sensibility of the Vibrating Plate of the Telephone.—M. C. Decharme.—The author proposes to fix such plates by their centre only.

A Compound of Alumina and Carbonic Acid.—MM. Urbain and Renoul.—If alumina is precipitated from alum by means of sodic carbonate two bodies are obtained differing in aspect according as the liquid was boiling or of the common temperature of the atmosphere. In the former case the precipitate is gelatinous, transparent, and filters slowly, whilst in the latter case it is opaque, separates readily from the liquid, and absorbs colouring matters much more abundantly than the transparent variety. The author finds that the opaque variety contains carbonic acid in such proportions that it may be represented by the formula, $\text{CO}_2, 2\text{Al}_2\text{O}_3, 8\text{H}_2\text{O}$.

Mr. Lawrence Smith remarked that a natural carbonate of alumina and soda existed at Montreal.

Bulletin de la Société Chimique de Paris,
No. 10, May 20, 1879.

Oxy-ferrocyanide of Ammoniacal Copper.—Antony Guyard.—The precipitate obtained by adding potassic ferrocyanide to ammoniacal sulphate of copper if washed and dried in the air at about 150° loses cyanogen and ammonia, absorbs oxygen, and takes a violet tone. The material should be spread out in a thin layer, and stirred continually till the heat reaches 170°, when the reaction is complete. The colour does not seem available either in painting or in the pigment style in calico-printing. If heated up to 200° the colour changes to a blue, and at from 240° to 250° to a green, neither of them remarkable for brightness.

A Law Peculiar to the Metallic Ferrocyanides.—Antony Guyard.—The hydrated oxides, as existing in their soluble salts, may be divided into two great groups according to their behaviour with aqueous ammonia:—
1st. Oxides soluble in ammonia and in ammoniuretted ammoniacal salts, including, of course, the tartrate.
2nd. Oxides insoluble, or very sparingly soluble, in ammoniuretted ammoniacal salts, but, on the other hand,

soluble in ammoniacal tartrate. The former group is precipitated, and generally very completely, by potassic ferrocyanide, whilst those of the latter group remain perfectly dissolved in the basic ammoniac tartrate.

Volumetric-Chemical Studies.—W. Ostwald.—The contractions or dilatations experienced on mixing the solutions of salts may serve for the measurement of their respective affinities, and have furnished the author with results analogous to those obtained with the calorimeter by M. Berthelot and M. Thomsen.

Atti della R. Accademia dei Lincei.

Fasc. 4, March 1879.

Researches on Cinchonin.—Prof. Filetti.—The author dissolved 15 grms. cinchonin in a slight excess of hydrochloric acid, diluted the solution to 4 litres, saturated it with chlorine, and exposed it to the direct action of light. A white or slightly yellow substance was deposited on the sides of the beaker. This deposit dissolves in glacial acetic acid, and is re-precipitated by water. On heating cinchonin with bromine and water for several days in a closed tube he obtained products, the examination of which is still incomplete.

*Verhandlungen des Vereins zur Beförderung des
Gewerbflusses.* April, 1879.

This number contains no chemico-technological matter.

MISCELLANEOUS.

The Royal Society.—On Thursday, the 12th inst., the following fifteen candidates were elected Fellows of the Royal Society:—J. Anderson, M.D., Rev. M. J. Berkeley, H. Bessemer, Prof. A. Crum-Brown, W. L. Buller, Sc.D., G. H. Darwin, Prof. J. D. Everett, Prof. F. S. B. François de Chaumont, Prof. G. D. Liveing, G. Matthey, G. J. Romanes, A. Schuster, Ph.D., Prof. H. G. Seeley, B. Williamson, and T. Wright, M.D. The following have been elected Foreign Members of the Society:—Arthur Auwers, Berlin; Luigi Cremona, Rome; Jean Louis Armand de Quatrefages, Paris; Georg Hermann Quinke, Heidelberg; Theodor Schwann, Liege; Jean Servais Stas, Brussels.

NOTES AND QUERIES.

Liquid Perchloride of Iron.—I should be glad if any of your correspondents could tell me where there is a good market for liquid perchloride of iron in quantities (sp. gr. 1.400⁰), and the price that would be given. Also protochloride of iron (sp. gr. 1.400⁰). Have convenience for making large quantities.—SCARLET.

MEETINGS FOR THE WEEK.

MONDAY, 23rd.—Royal Geographical, 8.30.
TUESDAY, 24th.—Anthropological, 8.
WEDNESDAY, 25th.—Society of Arts, 4. (Anniversary.)
Geological, 8.
THURSDAY, 26th.—Royal Society Club, 6.30. (Anniversary.)
FRIDAY, 27th.—Quekett, 8.
SATURDAY, 28th.—Physical, 3.

THE YORKSHIRE COLLEGE.

The Worshipful Company of Clothworkers of the City of London having increased their Endowment of the Textile Industry Department of the College so as to include instruction in Dyeing, the Council of the College is prepared to receive applications for the post of Instructor; Stipend, £300 a year and half the Fees. Preference will be given to Candidates who are familiar with the processes of French and German Dyeing and with the Methods of Instruction pursued in the Continental Schools. Applications, accompanied by a statement of the Candidate's experience, together with copies of Testimonials, to be sent not later than August 11th to the Secretary of the Yorkshire College, from whom further information may be obtained. The work of instruction will begin in January, 1880.

Leeds, June 18th, 1879.

W. F. HUSBAND, Secretary.

Analytical Chemist desires an appointment.
Would be willing to make himself useful in any capacity; London preferred.—Address, Chemist, 351, Middleton Road, Oldham.

A German Chemist (Ph.D.), holding diplomas from University and Polytechnicum, who has already had experience in a manufactory, seeks a Situation in a Chemical Manufactory in England.—Address, K.D., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

Required by an Associate of the Royal School of Mines, F.C.S., &c., a Situation in a Laboratory, or as Manager of a Chemical or Metallurgical Works, or on a Mine, in England or abroad. Highest references.—Address, A.R.S.M., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TO MANURE MANUFACTURERS.

FOR SALE.—About 150 tons Monthly of Woolen Shoddy; free from grease; containing nitrogen equal to from 5 to 10 per cent ammonia.—Apply to David Shaw and Co., Clayton, near Manchester.

Superior Iron Filter-Press for Sale, made to order and of extra quality, by Messrs. Needham and Kite. It contains ten chambers, each 19×21½ inches; is provided with a 3-inch gun-metal pump to work by hand or steam, and with fittings for washing and steaming, which can be used or not at discretion. The whole is quite equal to new, and is in perfect working order.—Address L. B. S., CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

TANK WAGGONS.—Wanted two for Crocoite; secondhand if in good condition.—Full particulars to be addressed "Tank," CHEMICAL NEWS Office, Boy Court, Ludgate Hill, London, E.C.

A Part or the Whole of Excellent Laboratory Fittings to be Sold with the Lease of an Eligible Dwelling-House. Rent very moderate.—Further particulars of E. and S. Smith, Auctioneers and Agents, 22, Southampton Buildings, Chancery Lane, W.C.

DAVID HILL, CONSULTING CHEMIST in Technical Processes, late of Deans Terrace, South Shields. Letters to be addressed care of Messrs. Bulloch and Co., 79, Mark Lane, London, E.C. Special attention given to questions relating to "Noxious Vapours."

WILLOUGHBY BROS., CENTRAL FOUNDRY, PLYMOUTH, Makers of Plant for Sulphuric Acid and Superphosphate Works, also for Tar and Ammonia Distilling.

NORRINGTON'S PATENT,

For the prevention of escape of gases during the charging of kilns and nitre pots. The success of this invention being assured, we are prepared to Contract for fixing this Patent Apparatus to Pyrites Furnaces throughout the Kingdom.

Estimates and Plans furnished on application.

Silicates of Soda and Potash in the state of Soluble glass, or in CONCENTRATED SOLUTION of first quality, suited for the manufacture of Soap and other purposes, supplied on best terms by W. GOSSAGE and Sons, Soap Works, Widnes, Lancashire.

London Agents, COSTE and Co., 19 and 20, Water Lane, Tower Street, E.C., who hold stock ready for delivery.

TO PROFESSORS & EXPERIMENTALISTS.

W. STONE, Mathematical, Surveying, and Optical Instrument Maker, 44, Gloucester Street, Queen's Square, Bloomsbury, works out all kinds of difficult experimental and scientific work.

S. A. SADLER, CLEVELAND CHEMICAL WORKS, MIDDLESBROUGH;

Newfall Tar Works, Carlton;
Ammonia Works, Stockton-on-Tees;
and Stamshaw Chemical Works, Portsmouth.

And also of the Furness Tar Products Co., Ulverston.

Manufacturer of Benzole, Toluole, Xylol, Solvent and Burning Naphthas, Carbolic Acid and Disinfecting Powder, Refined Anthracene, Naphthaline, Black Varnish, Refined Tar, Crude Liquid Ammonia, Coal-Tar, Pitch, Crocoite, Grease, Sulphate of Ammonia, Pyroligneous Acid, Acetate of Lime, Wood Naphtha, Charcoal, &c., &c.

S. A. S. is always a buyer of Coal-Tar Naphthas, Crude Anthracene and all Tar Products.

All communications to be addressed to the offices at Middlesbrough.

NOTICE—ARTIFICIAL ALIZARINE

London 18th June 1879

WE the undersigned the Owners respectively of the Patents for the Manufacture of Alizarine

A D 1869 No. 1936
A D 1869 No. 1948
A D 1869 No. 2218

HEREBY GIVE NOTICE That we recently commenced Legal Proceedings against The Alizarine and Anthracene Company Limited for damages for the infringement of the above-mentioned Patents and for an Injunction to restrain the said Alizarine and Anthracene Company Limited from manufacturing, selling or from offering for sale or disposing of or parting with any Artificial Alizarine or other Coloring Matters manufactured or prepared in contravention of our rights under the said Patents of either of them respectively and that after obtaining an interim injunction on the terms of our application we at the request of the said Alizarine and Anthracene Company Limited agreed to stay our Action upon the following terms

- That the said Alizarine and Anthracene Company Limited should submit to a perpetual Injunction
- That they should admit the validity of the said Patents
- That they should pay damages for past infringements
- That they should pay our Costs of the Legal Proceedings

A perpetual injunction against the Alizarine and Anthracene Company Limited have been granted and all proceedings in the Action have been stayed on the above terms

AND WE HEREBY GIVE FURTHER NOTICE that we recently were about to institute legal proceedings against Messrs. Arthur and Henshaw Drysalters and Oil Merchants in Glasgow and Matthew Clark and William Andrew Jamieson Drysalters and Oil Merchants Glasgow the individual partners of the said firm of Arthur and Henshaw to obtain interdict against their infringing the said Letters Patent or any of them and damages for infringements thereof by them in time past and that we have agreed to discontinue and discharge the said threatened proceedings upon certain conditions embodied in an Agreement entered into between us and them Under the said Agreement the said Messrs. Arthur and Henshaw and the said Matthew Clark and William Andrew Jamieson the individual partners of the said firm admit and acknowledge

- That the said Letters Patent are valid in every respect
- That they have infringed the said Letters Patent by importing and selling Artificial Alizarine manufactured according to one or other of the processes described in the Specifications respectively filed in connection with the said Letters Patent
- That the Letters Patent of the 28th May 1869 No. 1642 granted to Frank Julius Brönnner (therein named Julius Brönnner) and Hermann Gutzkow are and always have been null and void
- They undertake during the subsistence of our said Letters Patent not to import into or sell within the United Kingdom any Artificial Alizarine produced by any of the processes described in the Specifications of any of our said Letters Patent except with our consent in writing

WE LASTLY GIVE NOTICE that any person or persons infringing our above-mentioned Patents whether by purchasing (except from us or our Licensees) or selling importing or being concerned in importing or in anyway using Artificial Alizarine in the United Kingdom other than Alizarine made here by us or imported by us or our Licensees will be immediately proceeded against

A REWARD will be given to any person who will give the undersigned information sufficient to undertake legal proceedings against any such Infringers

BURT BOULTON and HAYWOOD
64 Cannon Street City London
Badische Anilin und Soda Fabrik

MINERALOGY AND GEOLOGY.

NEW LIST of Collections of Minerals, Fossils, and Rocks, with prices. New List of Minerals for Chemical Purposes, Manufacture, and Research. New List of Varieties of Rocks. New List of Prices and Sizes of Cabinets for Natural History and other purposes. New Catalogue of Secondhand and New Books on Geology and Kindred Sciences. New Supplementary List of Books. New List of Sections of Rocks and Minerals for the Microscope. New List of Prices and Patterns for Geological Hammers. New List of Blowpipe Cabinets, Apparatus, and Materials. Also Implements and Appliances for practical work in Geology and Mineralogy.

Post free on application to JAMES K. GREGORY, Geologists and Mineralogists' Repository, 88, Charlotte Street, Fitzroy Square, London.

IMPORTANT TO SULPHURIC ACID MANUFACTURERS. NORRINGTON'S PATENT.

In the ordinary method of Manufacture, at the time of charging the Kilns, a considerable escape of gases takes place. This is attended with proportionate loss of Sulphur, and with much inconvenience to the workmen, as well as annoyance to the vicinity of the Works. This may be entirely avoided by the adoption of C. Norrington's patented invention, which can be applied at moderate cost to existing Plant, as well as in the erection of new Works. It may be seen in full operation on extensive Plant at Messrs. C. Norrington and Co.'s Chemical and Manure Works, Cattedown, Plymouth, where the fullest information may be obtained, with terms for cense.

THE CHEMICAL NEWS.

VOL. XXXIX. No. 1022.

LIMITED OXIDATION OF THE ESSENTIAL OILS.

THE ATMOSPHERIC OXIDATION OF TURPENTINE.

By E. T. KINGZETT.

1. In my previous papers,* which were communicated to the Chemical Society and the British Association, I have shown that when the so-called essential oils are exposed to atmospheric oxidation, peroxide of hydrogen is produced in an indirect manner. In the case of turpentine, which was more particularly studied, it seemed to me that a camphoric peroxide ($C_{10}H_{14}O_4$) is first formed, and that this is slowly decomposed by the action of water, yielding peroxide of hydrogen and camphoric acid, thus—

Certain it is that I obtained camphoric acid in my experiments, and analysed some of its compounds. I also succeeded in showing that all hydrocarbons of the formula $C_{10}H_{16}$ (terpenes) similarly give rise to the formation of peroxide of hydrogen, and that this property is shared by menthene, $C_{10}H_{18}$. On the other hand, it was observed that the hydrocarbons of the formula $C_{15}H_{24}$ did not behave in this way. The production of peroxide of hydrogen by the atmospheric oxidation of the specified hydrocarbons seemed to have some kind of connection with another property of the same bodies. It had been shown by Oppenheim and Wright that all the terpenes yield cymene ($C_{10}H_{14}$) when subjected to suitable processes, and, moreover, it appears that cymene as obtained from all sources is identical. According to Fittica, cymene is normal propyl-methyl-benzene, in which the methyl and propyl occupy the *para* position. This view has not received universal acceptance, but whatever it may be worth, there is apparently no satisfactory reason for doubting the identity of cymene prepared from different compounds, and the researches of Paterno lend particular confirmation to this statement.

Now, since all the terpenes and menthene give peroxide of hydrogen as above stated, and since they also contain a cymene nucleus, the two facts seem to be related, and this relation is confirmed by my observations, that cymene itself yields peroxide of hydrogen also, while the hydrocarbon from oil of cloves, $C_{15}H_{24}$ (Church), does not yield peroxide of hydrogen and (as I anticipated would be the case) does not yield cymene by bromination (as shown by Wright).

In the last part of my research the general features presented in the atmospheric oxidation of turpentine on a large scale were described in detail, and it was then shown that the compound which is primarily formed, and which afterwards (*viz.*, when in contact with water) gives rise to the formation of peroxide of hydrogen, may be obtained in such amount that when the oil of turpentine containing it is subjected to distillation decomposition occurs just above the boiling-point with almost explosive violence. As is well known, the atmospheric oxidation of turpentine is now conducted as a commercial operation (for producing the disinfectant called "Sanitas"), and I have been naturally anxious to continue my experiments in order to obtain a more perfect knowledge of the process and its products. Unfortunately, the performance of other duties has largely

interrupted my work, and even now I am only induced to make this preliminary communication, since, from a paper read at the last meeting of the Chemical Society, I perceive that Dr. Armstrong is working in some measure upon the same subject.

Having said so much, I will now give the notes of my recent experiments, all of which I intend to repeat and work out to their final conclusions as opportunity may offer and time permit.

2. There is a great difference presented by different essential oils, and even by various kinds of turpentine, as regards the rate at which they individually absorb oxygen from the air; and not only is this the case, but an oil of turpentine which, say, absorbs oxygen at a given rate, will absorb it much less rapidly if freed from contained oxidised matters by distillation. In other words, when once the process has begun, it continues more and increasingly rapidly, so that the greater the amount of oxidised matter contained in the oil the greater the oxidation under given conditions. The following table is interesting as illustrating the relative absorptive rates for atmospheric oxygen presented by the various oils experimented with. The method employed was as follows:—

A number of very long tubes (made from combustion tubing) and sealed at one end, were charged with equal volumes of air, water, and the various oils. After exposure to sunlight of summer for a number of hours, and before all the oxygen was absorbed in any case, the tubes were removed to the laboratory and the residual gas in each tube measured. Calling the largest amount of oxygen absorbed 100, then—

	Absorbed.
(a) Russian oil of turpentine	100.0
(b) Swedish " " " " " " " "	100.0
(c) Some oil which I obtained in Switzerland ..	89.4
(d) American oil of turpentine	78.9
(e) Oil of Eucalyptus	75.0
(f) An evidently adulterated Swedish turpentine	52.6
(g) " Scotch distilled American turpentine " "	42.1

The oils *a*, *b*, *d*, and *e* were undoubtedly genuine commercial oils; the oil *c* was perhaps French oil of turpentine, and in this case only was the oil distilled before use, because to my knowledge it had undergone great oxidation by keeping for many years; the oils *f* and *g* were evidently not genuine, and had been sent to me merely as samples; I should say that both had been adulterated with so-called pine oil of commerce. It may be mentioned that when the oils which absorbed atmospheric oxygen at the relative rates indicated by 100, 100, 78.9, and 75 were taken in equal amounts and placed in cylindrical glasses having their tops covered with paper treated with the same amount of the same mixture of potassic iodide and starch, the papers became coloured owing to the formation of peroxide of hydrogen in their vicinity in the same order. The same general result has been obtained in oxidising very large quantities of the same oils for commercial purposes.

3. In Parts II. and IV. I have described the general nature and characters of the aqueous solution which is obtained when oil of turpentine is, in the presence of water, exposed to the action of a blast of air, and it is therefore unnecessary to do the same thing again in this place. If this solution be evaporated on the water-bath to dryness, of course all the acetic acid is got rid of, and all the peroxide of hydrogen is decomposed. There remains behind a dark coloured matter, which when hot has a sugar-like odour and is viscid; on cooling it sets into an adhesive but firm mass, which, when treated with concentrated sulphuric acid, gives a colour reaction somewhat resembling that bearing Pettenkofer's name.

To get some sort of knowledge of its composition a part of the substance was dried at 100° C.,* and burnt with

* Part I.—*Journal of the Chemical Society*, June, 1874. Part II.—*Ibid.*, March, 1875. Part III.—*CHEMICAL NEWS*, vol. xxxii., p. 133. Part IV.—*Ibid.*, vol. xxxiv., p. 127.

* The weight did not become constant, the substance being evidently slowly volatile at 100° C. After being in the oven for forty or fifty hours the residual substance lost 10 per cent during the next forty hours.
